$$dF' = F\,p\,v \times v \times dt = F\,p\,v^2\,dt = \frac{F\,p\,g\,H^2\,dt}{D + H} \quad \text{(18)}$$

The work, dF', represents the loss of energy of the tidal wave per unit of length in the time, dt. Hence,

$$dE = -\,dF' = -\frac{F\,p\,g\,H^2\,dt}{D + H} \quad \text{(19)}$$

It can be shown from theoretical considerations that the energy of any section of wave of unit length may be expressed as,

$$E = \rho\,g\,l\,H^2 \quad \text{(20)}$$

If x is the distance of propagation in the channel, $\frac{dx}{dt} = C = \sqrt{g\,(D + H)}$; whence,

$$dt = \frac{dx}{\sqrt{g\,(D + H)}} \quad \text{(21)}$$

Differentiating Equation (20), substituting for dt in Equation (19) its value from Equation (21), and simplifying,

$$dE = \frac{(D + H)^{\frac{3}{2}}\,dH}{H} = -\frac{F\,p\,dx}{2\,\rho\,l\,\sqrt{g}} \quad \text{(22)}$$

By integrating Equation (22), an expression is obtained which shows how the height of a wave of translation in a canal of infinite length and constant section is reduced from the effects of frictional resistance as the wave is propagated along the axis of x.

Equation (22) may be expanded and reduced as follows:

$$\frac{D^{\frac{3}{2}}\,dH}{H} + \frac{3}{2}\,D^{\frac{1}{2}}\,dH + \frac{3}{8}\,\frac{H\,dH}{D^{\frac{1}{2}}} - \frac{1}{16}\,\frac{H^2\,dH}{D^{\frac{3}{2}}} + \ldots = -\frac{F\,p\,dx}{2\,\rho\,l\,\sqrt{g}} . \quad (23)$$

As the expanded equation is rapidly convergent, all terms after the third may be omitted in practice. Integrating Equation (23),

$$D^{\frac{3}{2}}\log_e H + \frac{3}{2}\,D^{\frac{1}{2}}\,H + \frac{3}{16}\,\frac{H^2}{D^{\frac{1}{2}}} - \frac{1}{48}\,\frac{H^3}{D^{\frac{3}{2}}} + \ldots = -\frac{F\,p\,x}{2\,\rho\,l\,\sqrt{g}} + \text{a constant} \ldots\ldots\ldots\ldots (24)$$

When $x = 0$, let $H = H_0$; then,

$$D^{\frac{3}{2}}\log_e H_0 + \frac{3}{2}\,D^{\frac{1}{2}}\,H_0 + \frac{3}{16}\,\frac{H_0^{\,2}}{D^{\frac{1}{2}}} - \frac{1}{48}\,\frac{H_0^{\,3}}{D^{\frac{3}{2}}} + \ldots = \text{a constant} \ldots . (25)$$

Subtracting Equation (24) from Equation (25),

$$D^{\frac{3}{2}}\log_e\left(\frac{H_0}{H}\right) + \frac{3}{2}\,D^{\frac{1}{2}}\,(H_0 - H) + \frac{3}{16}\,\frac{(H_0^{\,2} - H^2)}{D^{\frac{1}{2}}} - \frac{1}{48}\,\frac{(H_0^{\,3} - H^3)}{D^{\frac{3}{2}}} + \ldots = \frac{F\,p\,x}{2\,\rho\,l\,\sqrt{g}} \ldots\ldots\ldots\ldots\ldots (26)$$

which is the desired formula.

Equation (26) shows that the wave would be propagated in an infinitely long canal for an infinite distance; that is, theoretically, the continually reducing effect of friction would cause the wave to disappear only at an infinite distance; but, practically, it would disappear within appreciably finite distances. Except for friction the wave would be propagated indefinitely at full volume. However, the effect of friction is continually to reduce the volume of the wave by a varying quantity per foot. Assuming for the moment that this lost water could be held at the point at which it was left behind by a single positive wave, it would appear upon the original canal surface as a thin wedge, thickest at the canal entrance, and diminishing to zero only at an infinite distance. Actually, of course, this water left behind by the wave in its travel will tend to flow back to the source and add its volume to that of the succeeding negative wave.

Since waves of translation may be either positive or negative, a depression in the water surface may be propagated as a wave, as well as an intumescence, in which case the height of the wave, h, will have a negative value. Since Equation (26) is of general application, by giving proper positive and negative values to H, curves will be found which will be the theoretical loci of high and low tide for the infinitely long canal. (See Fig. 2.) It is apparent at once that these curves are not symmetrical. The effect of friction in destroying the wave is greater for the negative than for the positive wave, since the depth of water is less in the canal during the propagation of such a wave.

Time Required for Crest of Wave to Reach a Given Point.—If Equation (21) is written, $\frac{x}{t} = C = \sqrt{g\,(D + H)}$, the rate of propagation to a given point is found to depend on the height of the wave which, due to the action of friction, is variable. If, however, the values of C are computed for given values of H selected quite close together, the rate of propagation, C, may be assumed constant between these points, and a mean value for the points in question may be assumed as correct without appreciable error. This gives a new value, C', for the rate of propagation between two such points,

$$C' = \frac{1}{2}\sqrt{g}\left[\sqrt{D + H_1} + \sqrt{D + H_2}\right] = \frac{(x_1 - x_2)}{t} \dots\dots (27)$$

whence,

$$t = \frac{2\,(x_1 - x_2)}{\left(\sqrt{D + H_1} + \sqrt{D + H_2}\right)\sqrt{g}} \dots\dots\dots\dots\dots (28)$$

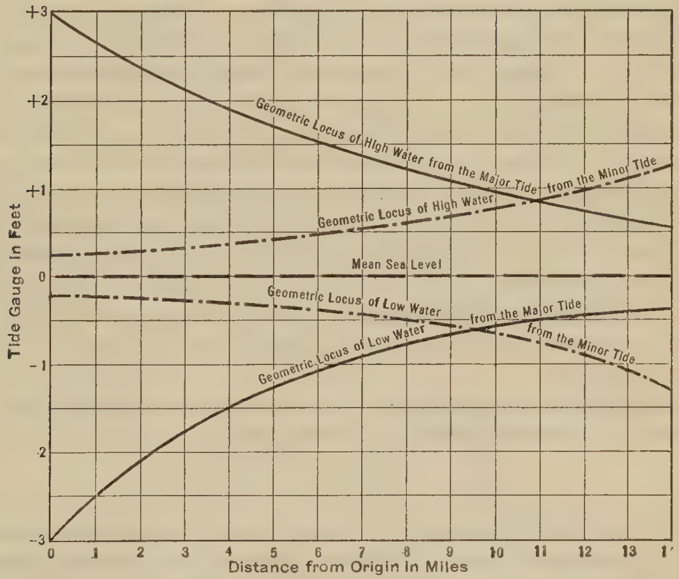

FIG. 2.—GEOMETRIC LOCI OF HIGH AND LOW WATER FOR TWO SIMULTANEOUS WAVES PROPAGATED IN A CANAL OF INFINITE LENGTH.

For the negative wave, of course the values of H in Equation (28) would be negative.

The equations show that, considering friction, the rate of propagation, or the speed, falls off as the wave progresses, and the wave constantly tends to check its speed. Furthermore, this effect is greater for the negative than for the positive wave.

If, therefore, a series of successive waves of translation, positive and negative alternating, are being propagated in the canal one would expect to find the positive waves tending to outrun the negative waves slightly, the effect being the more apparent the greater the distance traveled.

Energy.—The total energy of a wave of translation,[12] or the work which it could do in being brought to a state of rest, would be constant were it not for friction; but while continually reduced by friction, the remaining energy at any point of an indefinite canal consists of two equal parts, potential energy as represented by the height of the intumescence above the mean level, and kinetic energy as represented by the velocity of the mass of water. The expression for the potential energy of one unit of length of wave is $\frac{1}{2} \rho g l h^2$, and that for its kinetic energy is $\frac{1}{2} \rho l (D + h) v^2$. The equality of these two kinds of energy may be made apparent by substituting in the latter expression for v its value from Equations (13) and (15). This equality of energy may be upset, however, by any cause which impresses a change upon either height or velocity of the wave.

The equality of these two manifestations of energy is absolute and unchangeable in a simple wave of translation not affected by another wave. The existence, in conjunction or opposition, of two or more waves of translation in the same channel may apparently change the manifestations; but the total energy displayed at any point will always be the sum of the energies of the two waves. This total energy may be manifested partly or entirely either as potential energy or as kinetic energy, but the conversion of one kind into the other follows definite laws and can be predicted and evaluated from the characteristics of the two simple waves affecting each other. Manifestly, the total energy of one wave is not affected by that of another, although the latter may act to convert potential energy to kinetic energy, or *vice versa,* thus changing the external character of both waves, giving the resultant a different height and velocity.

For the energy of a given simple wave the sum of the potential and kinetic energy may be expressed algebraically as follows,

$$E_1 = \frac{1}{2} \rho g l H_1^2 + \frac{1}{2} \rho l (D + H_1) V_1^2 \ldots\ldots\ldots\ldots (29)$$

Now assume that two waves, E_1 and E_2, are superimposed in the same channel with the same phase. The total energy of the resultant wave at this point can be neither more nor less than the sum of the energies of the component waves, neglecting friction; hence,

$$E_3 = E_1 + E_2 = \frac{1}{2} \rho g l (H_1^2 + H_2^2) + \frac{1}{2} \rho l (D + H_1 + H_2)(V_1^2 + V_2^2) \ldots (30)$$

It will be noted that in Equation (30) the total resulting depth of water $(D + H_1 + H_2)$, is used instead of $(D + H_1)$ or $(D + H_2)$. In compound waves, the total depth must always be used in computing the respective velocities of component waves from their respective heights. Failure to do so would involve an error in the expression for the total amount of kinetic energy.

It will be interesting to see whether any change as between kinetic and potential energy has occurred in this superposition. Assume, in accordance with the usual understanding as to the formation of a resultant wave from two components, that $E_3 = E_1 + E_2$; $H_1 + H_2 = H_3$; and $V_1 + V_2 = V_3$. If the resultant wave is assumed to be a simple wave of translation, its equation will be similar to Equation (29), thus:

---

[12] "Hydraulique," par Flamant, Paris, 1923, p. 434.

$$E_3 = \frac{1}{2} \rho \, l \, g \, H_3^2 + \frac{1}{2} \rho \, l \, (D + H_3) \, V_3^2 \ldots\ldots\ldots\ldots (31)$$

or,

$$E_3 = \frac{1}{2} \rho \, l \, g \, (H_1^2 + 2 \, H_1 \, H_2 + H_3^2)$$

$$+ \frac{1}{2} \rho \, l \, (D + H_1 + H_2) \, (V_1^2 + 2 \, V_1 \, V_2 + V_2^2) \ldots\ldots\ldots (32)$$

Subtracting Equation (31) from Equation (30) to solve for V_3 and H_3, $V_3^2 = \sqrt{V_1^2 + V_2^2}$ and $H_3^2 = \sqrt{H_1^2 + H_2^2}$.

This result seems to be at variance with the understanding previously expressed, that when one wave is superposed upon another the resulting heights and velocities are equal to the sum of the respective heights and velocities of the component waves. In Equation (32) if $H_1 = H_2$, and hence $V_1 = V_2$,

$$E_3 = 4 \left[\left(\frac{1}{2} \rho \, l \, g \, H_1^2 \right) + \frac{1}{2} \rho \, l \, (D + 2 \, H_1) \, V_1 \right] \ldots\ldots\ldots (33)$$

which is twice as great as the actual energy available in the two waves. Such a result violates the principle of the conservation of energy and is manifestly incorrect. It invalidates the assumption that in the case of superposed waves the resultant height is the sum of the component heights, and the resultant velocity is the sum of the component velocities. In other words, the resultant wave can not conform to the assumptions made.

Next, assume the two equations expressing the relations, $V_1 = \dfrac{\sqrt{g} \, H_1}{\sqrt{D + H_1 + H_2}}$ and $V_2 = \dfrac{\sqrt{g} \, H_2}{\sqrt{D + H_1 + H_2}}$. Multiplying these together, $V_1 \, V_2 = \dfrac{g \, H_1 \, H_2}{D + H_1 + H_2}$, and, consequently,

$$\frac{1}{2} \rho \, l \times 2 \, V_1 \, V_2 \, (D + H_1 + H_2) = \frac{1}{2} \rho \, l \, g \times 2 \, H_1 \, H_2 \ldots\ldots (34)$$

Subtracting Equation (34) from Equation (30),

$$E = \frac{1}{2} \rho \, l \, g \, (H_1 + H_2)^2 + \frac{1}{2} \rho \, l \, (D + H_1 + H_2) \, (V_1 - V_2)^2 \ldots (35)$$

It is apparent that if $H_1 + H_2 = H_3$, then must $V_1 - V_2 = V_3$, or if $V_1 + V_2 = V_3$, then must $H_1 - H_2 = H_3$, in order that the principle of conservation of energy may not be violated. From these results one may infer that any energy that may appear to have been added as a reinforcement to the actual height of the resultant wave must disappear as a loss from the total energy of the velocities of the component waves, or *vice versa*.

The general conclusions to be drawn from these facts are that:

1.—For two or more waves traveling together in conjunction, one wave is formed, the height and velocity of which are equal to the square root of the sum of the squares of the respective component heights and velocities.

2.—For waves traveling in opposite directions at the points of conjunction, if both waves are either positive or negative, the heights will be the sum of the heights of the component waves, and the velocity will be the difference between the component velocities.

3.—If one wave is positive and one negative—that is, if the waves are in opposition—the resultant height will be the difference between the component heights, and the resultant velocity will be the sum of the component velocities.

Influence of Change of Width.—Consider next the effect upon the tidal wave of an abrupt change in the width of a canal.

Let the canal, *A B*, in Fig. 3, with a width, l, suddenly become narrower at *B*, so that its width is l' in the section, *B C*. If h_0 is the height of the generating wave at *A* and h_1 is its height as reduced by friction at *B*, then the energy of the wave at *B* will be $E = \rho\, g\, l\, h_1^2$. Due to the reduced width of *B C*, only a portion of this energy can be propagated into *B C*. Let the actual height of the tide at *B* equal h; then, this energy, E_1, is equal to $\rho\, g\, l_1\, h^2$.

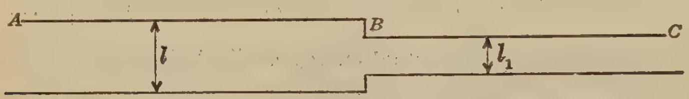

FIG. 3.—PLAN OF CANAL WITH SUDDENLY CONTRACTED SECTION.

The energy which is not transmitted past *B* will manifest itself in a reflected wave traveling back from *B* toward *A*, and will have the effect at *B* of raising the water level at that point higher than it would have been had the width been constant, and it accounts for the difference between h_1 and h.

Therefore, this reflected energy may be expressed by the formula,

$$E_2 = E - E_1 = \rho\, g\, (l\, h_1^2 - l_1\, h^2) = \rho\, g\, l\, (h - h_1)^2 \quad \text{........} (36)$$

Reducing,

$$l\, h_1^2 - l_1\, h^2 = l\, h^2 - 2\, l\, h\, h_1 + l\, h_1^2$$

and,

$$h = \frac{2\, l\, h_1}{l + l_1} \quad \text{..........................} (37)$$

If l_1 is less than l, h will be greater than h_1; for example, if $l_1 = 0$, $h = 2\, h_1$. If l_1 is greater than l, h will be less than h_1; for example, if $l_1 = \infty$, $h = 0$. In the former case the reflected energy is positive and causes an additional rise in level between *A* and *B*. In the latter case, energy is abstracted from the canal, or the reflected energy is negative, and causes a lowering of level between *A* and *B*.

THEORY OF THE INTERFERENCE OF TWO OPPOSED WAVES

It is desirable to consider theoretically the results of superposing two tidal waves that are propagated in opposite directions in a horizontal canal of uniform section and infinite length, neglecting the effects of friction.[13] It will be assumed that the waves are of the class called periodic, exactly sinusoidal, and of the same length, and that, conformably with theory, the velocities of the currents which they generate are approximately proportional in any vertical to the height of the wave referred to its mean level.

Under these conditions, it is easy to find the instantaneous profiles as well as the distribution of the velocities of the resulting wave during the entire period of its propagation. Considering as positive the heights of the two component waves above the mean level, it will only be necessary to add them algebraically to obtain the corresponding heights of the resulting wave. Likewise, the distribution of the velocities in the wave will be obtained by adding algebraically the velocities of the component waves in the same vertical. Those in the direction of the propagation of the wave which has the largest vertical amplitude, are considered positive and those which have an opposite direction are negative. There are then three relative positions of the two waves to be considered principally.

First consider what happens in such a case when the waves are in coincidence, or in conjunction.

In Fig. 4, let *A* 2 *C* 2 *E* be a wave being propagated toward *E*, and let *E* 1 *C* 1 *A* be a wave being propagated toward *A*. Since both waves are tidal, they will have equal lengths, and there will be points such as *A*, *C*, and *E*, at which their points of zero elevation will arrive simultaneously. It is evident that these points will be spaced at distances apart equal to one-half a wave length. Half way between these points, and, consequently, distant from them by one-quarter of a wave length, there will be points, *B* and *D*, at which the maximum height of each wave will arrive simultaneously.

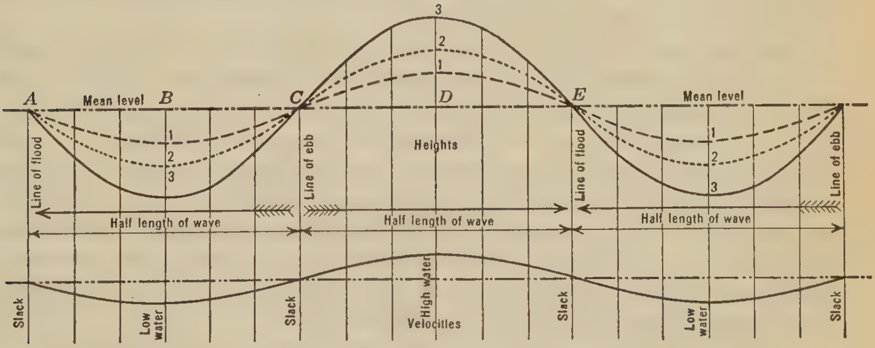

FIG. 4.—POSITION OF WAVES AT MOMENT OF THEIR CONJUNCTION.

Now, if the two opposed waves are exactly equal in amplitude, the sum of their heights at *A*, *C*, and *E* will always be equal to zero; that is, the waves will interfere perfectly at those points during the complete tidal period and there will be no variation in level, while at the half-way points the resultant wave will have an amplitude equal to the sum of their amplitudes, or to twice their common amplitude. On the other hand, at *A, C,* and *E,* the respective velocities will add their values to give a new velocity equal to twice that of a single wave, while at *B* and *D* the velocities will annul each other, being equal in value and opposite in direction.

---

[13] "Etude du Régime de la Marée dans La Manche," Bourdelles, *Annales des Ponts et Chaussees*, 1899, 3^{me} trimestre.

Then, the surface of the hypothetical canal, when subjected to the action of two equal and opposed waves, will present the appearance of being subdivided into sections the length of one half wave in which the surface oscillates up and down in amplitudes increasing from zero value at *A* to a maximum at *B* and then decreasing to zero again at *C,* and so on indefinitely.

At the same time the mass of water in the canal will flow to and from the points, *B* and *D,* increasing in velocity in both directions from these points as a starting place to a maximum at *A, C,* and *E,* but always decreasing to zero again at *B* and *D* and reversing this action in the next half of the wave.

Points such as *A, C,* and *E* are nodes, and *B* and *D* are summits. Therefore, as a result of the interference of two opposed equal waves, there is a series of alternating nodes and summits, the surface variations being zero and the velocities greatest at the nodes, and the surface variations greatest and the velocities zero at the summits.

This state of affairs gives rise to a resultant wave termed the stationary wave or "chop." It is called stationary because the wave form does not progress in the canal, but remains fixed in position, and it is always characterized by these peculiarities. Its special laws will be summarized later.

For waves of unequal height in conjunction, the crests and the troughs of the two component waves will be found in the same vertical, the swells of the waves being in the same phase. (See Fig. 4.) In this position, the vertical amplitude of the resultant wave is a maximum and is equal to the sum of the amplitudes of the component waves.

While the waves are in conjunction, the heights at *A, C,* and *E* will be zero, but just as soon as the moment of conjunction has passed, this will no longer be true as it was in the case when the two opposed waves were equal in amplitude. Fig. 5 shows the condition existing one hour after conjunction. Since the component heights are not equal, perfect interference does not occur at those points, but the resultant has a value which in this case is positive at *A* and *E,* and negative at *C.* The point of zero elevation or mid-tide departs from the points, *A, C,* and *E,* as the instant of conjunction passes, and moves at a varying rate of speed toward the next point of zero elevation or mid-tide, arriving there at the next instant of conjunction.

At the instant of conjunction, the velocity at the points, *A, C,* and *E,* will be zero, or it will be slack water, while at the points, *B* and *D,* half-way between, where the tidal variation is greatest, there will not be a slack in the current as there would be if the two opposed waves were equal. At these points there will be, however, a velocity equal to the difference between the velocities due to each component wave. It is clear from Fig. 5 that after the instant of conjunction the lines of slack water and of strength of tide also move from their respective initial positions, and progress at varying rates of speed toward the positions proper for the next instant of conjunction. (See Fig. 6.)

FIG. 7.—POSITION OF WAVES AT MOMENT OF THEIR OPPOSITION.

The second relative position of the waves which it is important to notice, is that which corresponds to the coincidence, in the same vertical of the trough of one with the crest of the other, the swells of the wave being in opposition in their phases (Fig. 7). In this case, the amplitude of the resultant wave is a minimum; it is equal to the difference of the amplitudes of the component waves, being zero for waves of equal heights. On the contrary, the velocities in the different portions of the wave are greatest and are equal to the sum of the corresponding velocities of the component waves. This position succeeds the preceding one after three hours, during which each one of the waves has progressed a distance equal to one-quarter of its length. The nodes of equal waves correspond to those points at which the least variation in height occurs in the case of unequal waves.

Instead of a stationary wave, a new progressive wave is formed, which will be propagated through the canal in a different manner from either component wave. This progressive wave will have points of minimum heights corresponding to nodal points accompanied by maximum velocities, and points of maximum heights corresponding to summits accompanied by minimum velocities; but none of these heights or velocities remains permanently at zero, although their values pass through zero twice in each complete cycle.

As the waves pass a point, such as *A* (Fig. 4), after coinciding at mid-tide, the point of mid-tide stage will move slowly from *A* toward *C*, accelerating its rate of motion until the point of opposition, *B*, is reached, the exact acceleration being dependent on the height of the minor wave. Then, slowly losing its velocity, it will arrive at *C* at the time of the next phase coincidence, the average speed being equal to that of the components. The point of zero velocity will also move in a like manner from *B* toward *C*.

The length of the resultant wave is necessarily equal to that of the components, but the velocity of propagation or speed of the resultant wave is not constant as is that of the components. Thus, the summits of the three waves are in the same vertical at the moment of their conjunction. The resultant wave is then out-distanced by that component which is propagated in the same direction; then it rejoins it at the moment of opposition at which the summits of the three waves find themselves again in the same vertical.

All other relative positions of the two component waves are intermediate between these two, both as to heights and as to velocities. Figs. 5 and 6 show the positions of two unequal opposed waves for the two hours included in the interval which separates the two positions already mentioned. Figs. 4, 5, 6, and 7 thus represent the positions of the waves during the three successive hours of their propagation. It is easy to deduce from these curves the circumstances of their superposition during the entire period of their passage in the canal considered.

Among all these circumstances, the one which deserves the most attention, relates to the turn of the currents; that is, to their change of direction. It is to be noted that these turns are effected at the point of the resultant wave located on the vertical where the surfaces of the component waves meet. Furthermore, when this point is found in that portion of the resultant wave corresponding to the falling tide, the currents diverge or separate from that point which marks what is termed the "line of separation" of the currents, or "line of ebb". They approach or meet when the point of intersection occurs on that portion of the resultant wave corresponding to the rising tide, marking the line termed the line of meeting of the tide, or the "line of flood".

The lines of separation or of meeting are equally spaced at a distance of one-half wave length. Upon these lines the currents turn; their velocity increases with the distance from these lines, and it is a maximum at the halfway point between them.

In the resultant wave, the currents turn at half-tide at *A, B, C, D,* and *E,* and they reach their strength at the high and at the low water at the moment when the component waves are superposed at *B* and *D* and when in opposition at *A, C,* and *E* (Figs. 4 and 7). For all other points in the canal, the turns of the currents occur a greater or less time after half-tide, depending on the hour, or the position of the component waves, and the strength of the current comes one-quarter of the tidal period later. When the waves are equal, the currents turn simultaneously throughout the entire canal.

Therefore, if the water of the infinitely long canal is subjected to the action of two unequal and opposed waves, its surface will present the appearance of transmitting a wave having a direction and average speed equal to that of the major wave, but which will continually vary in speed and amplitude as it progresses. Furthermore, its velocity in any given vertical will not be in direct proportion to the amplitude at that point. The phenomenon of the interference of two opposed waves, having the same horizontal amplitude, the same speed of propagation, and the same period, but of different vertical amplitude, lends itself easily to mathematical demonstration.[14]

Assuming that, at the instant $t = 0$, the two profiles of the waves pass through the origin of co-ordinates taken upon the mean level, with the axis of x in that level, and that they correspond to the conjunction of the two waves which would accordingly be in the same phase—the equations of the profiles of the two waves would be:

$$y_1 = H_a \sin 2\pi \left(\frac{x}{L} - \frac{t}{T}\right)$$

and,

$$y_2 = H_b \sin 2\pi \left(\frac{x}{L} + \frac{t}{T}\right)$$

In these equations, L is the length of each of the waves; T, their period; and H_a and H_b, their semi-amplitudes above and below the mean level. The ordinate, y, of the resultant wave is:

$$y = y_1 + y_2 = H_a \sin 2\pi \left(\frac{x}{L} - \frac{t}{T}\right) + H_b \sin 2\pi \left(\frac{x}{L} + \frac{t}{T}\right) \quad (38)$$

Let,

$$K^2 = H_a^2 + H_b^2 + 2 H_a H_b \cos \frac{4\pi t}{T}$$

and,

$$\tan \frac{2\pi\phi}{L} = \frac{H_a - H_b}{H_a + H_b} \tan \frac{2\pi t}{T} \quad (39)$$

---

[14] "Hydraulique," Flamant, Paris, 1923, p. 486.

then Equation (38) can be written in the form:

$$y = K \sin \frac{2\pi}{L}(x - \phi) \qquad (40)$$

It follows from Equation (40) that at every point the maximum amplitude of oscillation has a special value, dependent upon the position of the point, and that it is comprised between $H_a + H_b$ and $H_a - H_b$. The maximum amplitude, $H_a + H_b$, is found at intervals equal to L, and the minimum amplitude, $H_a - H_b$, at the middle point of these intervals. At a given point, the duration of a complete oscillation is always equal to T. Likewise, at a given instant, the total length of the undulation is always equal to L; its mean speed of propagation is, therefore, equal to that of each of the component waves, but the speed varies with time. Differentiating Equation (39):

$$\frac{d\phi}{dt} = \frac{\frac{L}{T}}{\frac{H_a - H_b}{H_a + H_b}\sin^2\frac{2\pi t}{T} + \frac{H_a + H_b}{H_a - H_b}\cos^2\frac{2\pi t}{T}} \qquad (41)$$

which is a minimum for $t = 0$, $t = T$, etc., and a maximum for $t = \frac{T}{2}$, $t = \frac{3T}{2}$, etc.

The meeting points of the component waves and the positions of the lines of flux are found from the equality, $y_1 = y_2$; whence, $H_a \sin 2\pi\left(\frac{x}{L} - \frac{t}{T}\right) = H_b \sin 2\pi\left(\frac{x}{L} + \frac{t}{T}\right)$, which gives,

$$\tan 2\pi\frac{x}{L} = \frac{H_a + H_b}{H_a - H_b}\tan 2\pi\frac{t}{T} \qquad (42)$$

Equation (42) shows that the lines are spaced at one-half wave length apart. The speed of their displacement is given by the expression,

$$\frac{dx}{dt} = \frac{\frac{L}{T}}{\frac{H_a - H_b}{H_a + H_b}\cos^2\frac{2\pi t}{T} + \frac{H_a + H_b}{H_a - H_b}\sin^2\frac{2\pi t}{T}} \qquad (43)$$

which is minimum for $t = \frac{T}{2}$, $t = \frac{3T}{2}$, etc., and a maximum for $t = 0$, $t = T$, $t = 2T$, etc.

When the two waves have the same vertical amplitude, $H_a = H_b$, the resultant motion is the "chop". Its special laws which result from the preceding equations are summarized as follows:

1.—At the instant of conjunction, the velocities are annulled, or slack-water prevails for the entire length of the canal, and the amplitude of the resultant wave is double that of the component waves.

2.—At the instant of opposition, the velocities reach their maximum in all that part of the canal where the mean level prevails. There is no change of level produced, during the entire tide, at those points corresponding to the summits of the waves in opposition, and the velocity there is greater than elsewhere.

3.—The positions of the lines of flux and of reflux remain invariable for the entire tide; they coincide with that of the summits of the waves in conjunction.

General Remarks.—It must be recognized that theory, even if perfect, would still remain inadequate to solve completely the complex problems which the regimen of the tide raises in practice. The ideal canal is not found in Nature; waterways have a more or less irregular bed, and almost always they have a length less than that of the tidal wave which traverses it. This latter fact alone has hitherto sufficed to upset all theories, because the tidal wave cannot be propagated in them as has been assumed for an infinitely long canal. In this hypothetical canal the waves always travel forward, without mutually disturbing each other; each one before and after its passage finds and leaves any point in its original condition; they then disappear without leaving any trace of their existence. It is not so when the length of the canal is limited; in introducing itself the wave encounters the effects of preceding waves; the circumstances of its propagation, consequently, are modified by reason of these effects, which will be found impossible to follow in all their consequences. A complex and variable regimen results from all this, according to circumstances, controlled by the length and characteristics of the bed, which it seems must forever escape satisfactory analysis.

On the other hand, by a consideration of the theoretical canal, it is possible to treat some of the influences which affect the tidal wave, and to forecast what general effect may be expected from variations of length, width, depth, and the material of the bed of the canal. By means of this study it is possible to determine relative if not absolute values of such effects. It is in this spirit that the problem is approached in the following pages.

PROPAGATION OF THE TIDE IN A CANAL COMMUNICATING WITH AN INFINITELY LARGE RESERVOIR

Insufficiency of Theory That Flow Caused by Surface Slope Accounts for Tidal Flow.—Assume a horizontal canal of constant cross-section communicating at one of its ends with the sea, and at the other with a reservoir sufficiently large to be considered as infinite; that is, so large that its level remains constant. Let $A B$ in Fig. 8 be the mean level of the sea assumed to be the same as that of $B C$ in the hypothetical reservoir, and A_2, A_4, the extreme levels attained by the tide. Assume that, at a given instant, a state of equilibrium of the entire liquid mass is established, the level of the sea being at A, and the surface of the water horizontal for the entire length of the canal. Suppose the level then rises to A_1. If it should remain immobile for a sufficiently long time at this point, a permanent motion would be set up in the canal between A and B, defined by the equations of constant uniform flow. The free surface between these points would take the form of a curve tangent at A_1 to the horizontal, and convex upward.

However, things do not happen in this manner. The level is constantly variable and the permanent regimen, corresponding to any such height as A_1, never has time to become established. Even the state of equilibrium which was assumed when the level was at A, at the height, $B C$, would never be realized unless the level should remain motionless at A for a sufficiently long time.

During the period when the level rises from A toward A_2, it reaches some height A_1, before the water entering through the mouth can have filled completely the triangle, AA_1B. It rises relatively faster at A than at any other intermediate point between A and B, and the curve of level takes a concave form upward, such as that shown by the broken line in Fig. 8.

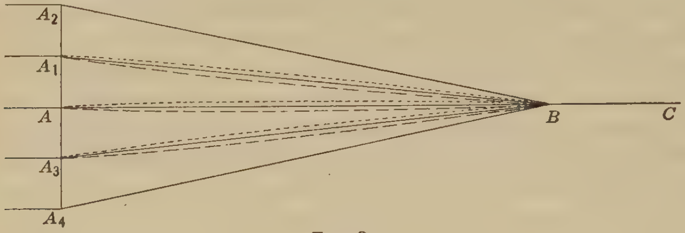

FIG. 8.

On the other hand, when the level falls from A_2 toward A, as it is continually variable, it leaves any position before the corresponding permanent state can become established in the canal, and the curve of level is then convex upward, as is shown by dotted lines. The convexity of this curve will be even greater than that which would correspond to a permanent regimen.

The same effects will be produced in the portion of the oscillation that takes place below the level of equilibrium, between A and A_4. When the level comes to A_3 in falling, the surface of the water in the canal is convex upward and, conversely, it is concave when the level passes through A_3 in rising. The curves in broken lines then represent the levels during the flood, and those in dotted lines, the levels during the ebb.

Under these conditions, the velocities at each point of the canal will be nil because of reversal at the moment of half-tide, when the level passes through the mean level; they will be a maximum, whether on the flood or the ebb, at the moment the difference of level is greatest.

The phenomenon is in reality much less simple than the preceding description might indicate. The tidal wave is not transmitted instantaneously in the entire length of the canal, so that the high waters, the slack waters, and the low waters are not simultaneous in the entire stretch. They are successive because of the retardation of the propagation of the wave. The speed of this propagation itself is different from what it would be in a canal of constant depth. If the level of the sea is considered to be held motionless during a sufficient time at a height, A_1, and the corresponding permanent regimen is established with a certain mean velocity of flow, U_1, an undulation created at A_1 will be propagated toward B with a speed greater by U_1, approximately, than that which would correspond to the depth. On the other hand, the tidal wave entering into the canal possesses a certain energy which, except for the losses due to friction, remains constant. Because the depth diminishes from A_2 toward B an increase of the velocities results from the constancy of this energy, which again has for a consequence an increase of the speed of propagation. For this reason, the speed of propagation of the wave and the velocities of the water will be greater in the following sections than they would be in a horizontal canal with free surface and of the same depth as this section; and the difference will go on increasing as the point, B, is approached. (From the origin of the canal toward the point, A, this speed of propagation and the velocities will have adjusted themselves with regard to local circumstances and to the depth corresponding to the level, A_2.)

Influence of an Infinitely Large Reservoir.—What influence is exerted upon the wave of translation by the intervention at any point of an infinitely large reservoir? This hypothetical body of water has been defined as one sufficiently large to be unaffected by the emptying of the volume of the tidal wave into it. Consequently, its surface remains at a constant level, which is also assumed to be the mean level of the tidal sea and of the canal.

Equation (20) shows that no matter what the energy per unit length of the wave may be, the square of its height will vary inversely with the width of the canal, l. It follows from this and from the demonstration given under the heading, "Influence of Change of Width" (see Fig. 3), that if the width of the canal is made very large, h will become very small. Since the reservoir constitutes an infinite expansion in the width of the canal, l becomes very large, approaching infinity, and h becomes correspondingly small, approaching zero. Therefore, the wave of translation, whether positive or negative, must disappear at the outlet of the canal into the reservoir. Observation reveals that not only does the wave disappear at the outlet, but that the influence of the reservoir in decreasing the height of the wave is reflected back for the entire length of the canal, causing both heights and velocities at all points in the canal to differ from their theoretical values.

Explanation.—To find an explanation of this phenomenon, it is desirable to revert to the theory of the propagation of the tide in a canal as being formed by a series of elementary waves of translation, or successive fluxes and refluxes. Neglecting friction, the first flux being created on the rising tide would propagate itself indefinitely without change, until it reached the reservoir, where it must disappear. The flux is propagated at a definite speed through the canal, and a certain period is required to elapse from the time it appears at the entrance of the canal until it disappears at the outlet. Why does not the flux manifest itself simultaneously throughout the canal immediately upon its appearance? The answer, of course, is that the front or anterior portion of the flux must successively overcome the friction of the banks and the resistance or inertia opposed to its propagation by each particle of water in the canal. The height and the form of the flux are moulded by these resistances. The decrease of these resistances of inertia and the sudden cessation of all resistance to the flux upon entering into the reservoir permit a more rapid speed of propagation between the entrance and the outlet; but even this more rapid speed is never instantaneous, and a certain time would be required for the surface of the flux to acquire the slope it would assume if it were allowed time to establish the conditions of permanent flow. The flux is accompanied by a given velocity of flow of the water in the canal to supply the intumescence. The cessation of the forces of inertia opposing the flux then results in an increase of this velocity of flow.

Now, if a piston that just fits the cross-section of the canal were inserted at any point and given a push in a direction to increase the volume already flowing under the influence of the flux, the effect of this applied energy would be to generate a negative wave propagating itself in the direction opposite to that of the flux. This would be in addition to the positive wave propagated in the same direction, which for the time being is neglected.

The cessation of the resistances of inertia at the outlet will have the same effect as the piston or the addition of energy as assumed, thus creating a negative flux at the outlet which is propagated back through the canal toward the entrance.

The height of the negative flux (or depression) at the outlet will be exactly equal to that of the flux, so that their sum shall be zero, and the resultant velocities of the two fluxes, being in the same direction, will add their effects. Hence, the final velocity will be twice the theoretical, which is the velocity that would correspond to the computed height of the wave of translation for the point in question under the assumption of an infinitely long canal.

Source of the Energy Generating the Negative Flux.—The energy of the wave of translation is reduced only by friction, and in the infinitely long canal it will consist of equal parts of potential energy represented by the height of the wave and of kinetic energy as represented by the velocity of the water. Under proper conditions one kind of energy is convertible into the other; yet the total sum of available energy at any given point is constant.

The hypothetical reservoir is of sufficient size to absorb all the energy of the wave, with no effect upon it, and the energy represented by velocity of the water is expended at the outlet in the whirls, boils, and eddies that usually occur when flowing water is brought to rest in still water. If no change had occurred in the flux until it had reached the reservoir, one-half its energy, (kinetic), would have been so expended. The other half, the potential, must be converted into kinetic energy before it can be dissipated in this manner, and it is this energy being converted into kinetic energy—manifested by increased velocities of the water—which generates the opposed negative flux.

Resultant Effect.—Each flux following the first must be subject to the same requirement of disappearance in the reservoir, and must generate an opposite negative flux. Hence, it follows that, as the complete wave of translation is being propagated toward the reservoir, it is being continually modified by an opposed negative wave propagated from the reservoir toward the sea, and generated by the influence of the reservoir upon the original wave.

A similar reasoning would show that the negative wave of translation propagated from the sea toward the reservoir, and which may be said to absorb energy from the water into which it is propagated, will, when reaching the reservoir, cause an opposite positive wave to be generated there which will be propagated toward the sea.

A rigorous application of this reasoning would lead to the conclusion that the propagation of a single positive wave through the canal would result in an infinite series of alternating positive and negative waves being set up. Each positive wave from the sea would generate a corresponding negative wave from the reservoir, and *vice versa*. Under the influence of friction, however, each succeeding wave would become smaller and smaller, so that the series would finally die out, for all practical purposes. The resultant profile of the canal at any instant would be the algebraic sum of all the wave heights at that instant, and the resultant velocity would be the sum of all the velocities.

Formula for the Variation of the Tide at a Given Point.—At a given point the cycle of variation of any wave surface, being a result of the great ocean tidal wave, will be expressed approximately by a sinusoidal law, and its trace may be expressed by the equation,

$$Y = H \cos 2\pi \left(\frac{t - t_x}{T}\right) \ldots\ldots\ldots\ldots (44)$$

Each point of the canal will have a different set of values for H and t_x. It is likewise manifest that values of H and t_x for the same point will be different for the positive and negative waves.

Changing the point of origin for counting the time, t_x, and computing the time, t_y, for the propagation of a wave from the reservoir toward the sea, the same formulas can be used to compute the variation of the reflected wave from the reservoir to the sea, the proper constants being inserted in the general equations.

Let t_L be the time required for the positive wave to be transmitted from the sea to the reservoir, and t_y the time required for the reflected negative wave to be transmitted to the point represented by a given set of values of H and t_x (the factor, $-H'$, being the corresponding value of the height of the reflected wave at that point), the following is the equation of the variation of the reflected wave at the same point:

$$-Y' = -H' \cos 2\pi \left(\frac{t - (t_L + t_y)}{T}\right) \ldots\ldots\ldots (45)$$

Adding Equations (44) and (45), the actual height, h, of the tide at the selected point at the time, t, is,

$$h = Y - Y' = H \cos 2\pi \left(\frac{t - t_x}{T}\right) - H' \cos 2\pi \left(\frac{t - (t_L + t_y)}{T}\right) \ldots (46)$$

This equation may be written in the shorter form,

$$h = \sqrt{H^2 + H'^2 - 2 H H' \cos 2\pi \left(\frac{t_x - (t_L + t_y)}{T}\right)} \cos 2\pi \left(\frac{t - t_m}{T}\right) . (47)$$

in which, t_m may be found from the equation,

$$\tan 2\pi \frac{t_m}{T} = \frac{H \sin 2\pi \frac{t_x}{T} - H' \sin 2\pi \left(\frac{t_L + t_y}{T}\right)}{H \cos 2\pi \frac{t_x}{T} - H' \cos 2\pi \left(\frac{t_L + t_y}{T}\right)} \ldots\ldots (48)$$

It will be observed that t_m is that value of t for which h will be a maximum. It, therefore, represents the time required for the resultant wave to be propagated from the sea to the point considered.

It is evident from the preceding that for any number of reflected waves that may be considered, a general expression for the resultant wave may be written as follows:

$$h = H_1 \cos 2\pi \left(\frac{t - t_1}{T}\right) + H_2 \cos 2\pi \left(\frac{t - t_2}{T}\right)$$
$$+ H_3 \cos 2\pi \left(\frac{t - t_3}{T}\right) + \ldots + H_n \cos 2\pi \left(\frac{t - t_n}{T}\right) \ldots\ldots\ldots (49)$$

When any two waves simultaneously affect the same point and their heights are additive because they have the same sign, the resultant velocity must be the difference between the component velocities. A general formula, similar to Equation (49), may be written for the resultant velocity at the same point, as follows:

$$V = V_1 \cos 2\pi \left(\frac{t - t_1}{T}\right) - V_2 \cos 2\pi \left(\frac{t - t_2}{T}\right)$$
$$- V_3 \cos 2\pi \left(\frac{t - t_3}{T}\right) - \ldots - V_n \cos 2\pi \left(\frac{t - t_n}{T}\right) \ldots\ldots\ldots (50)$$

in which, V_1, V_2, V_3, etc., are found directly from the corresponding values of H_1, H_2, H_3, etc., by means of the equation,

$$V_n = H_n \sqrt{\frac{g}{D + h}} \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (51)$$

the value of h being that given by Equation (49).

Equation (49) may be made to represent conditions at the outlet of the canal into the reservoir by making substitutions, as follows: $H_2 = -H_1$; $H_4 = -H_3$; $H_n = -H_{n-1}$; $t_1 = t_2$; $t_3 = t_4$; and $t_{n-1} = t_n$. Likewise, Equation (50) may be written so as to represent velocities at the same point by substituting $V_2 = -V_1$; $V_4 = -V_3$; and $V_n = -V_{n-1}$. At the sea entrance to the canal, $H_1 = H_0$; $H_3 = -H_2$; $H_5 = -H_4$; $H_n = -H_{n-1}$; $t_1 = 0$; $t_2 = t_3$; $t_1 = t$; $t_n + 1 = t_n$; $V_1 = V_0$; $V_3 = -V_2$; $V_5 = -V_4$; and $V_n = -V_{n-1}$.

In a similar manner Equations (49) and (50) may be applied to all other points in a tidal canal opening into a tideless reservoir by changing signs in alternate (second, fourth, sixth, etc.) quantities. Thus, in Equation (49), change the sign from plus to minus in alternate quantities, in which n is even. Conversely, under the same circumstances change the sign from minus to plus for alternate quantities in Equation (50).

To determine the values of t for which these values of h and v are maxima, differentiate the equations with reference to t, place the first differential equal to zero, and solve for t, the particular value of which will be designated t_m:

$$\frac{dh}{dt} = -H_1 \sin 2\pi \left(\frac{t - t_1}{T}\right) + H_2 \sin 2\pi \left(\frac{t - t_2}{T}\right)$$
$$- H_3 \sin 2\pi \left(\frac{t - t_3}{T}\right) \ldots \mp H_n \sin 2\pi \left(\frac{t - t_n}{T}\right) = 0 \ldots\ldots (52)$$

whence, $\tan 2\pi \frac{t_m}{T}$ equals,

$$\frac{H_1 \sin 2\pi \frac{t_1}{T} - H_2 \sin 2\pi \frac{t_2}{T} + H_3 \sin 2\pi \frac{t_3}{T} \ldots \pm H_n \sin 2\pi \frac{t_n}{T}}{H_1 \cos 2\pi \frac{t_1}{T} - H_2 \cos 2\pi \frac{t_2}{T} + H_3 \cos 2\pi \frac{t_3}{T} \ldots \pm H_n \cos 2\pi \frac{t_n}{T}} \ldots (53)$$

Similarly, for t_{mv}, the time of maximum velocity, $\tan 2\pi \frac{t_{mv}}{T}$ equals,

$$\frac{V_1 \sin 2\pi \frac{t_1}{T} + V_2 \sin 2\pi \frac{t_2}{T} - V_3 \sin 2\pi \frac{t_3}{T} \ldots \mp V_n \sin 2\pi \frac{t_n}{T}}{V_1 \cos 2\pi \frac{t_1}{T} + V_2 \cos 2\pi \frac{t_2}{T} - V_3 \cos 2\pi \frac{t_3}{T} \ldots \mp V_n \cos 2\pi \frac{t_n}{T}} \ldots (54)$$

It is quite evident that the value of t_m for heights is not the same as that of t_{mv} for velocities, and, therefore, the time of maximum velocities will not coincide with the time of maximum or of zero heights.

After $-V_{n-1}$ has been substituted for V_n in Equation (50) it is possible to evaluate the frictional coefficient, F, in an easy and rapid manner. Combining it with Equation (51):

$$V = 2\, V_1 \cos 2\pi \left(\frac{t - t_1}{T}\right) = 2\, H_1 \sqrt{\frac{g}{D + h}} \cos 2\pi \left(\frac{t - t_1}{T}\right) \ldots (55)$$

Whence,

$$H_1 = \frac{1}{2} V_0 \sqrt{\frac{D}{g}} \ldots\ldots\ldots\ldots\ldots (56)$$

in which, V_0 equals the maximum value of V occurring when $t = t_1$. The value of V_0 can be measured readily at the outlet by any of the usual methods of determining the maximum mean velocity, and this value when determined enables H_1 to be found from Equation (56). Then when H_1 is substituted in Equation (26), in which all factors except F will be known, the frictional coefficient for the particular case will be given. Bonnet found this value to be 2.48 for the Scheldt River (0.51 English measure). The writer has found 3.05 (or 0.60 English measure) to be the usual value for canals of 6 to 12 ft. in depth, while Bonnet's value appears to apply to larger canals, such as the Cape Cod and the Suez Canals.

Since the direct and reflected waves at the outlet have all their ordinates exactly equal and of opposite sign, thus completely annulling each other, it is apparent that they are in opposition at that point, and that the time of maximum velocity corresponds to the time when the maximum ordinates are in opposition. The instant of this occurrence, therefore, measured from the time when the wave entered into the canal at its mouth, gives the time, t_1, consumed by the wave in propagating itself from the mouth to the outlet, and this time can also be determined by observation.

In Equation (50) change the signs of the alternate second, fourth, sixth, etc., quantities from negative to positive and divide by $\sqrt{\frac{g}{D + h}}$. To the result add Equation (49) with the signs of alternate second, fourth, sixth, etc., quantities changed from positive to negative. The resulting equation, simplified, takes the form,

$$h + v \sqrt{\frac{D+h}{g}} = 2\, H_1 \cos 2\,\pi \left(\frac{t - t_1}{T}\right) \ldots\ldots\ldots\ldots\ldots (57)$$

Now, $v \sqrt{\frac{D+h}{g}}$ may be considered as the height of a simple wave of translation which alone would give rise to a velocity, v; it will be designated the velocity height and represented by h_v.

Equation (57) then takes the form,

$$h + h_v = 2\, H_1 \cos 2\,\pi \left(\frac{t - t_1}{T}\right) \ldots\ldots\ldots\ldots\ldots\ldots (58)$$

Equation (58) is general, and will be true for any moment, at any point on the canal. The conclusion is drawn from it that in a uniform canal communicating with a tidal sea at one end, and with a tideless basin at the other, the actual height of the water in the canal at any instant plus a height equivalent to the velocity of the water at the same instant will be equal to double the height of the original wave of translation as it would have been transmitted at the same instant in a canal of infinite length; that is, in the hypothetical canal as defined in this paper.

Similarly, if Equation (50) is multiplied by $\sqrt{\frac{g}{D+h}}$ and added to Equation (49) as before (with alternate signs changed), the resulting equation takes the form:

$$v + \frac{\sqrt{g}\, h}{\sqrt{D+h}} = 2\, V_1 \cos 2\,\pi \left(\frac{t - t_1}{T}\right) \ldots\ldots\ldots\ldots\ldots (59)$$

In Equation (59), $\frac{\sqrt{g}\, h}{\sqrt{D+h}}$ equals a velocity which would be due to the height, h, in an infinitely long canal of the same dimensions. Denoting this quantity by v_h,

$$v + v_h = 2\, V_1 \cos 2\,\pi \left(\frac{t - t_1}{T}\right) \ldots\ldots\ldots\ldots\ldots\ldots (60)$$

From Equation (60) it is conclusive that the velocity at any point in the canal at any instant, added to the velocity which would accompany—in an infinitely long canal—a wave of the same height as is found at the same instant, the sum will be equal to twice the velocity which the wave would have generated at that instant in the hypothetical canal.

Since the second members of Equations (58) and (60) are constant for any point at a particular instant, it shows that any decrease in the height of water above or below the theoretical height for the long canal must be accompanied by an increase in velocity, or *vice versa,* and that the total amount of energy manifested is the same in any case.

For the compound or resultant wave there is no approximately constant value for the ratio between h and v, as in the case of the simple wave of translation. Failure to comprehend this departure of the compound wave from the laws pertaining to the simple wave has heretofore made the computation of the tidal characteristics of any given point in a tidal canal quite unsatisfactory. It is now proposed to show that a satisfactory agreement between observed tidal phenomena and the computed values of such phenomena can be reached, and that the computation in any case can be made sufficiently close to enable all tidal phenomena in canals of fairly uniform size to be predicted.

APPLICATION OF THE THEORY TO THE SUEZ CANAL

That section of the Suez Canal between the Red Sea and the Bitter Lakes is an example of the type of canal under consideration. It is 26 km. (16 miles) long, and has an average semi-amplitude of tide of 2.24 ft. at the Suez entrance. The amplitude gradually diminishes until at the Bitter Lakes all tidal variation disappears. The Bitter Lakes have an area of about 48 500 acres, which is large enough to receive the tidal flow without appreciable change in level.

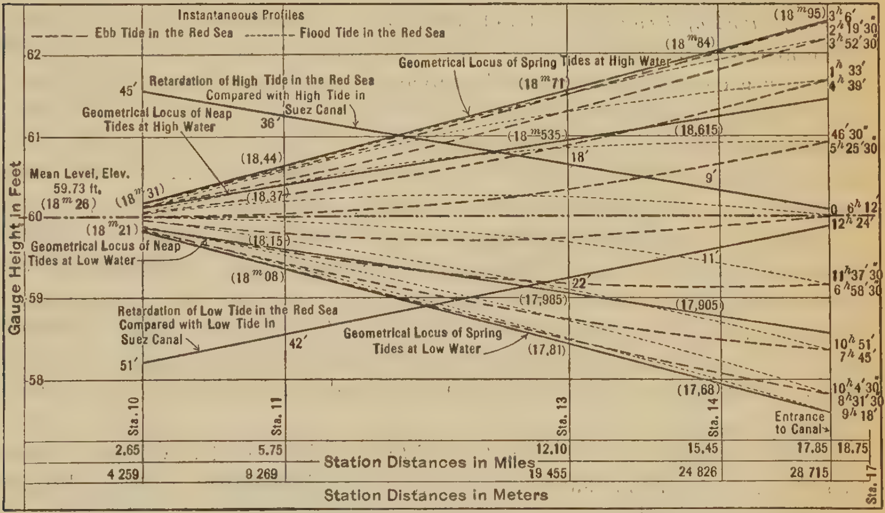

FIG. 9.—GRAPHICAL REPRESENTATION OF THE MEAN INSTANTANEOUS PROFILES OF THE SUEZ CANAL BETWEEN THE RED SEA AND THE BITTER LAKES: THIRD QUARTER OF 1898.

Lévy tested his theory[8] by comparison with observations on the Suez Canal. He found that while it could account for the observed heights of the tide, it could not account for the observed velocities, particularly those at the outlet of the canal into the Bitter Lakes. This canal was also the subject of rather complete tidal observations, some of which are given by Bourdelles[15] in an idealized graphical representation of the mean instantaneous profiles of the canal between the Red Sea and the Bitter Lakes (Fig. 9).

---

[15] "Etude sur le Régime de la Marée dans le Canal de Suez," *Annales des Ponts et Chaussees*, 1898, 3^{me} trimestre.

In his memoir, Bourdelles directed attention to the failure of any previous theory to account for the high velocities at the outlet where all existing theories called for the disappearance of the velocity when the height of the wave vanished. He found a satisfactory agreement with theory for velocity near the Suez end, but the discrepancies increased toward the lake end. To explain this, he was forced to resort to the theory that the excess velocity over that caused by the height of wave must be due to a flow under the influence of the surface slope of the wave, but no proof of such flow could be adduced.

Under the reflected wave theory, the computed velocities agree quite well with the observed velocities, and the computed heights are almost identical with those given by Bourdelles. Unfortunately, Bourdelles gives very little information as to velocities, simply naming the maximum velocities observed at certain points without giving the amplitude of the tide at the Suez Station during the tidal period which gave rise to those velocities. It is assumed that the velocities which he does give were generated during an average tide such as he indicates upon his profiles, and the comparisons are based upon that assumption.

Coefficient of Friction.—The channel of the Suez Canal is not of uniform width at the point where it enters the Bitter Lakes; it widens gradually. This results in a corresponding gradual decrease in velocity, which makes it somewhat difficult to obtain the frictional coefficient by the use of Equation (56). An observed value of V_0 at the mouth where all tidal variation ceases would not represent the true value of H_1 and, consequently, of F. If data were available as to the exact amount of widening that occurs at this point an approximate value of V_0 could be obtained. Bourdelles reports an observed velocity of 1.64 ft. per sec. (0.50 m. per sec.) at the outlet. Assuming that the actual area of cross-section here has widened to, say, 500 sq. m., as opposed to 304 sq. m. given for the standard section $A_1 V_1 = A_0 V_0 = 500 \times 0.50 = 304 \times V_0$, or $V_0 = 0.82$ m. per sec. (2.69 ft. per sec.), which gives a value of 0.31 m. (1.33 ft.) for H_1 in Equation (56) and a value of 2.655 for F from Equation (26).

A more satisfactory determination of the frictional coefficient can be made by going back into the channel to a point where the uniform width and depth are still maintained. For example, at Station 11 in Fig. 9, the tide and velocity of the current are both given. In this case it is necessary to proceed in a somewhat different manner, since the heights of the direct and reflected waves will not be equal at this point like they are at the outlet. It is now necessary to make use of Equation (57). In that equation, substitute t_m for t; v is not the maximum velocity in this case, but the velocity at high water, observed simultaneously with h_m.

At the time of the observations, the canal was 22 m. (72 ft.) wide on the bottom, with side slopes of 1 on 2. The depth was 8 m. (26 ft.) below the datum plane of mean tide, which was at an elevation of +18.26 m. (59.73 ft.). The following, therefore, are the basic data on which the computations are based:

	Metric units.	English units.
Area of cross-section at mean sea level, in square meters and square feet...........	304	3 272
Width of canal at mean sea level, in meters and feet..............................	54	177
Wetted perimeter, in meters and feet........	57.77	189.54
Semi-amplitude of the tide at Suez, in meters and feet..............................	0.69	2.26
Length of canal, in kilometers and miles.....	26	1.6
Reduced depth, $\frac{304}{54}$, in meters and feet.......	5.63	18.47

For Chalouf, Bourdelles gives the following data: Height, 0.18 m. (0.59 ft.), and velocity, 0.80 m. per sec. (2.62 ft. per sec.).

As t_1 is the time required for the wave of translation to travel to the point of observation under the assumption of an infinitely long canal,

$$t_1 = \frac{x}{c} = \frac{x}{\sqrt{g\,(D + h)}} = \frac{19\,446}{\sqrt{(5.63 + 0.18)\,(98.06)}} = 2\,576 \text{ sec.} = 43 \text{ min.}$$

The other term, t_m, is the time at which high water occurred at the point of observation, which is given by Bourdelles as occurring 36 min. later than at Suez, or about 30 min. later than at the canal entrance, making $t_m - t_1 = (-43 + 30) = -13$ min., which gives the value, $2\,\pi \left(\frac{t_m - t_1}{T}\right) = 6° \, 17'$.

Substituting these values in Equation (57), $0.18 + 0.80 \sqrt{\frac{5.63 + 0.18}{9.806 +}}$

$$= 2\,H_1 \cos 6° \, 17'; \text{ whence, } H_1 = \frac{0.18 + 0.80 \sqrt{\frac{5.63 + 0.18}{9.806 +}}}{2 \cos 6° \, 17'} = 0.4023.$$

Substituting this value in Equation (26), in which, $H_0 = 0.69$, $x = 19\,446$, and $D = 5.63$; then, $8.2439 = \frac{F\,p\,x}{2\,\rho\,l\,\sqrt{g}}$; and $F = 2.4816$.

The value of F as given by Bonnet for the Scheldt River is 2.4802. The close agreement between these values is noteworthy, but is probably accidental.

Computation of Tidal Curves.—Using this value of F, the computations in Tables 1 and 2 may be made. These tables give the values of H and of t for various selected stations which are the points of observation for the data upon which Bourdelles' curves are based. In Table 1 the value of $\frac{F\,p}{2\,\rho\,l\,\sqrt{g}}$ equals 0.000423935. The data contained make it possible to write the following general equations of the tide for those stations; for example, at Station 3889 (Table 1), the equation for the positive wave is:

$$h = + 0.622 \cos 2\,\pi \left(\frac{t - 496}{T}\right) - 0.159 \cos 2\,\pi \left(\frac{t - 6\,298}{T}\right)$$
$$+ 0.123 \cos 2\,\pi \left(\frac{t - 7\,290}{T}\right) - 0.01 \cos 2\,\pi \left(\frac{t - 13\,092}{T}\right) \ldots\ldots \quad (61)$$

TABLE 1.—COMPUTATIONS FOR DETERMINING THE GENERAL EQUATIONS FOR POSITIVE WAVES, THE SUEZ CANAL.

---

* Δx is the distance between stations corresponding to selected values of H.

† These figures are the means of those in the preceding column.

‡ As this wave is very small, it is assumed to become extinguished progressively in this reflection .

and for the negative wave (Table 2):

$$h = -0.595 \cos 2\pi \left(\frac{t - 554}{T}\right) + 0.14 \cos 2\pi \left(\frac{t - 6\,648}{T}\right)$$
$$-0.109 \cos 2\pi \left(\frac{t - 7\,756}{T}\right) + 0.02 \cos 2\pi \left(\frac{t - 13\,850}{T}\right) \ldots\ldots (62)$$

At Station 9260, the equation for the positive wave is:

$$h = +0.537 \cos 2\pi \left(\frac{t - 1\,188}{T}\right) - 0.190 \cos 2\pi \left(\frac{t - 5\,606}{T}\right)$$
$$+0.105 \cos 2\pi \left(\frac{t - 7\,982}{T}\right) - 0.02 \cos 2\pi \left(\frac{t - 12\,400}{T}\right) \ldots\ldots (63)$$

and for the negative wave:

$$h = -0.487 \cos 2\pi \left(\frac{t - 1\,310}{T}\right) + 0.166 \cos 2\pi \left(\frac{t - 5\,892}{T}\right)$$
$$-0.092 \cos 2\pi \left(\frac{t - 8\,512}{T}\right) + 0.02 \cos 2\pi \left(\frac{t - 13\,094}{T}\right) \ldots\ldots (64)$$

These general equations may then be transformed—by the methods described for Equation (47)—into the simpler forms given below. Each one gives, directly, the maximum value of h, and the time required for the resultant wave to be propagated from the entrance to the point being considered, that is, the time of occurrence of high water.

The transformed equations are as follows: For Station 3889, the positive wave is,

$$h = +0.5864 \cos 2\pi \left(\frac{t - 190}{T}\right) \ldots\ldots\ldots\ldots\ldots\ldots (65)$$

and the negative wave is,

$$h = -0.5648 \cos 2\pi \left(\frac{t - 263}{T}\right) \ldots\ldots\ldots\ldots\ldots\ldots (66)$$

At Station 9260, the positive wave is:

$$h = +0.4456 \cos 2\pi \left(\frac{t - 483}{T}\right) \ldots\ldots\ldots\ldots\ldots\ldots (67)$$

the negative wave:

$$h = -0.4073 \cos 2\pi \left(\frac{t - 556}{T}\right) \ldots\ldots\ldots\ldots\ldots\ldots (68)$$

By giving proper values to t, instantaneous profiles may be constructed as shown in Fig. 10. Similar equations for velocity at the same stations may be found from the Equations (61) to (64) as explained for Equation (49), and from those equations instantaneous velocity curves may be plotted as shown in Fig. 11.

Comparing Figs. 9 and 10, it will be noted that the instantaneous profiles are very similar and that all the discrepancies are of a minor character.

Heights.—Bourdelles' curves are based on a complete symmetry between the positive and negative wave curves.[15] Under any known theory of wave propagation complete symmetry can exist only when the height of the wave is negligible with respect to the depth, which is not the case in the present instance. It is

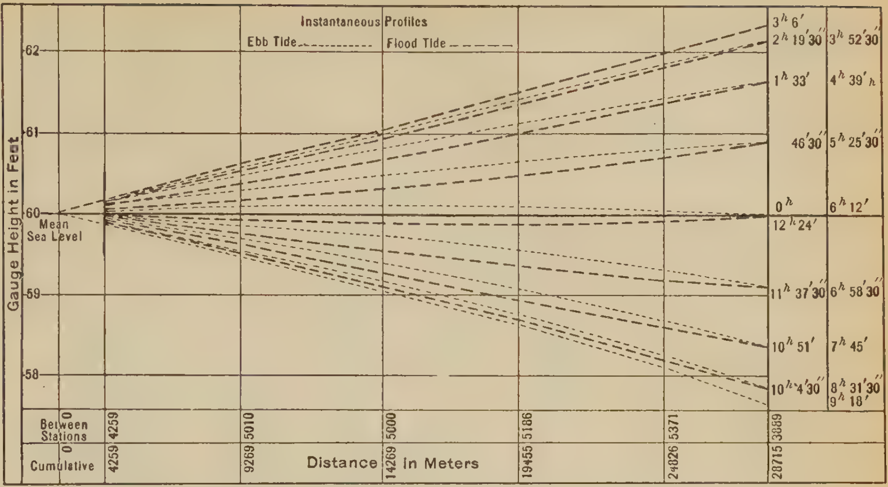

FIG. 10.—INSTANTANEOUS PROFILES COMPUTED FOR SUEZ CANAL.

the practice of the United States Coast and Geodetic Survey to allow for lack of symmetry between positive and negative waves in making tidal predictions by introducing a "shallow-water" component into the computations.[16] The new theory automatically allows for the shallow-water component when a separate computation is made for the negative wave.

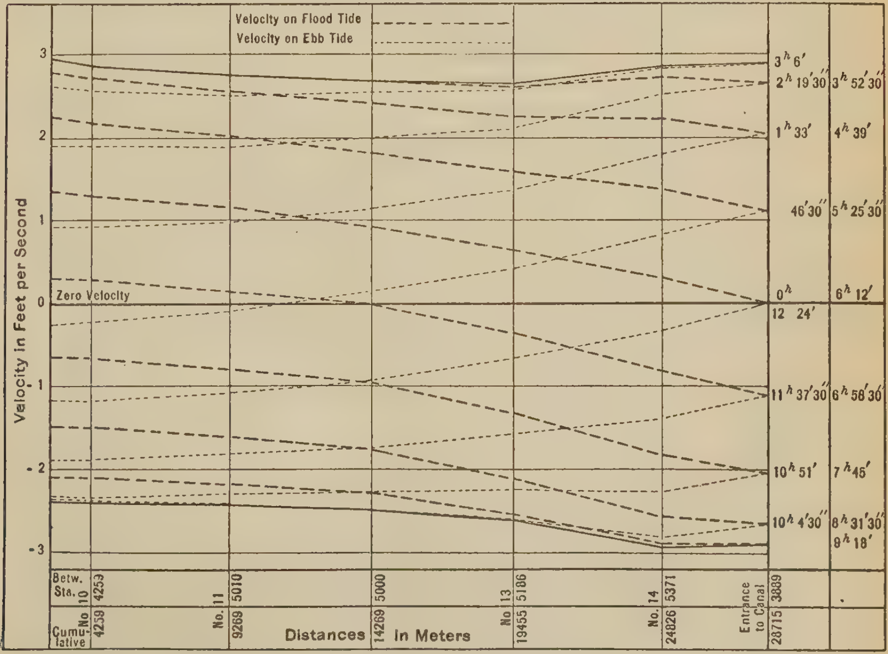

FIG. 11.—INSTANTANEOUS VELOCITY CURVES CORRESPONDING TO FIG. 10.

---

Velocities.—It is in the matter of velocities that the new theory shows its superiority over the previous theories. Both Lévy and Bourdelles were compelled to confess the failure of any theory of tidal propagation to explain the discrepancies noted between observed and computed velocities. These discrepancies were small at the Suez end of the canal, but they increased in magnitude until at the end at the Bitter Lakes there was complete disagreement. The velocities at all points in the canal, as computed by the new theory, are in satisfactory agreement with those observed, and it fully explains the reasons for the high velocity found at the outlet into the lakes. (See Fig. 11.) Table 4 shows a comparison between observed and computed velocities.

TABLE 4.—COMPARISON BETWEEN COMPUTED AND OBSERVED MAXIMUM TIDAL VELOCITIES AT STATED STATIONS ON THE SUEZ CANAL.

STATION.	Stage of tide.	MAXIMUM TIDAL VELOCITIES, IN METERS PER SECOND.		
Distance from Red Sea, in meters.		Bourdelles.	Levy.	Present theory.
0	High water	0.90	0.28	0.860
0	Low water	0.80	....	0.71

	Low water	0.80	....	0.72
24 456	Low water	....	....	0.858
26 000	Low water	0.50	....	0.880*

* If allowance is made for the widening of the canal to 500 m. at this station, this figure becomes 0.54 m. per sec.

Retardations.—Bourdelles reports the speed of the tidal wave as being practically constant, and hence the retardation of the tide at any point is shown as being substantially proportional to its distance from the Suez end. He admits some uncertainty in regard to the determination of the times of high and low water "by reason of the imperfections in the mode of observation used, which consisted only in readings upon graduated scales".[15] The theory of the interference of waves as explained herein under the heading, "Theory of the Interference of Two Opposed Waves", requires that the speed of the resultant wave shall be variable, and not constant, although it will be constant for a distance of one wave length. The retardations as computed by the new theory are not markedly different from those given by Bourdelles; yet they conform to theoretical requirements (see Table 5).

Inland Waterway from Pamlico Sound to Beaufort Inlet, N. C.—This is an artificial canal connecting the waters named, which was constructed by the United States about 1910. In 1911, some observations[17] were made of the action of the tidal currents in this canal to determine whether there were prospects of the currents attaining velocities such as to hinder navigation, and to require the installation of guard locks.

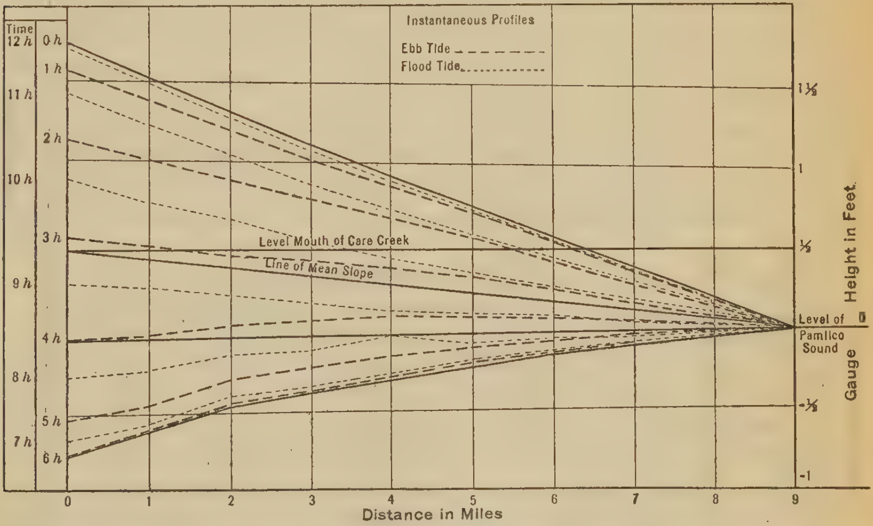

FIG. 12.—INSTANTANEOUS PROFILES AS COMPUTED FOR THE WATERWAY FROM BEAUFORT INLET TO PAMLICO SOUND, NORTH CAROLINA.

---

[17] *Professional Memoirs*, Corps of Engrs., U. S. A., 1912, vol. 4, p. 216.

Briefly, this waterway comprises three sections: The tidal stream known as Core Creek at the southern end; the connecting artificial canal; and the non-tidal Adams Creek at the northern end. The dimensions of the canal were 90 ft. wide on the bottom, with side slopes of 1 on 2, and 10 ft. deep referred to mean low water in Beaufort Harbor, near-by. The mean level of Adams Creek was 1.4 ft. referred to the same datum. The portion of the canal herein considered is about 8½ miles long.

The mean amplitude of the tide was found to be about 2.6 ft. at the mouth of Core Creek; thence it gradually decreased until all tidal variation of level practically disappeared at Hooker's Landing at the head of Adams Creek. Conversely, tidal velocities were mildest at the mouth of Core Creek, and greatest at Hooker's Landing. Some change of level was found at Hooker's Landing, but it was due entirely to wind effects on the level of Pamlico Sound and River into which Adams Creek empties. Curves of instantaneous heights and velocities for this canal have been computed under the proposed theory, as shown in Figs. 12 and 13, respectively. These may be compared with similar curves of observed data prepared by the Corps of Engineers, U. S. Army.

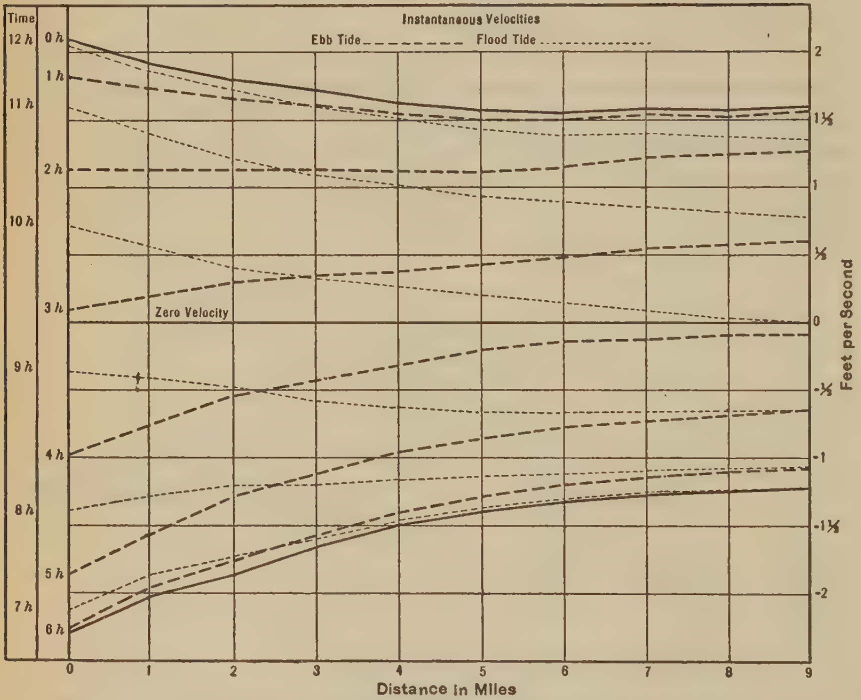

FIG. 13.—INSTANTANEOUS VELOCITIES AS COMPUTED FOR THE WATERWAY FROM BEAUFORT INLET TO PAMLICO SOUND, NORTH CAROLINA.

It will be noted that the mean level at the mouth of Core Creek is higher than that at Hooker's Landing, thus increasing the tidal velocities by a permanent set of the current northward due to this slope. This difference in level has been taken into account in computing the curves in Figs. 12 and 13.

The Rehoboth Canal.—It is now proposed to test the foregoing theory in a more complex example. The Inland Waterway between Rehoboth Bay and Delaware Bay, Delaware, is a tidal canal situated in the southeasterly portion of Sussex County, Delaware. It extends, for a distance of 12 miles, northward from Rehoboth Bay, through the highlands west of the Town of Rehoboth; thence through the marshes back of Cape Henlopen to Lewes River, a small tidal creek; and thence it follows this creek to Broadkill River at a point near the mouth of that stream, through which it empties into Delaware Bay about 5 miles from Cape Henlopen.

This canal was constructed by the United States about 1913, under a project which provides for a waterway 6 ft. deep at mean low water, 50 ft. wide through Lewes River and the marshes, and 40 ft. wide where it passes through deeper cutting.

Rehoboth Bay and Indian River Bay are two "drowned" valleys which formerly communicated with the Atlantic Ocean through an inlet. This inlet has closed and the two bays are completely separated from the ocean except by the Rehoboth Canal on the north and the Assowoman Canal on the south. The two bays, which are of about equal size, and which have a combined area of about 20 sq. miles, are partly separated from each other by a series of islands known as Burton's Islands, the connecting channels between the islands being locally known as the "Ditches". Those portions of the bays adjacent to the littoral cordon are quite shoal, but the average depth of the two bays elsewhere is about 6 ft.

The Assowoman Canal is a small artificial cut, originally intended to be 6 ft. deep and from 40 to 50 ft. wide. It connects Chincoteague Bay, Virginia, with Indian River Bay by way of Sinepuxent Bay, Maryland.

The surface level of Rehoboth and Indian River Bays is now quite constant; it is affected very little by anything but the wind. Tidal flow reaches the bays through the Rehoboth Canal, but has no apparent effect on their level. The current through the Assowoman Canal is not tidal, although the normal outflowing current may occasionally be reversed in direction by the wind.

The canal is naturally divided into two parts differing in physical characteristics. The northerly portion, 23 663 ft. long, has an average width of water surface at mean sea level of 100 ft., and an average sectional area of 900 sq. ft., making the reduced depth 9 ft. This portion of the canal comprises the bed of the former Lewes Creek, a stream heading up near Cape Henlopen. The canal bed narrows to a width of 80 ft. at Lewes, but maintains about the same depth. From the end of this section 3 000 ft. east of Lewes an artificial cut extends, for 33 404 ft., to the jetties in Rehoboth Bay terminating the canal. This cut has an average width on the surface of 78 ft. and an average cross-section at mean tide of 548 sq. ft., or a reduced depth of 7 ft.

In the artificial cut, the propagation is regular, and in accordance with theory. The height of the wave gradually decreases until it disappears in Rehoboth Bay, while the tidal velocities retain higher values than a direct proportion to the height of tide. The surface heights and velocities conform to the requirements of the theory of a resultant wave caused by the superposition on a primary wave of a reflected negative wave from the bay.

In view of the difference in depth and area of the two sections of the canal as just mentioned, the tidal wave cannot be expected to be propagated through the entire length of the canal as simply as it would if both depth and cross-sections were constant for the entire distance. At the point of junction of the artificial cut with the old creek bed, a portion of the wave will continue on to the head of the old creek where a reflection of the wave back upon itself must be expected. This reflected wave, combining with the original wave, may be expected to cause higher levels and smaller velocities in that portion of the canal near Lewes than would have occurred normally. Furthermore, the constriction of the channel at Lewes must generate a reflected positive wave, and the division of the wave at the junction point must generate a reflected negative wave. These reflected waves may be expected to have a more pronounced effect near Lewes than near Broadkill, and to exert that effect at an earlier instant. The writer's observations amply confirm this expectation. Fig. 14 shows curves of instantaneous heights as given by hourly gauge readings made in August, 1925. These curves reveal clearly the large gauge heights and the advanced phases of the tide at Lewes resulting from this change of section.

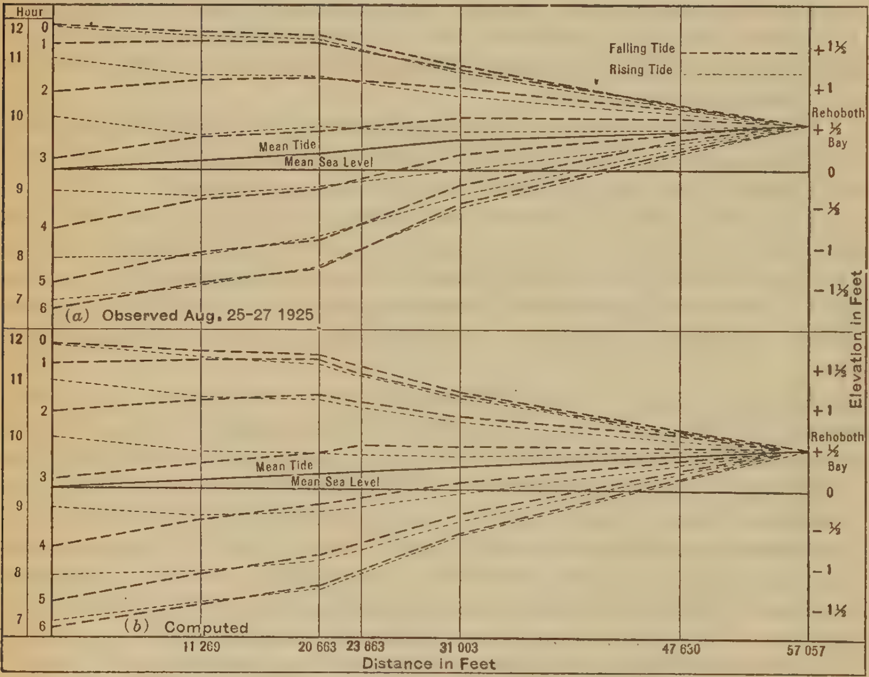

FIG. 14.—INSTANTANEOUS PROFILES IN THE LEWES-REHOBOTH CANAL, DELAWARE.

To find the resultant wave in this portion of the canal, first compute the direct wave, the positive reflected wave coming from the constriction at Lewes, the positive reflected wave from the head of the old creek, and the negative reflected wave from the junction with the artificial cut. A summation of these waves will give the tidal characteristics of the Lewes River section. The remaining portion of the canal can be treated as being affected solely by the direct positive and the reflected negative wave.

Computation of Tidal Curves.—The tidal characteristics of the remainder of the canal may be determined by using the tidal curve at the junction as a generatrix of the tide between this point and the jetties.

Observations made in August, 1925, disclosed a maximum mean velocity of 1.41 ft. per sec. at the jetties, and a tidal amplitude of 2.8 ft. at the junction. Therefore, $H_1 = \frac{1}{2} \times 1.41 \sqrt{\frac{7}{32.17}} = 0.33$ ft., and the following values may then be determined for substitution in Equation (26): $H_0 = 1.4$ ft.; $x =$ 33 404 ft.; $D = 7$ ft.; $H_1 = 0.33$ ft.; $l = 78$ ft.; and $p = 83.4$ ft.

Making these substitutions, the constant, $\frac{F p}{2 \rho l \sqrt{g}}$, is found to have the value, 0.00087877, from which, F is found to have the value, 0.5883. With this value of F in Equation (26), the height, H, at any point, x, along the canal may be found for both direct and reflected waves. Since the values of l and p are, respectively, 100 and 105 ft. for the Lewes River Section, the corresponding value of $\frac{F p}{2 \rho l \sqrt{g}}$ will be 0.0008629.

The heights for each wave at selected points, as well as the times of propagation, may be computed as illustrated in Tables 1 and 2, and from these the phase angles are found. The general equations are then written for each point in a manner similar to the use made of Tables 1 and 2.

Fig. 13 is a graphical comparison between observed and computed instantaneous tidal curves.

Mean Level.—Attention has been called to the lack of symmetry between the geometric loci of high and low waters. If "mean canal level" is defined as a point midway between mean high water and mean low water at any point, it is quite evident that the locus of mean canal level so defined will not coincide with mean sea level which is the plane of reference. Tangent to mean sea level at the mouth, the locus of mean canal level will gradually ascend, and will be higher than mean sea level at the outlet in the reservoir, provided the reservoir can adapt itself to this condition. If not of unlimited capacity, it will so adapt itself in course of time.

If the reservoir surface should be below mean canal level at the outlet, the direct negative wave cannot return to the sea all the water brought in by the positive wave and an excess volume will remain in the reservoir; this excess must eventually bring it to the critical level. If the reservoir surface is above the mean canal level, the negative wave will return more water to the sea than was brought in by the positive wave, and eventually this must reduce the level to the proper elevation.

If the reservoir capacity is too great for such an adjustment to become effected, then the locus of mean canal level will incline downward from a point of maximum height and will become tangent to the reservoir level at the outlet.

It takes this form in any case during the periods of adjustment previously mentioned. Such a condition has been noted in connection with Adams Creek.

A fresh-water discharge into a comparatively small bay, such as those under consideration, will tend to raise the mean level above mean sea level.

The mean level of Rehoboth Bay is 0.55 ft. higher than mean sea level and the mean level of the canal rises gradually from one end to the other. This difference of level is to be attributed to the two causes just mentioned. Sufficient data do not exist upon which to determine the portions of this difference attributable to each cause. Measurements made at the jetties show a flood discharge of 11 070 090 cu. ft. per tide, and an ebb discharge of 12 230 330 cu. ft. per tide, a difference of 1 160 240 cu. ft. per tide, which represents a part of the fresh-water drainage into the basin. Proper corrections must be made to all computed values of tidal variation and tidal velocities in order to allow for the canal slope and fresh-water discharge. These corrections are made on the curves of instantaneous heights and velocities.

Comparison of Computed and Observed Data.—A series of tidal observations was taken upon the Rehoboth Canal at six selected stations during August, 1925, and gaugings were made at two stations near the respective ends of the canal. The height of the tide was read every 15 min. on a staff gauge at each station, the zero of which was established at the level of mean low water for Delaware Breakwater. These readings were used to determine mean sea level, mean range of tide, and mean high and mean low waters at each station.

Reduction of Observations.—The following method was used to check these determinations, and to give in addition the time of propagation of the tide from station to station.

If the time of making any reading upon a staff gauge is observed, and the height of the reading above mean sea level is known, the results of this observation may be used to write the equation,

$$h = H \sin 2\pi \left(\frac{t + c}{T}\right) \ldots\ldots\ldots\ldots\ldots\ldots (69)$$

in which, h and t are the observed height and time, respectively; H is the local half amplitude of the tide; and c is the time before the instant, $t = 0$, when the tide was at mean sea level; that is, when $t + c$ was equal to 0. It is clear that an independent equation of this form can be written for each observation, and, consequently, as many observation equations may be formed as are desirable for each tide, and they may be reduced by the methods of least squares to find the mean values of H and c.

If a series of observations are taken at several different stations, all reckoned from the same instant when $t = 0$, a value of c may be found for each point of observation, and the difference between the values of c for any two given points will be the time required for the tidal wave to be propagated between those stations.

In case the elevation of mean sea level is not known, the staff reading may be used directly, without a reduction, to determine the value of h.

Let R be the staff reading, the zero of the gauge being set at any desired elevation. Then, if e represents the elevation of mean sea level on the staff, $h = R - e$, and the observation equation may be written,

$$R = e + H \sin 2\pi \left(\frac{t + c}{T}\right) \ldots\ldots\ldots\ldots\ldots\ldots \text{(70)}$$

in which, e, H, and c are unknown.

Expanding,

$$R = e + \sin 2\pi \frac{t}{T} H \cos 2\pi \frac{c}{T} + \cos 2\pi \frac{t}{T} H \sin 2\pi \frac{c}{T} \ldots \text{(71)}$$

If n observations are made during any tide, n independent observation equations may be written, from which normal equations for each unknown quantity may be formed by the usual methods of least squares. These equations will be in the form,

$$\Sigma R = n e + H \cos 2\pi \frac{c}{T} \Sigma \sin 2\pi \frac{t}{T} + H \sin 2\pi \frac{c}{T} \Sigma \cos 2\pi \frac{t}{T} . \text{(72)}$$

$$\Sigma R \sin 2\pi \frac{t}{T} = e \Sigma \sin 2\pi \frac{t}{T} + H \cos 2\pi \frac{c}{T} \Sigma \sin^2 2\pi \frac{t}{T}$$
$$+ H \sin 2\pi \frac{c}{T} \Sigma \sin 2\pi \frac{t}{T} \cos 2\pi \frac{t}{T} \ldots\ldots\ldots\ldots \text{(73)}$$

$$\Sigma R \cos 2\pi \frac{t}{T} = e \Sigma \cos 2\pi \frac{t}{T} + H \cos 2\pi \frac{t}{T} \Sigma \sin 2\pi \frac{t}{T} \cos 2\pi \frac{t}{T}$$
$$+ H \sin 2\pi \frac{c}{T} \Sigma \cos^2 2\pi \frac{t}{T} \ldots\ldots\ldots\ldots\ldots\ldots \text{(74)}$$

In the observations at the Rehoboth Canal, hourly readings were used for this computation, and n was made 14 so as to embrace one complete tide in one set of equations. In this case, Equations (72), (73), and (74) become reduced to the following forms:

$$37.4 = 14\,e + 0.3267\,H \cos 2\pi \frac{c}{T} + 1.5376\,H \sin 2\pi \frac{c}{T} \ldots\ldots \text{(75)}$$

$$11.1686 = 0.3267\,e + 6.2924\,H \cos 2\pi \frac{c}{T} + 0.2135\,H \sin 2\pi \frac{c}{T} \ldots \text{(76)}$$

$$10.3442 = 1.5376\,e + 0.2135\,H \cos 2\pi \frac{c}{T} + 7.7076\,H \sin 2\pi \frac{c}{T} \ldots \text{(77)}$$

The left-hand members of Equations (75), (76), and (77) are the only ones that change for different stations, as t is counted for each station in all cases from the same instant. This makes the solution of a series of equations for observations at different points an easy process.

Table 6 gives the results of the solution of five sets of simultaneous observations at five points on the canal.

The values of c are given in Table 7, from which the time of propagation of the tide from the Broadkill Station to each of the others is obtained.

The differences are as listed in Table 8.

It was noted during the period of observations that the canal surface was quite sensitive to the wind, and this fact is reflected in Table 8, but it is quite probable that that effect has been partly eliminated in the averages, and that they may be accepted as representative values. Since the computed times of propagation of the wave do not differ from the mean observed time by amounts greater than the mean error of the observed values, they may be accepted as confirmatory to the theory.

Canal Communicating with a Tidal Reservoir of Limited Capacity

It is now proposed to consider the case of the flow in a tidal canal having no proper tide of its own, but which connects a tidal sea with a basin of limited capacity such that, under the influence of the tide transmitted to it through the canal, its own surface undergoes periodic oscillations of level.

To explain the phenomena observed during the propagation of the tide in the type of canal now considered, assume as before that the wave propagated in the canal is assimilated to a series of small waves of translation. Consequently, it is formed during the flood by a series of successive intumescences or influxes of small height and by a similar series of depressions or refluxes during the ebb. These influxes and refluxes are propagated with the speeds and velocities determined by Equations (1) and (13), already given, conformably with the theory of waves of translation.

Assuming the sea, the canal, and the basin to be in equilibrium and at the same mean level, and that the first influx is then introduced, its action will be analogous to that of a canal communicating with a limitless reservoir except that the volume of the intumescence now has a finite relation to the volume of the basin, and will suffice, when introduced therein, to raise its level a certain amount. The rise of level will oppose the continued introduction of the intumescence into the basin, but this opposition will not be sufficient to counteract it completely until the volume of the intumescence poured into the basin shall equal in quantity the area of the basin multiplied by the height of the intumescence. When that occurs, the basin will be emitting into the canal in the direction of the sea, an opposed intumescence of equal height, the velocity due to which will completely annul that due to the first intumescence so that all flow will cease. Between the time of first arrival of the original intumescence at the outlet into the basin and the time when the basin intumescence exactly equals the original, the magnitude of the opposing basin intumescence will be increasing from zero to its final magnitude. Consequently, the effective magnitude of the original intumescence as an instrument for filling the basin to its own height will gradually diminish and will disappear when the basin is filled to that height.

In the case of an infinitely large reservoir as previously described, it was shown that as the intumescence was unable to raise the basin level, it was compelled to disappear in the basin through a lowering of its height and an increase of its velocity, resulting in a reflected depression of equal amplitude. Similarly, in the present instance, the intumescence must disappear in the basin, but the surface level of the basin will be rising, and, consequently, the reflected depression will not be equal to the original intumescence, but will be equal only to the difference between the height of the intumescence and that of the basin surface at the same instant.

If the height of the intumescence as transmitted in the infinitely long canal and reduced by friction is h_l on its arrival at the basin, and if the height of the basin level at the same moment is h_b, the disappearance of the intumescence in the basin requires that any difference between h_l and h_b give rise to a reflected depression of height equal to $-(h_l - h_b)$, which is equivalent to considering a depression and an intumescence with respective heights equal to $-h_l$ and $+h_b$. The depression with a height equal to $-h_l$ is clearly the reflected depression corresponding to h_l already mentioned in the case of an infinitely large reservoir, and h_b is a new intumescence emitted by the basin, due to the rising of its level.

Similarly, a second intumescence propagating itself on the first one will raise the basin surface again to a point of equilibrium, thus giving rise to a similar series of phenomena, etc., for each influx.

As long as the successive influxes propagated into the canal and thence into the basin are greater in volume than the opposed fluxes emitted by the basin, the tide will be in flood, and the surface of the basin will continue to rise.

When the influxes shall have ceased to be further propagated, at high water, and the refluxes shall have begun to be propagated, these refluxes will add their velocity to that of the opposed fluxes from the basin. When the time arrives at which this sum is exactly equal to the combined velocity of the influxes, or when the total height of all intumescences is equal to the sum of the heights of all intumescences emitted from the basin, the basin level will cease to rise, and the velocity of inflow will be zero. Thenceforward, as the refluxes gain over the influxes, the surface of the basin will fall.

Manifestly, a similar reasoning on the refluxes of the negative wave would indicate an emptying of the basin until the influxes of a rising tide should cause a cessation of the emptying, and the resumption of a filling.

Previously, in discussing the properties of the wave of translation propagated in an infinitely long canal, the result of limiting the length by the introduction of an infinitely large reservoir was considered, and it was found that the result was to generate an opposed negative wave of magnitude equal to that of the original positive wave. The effect of limiting the length of such a canal by the introduction of a like reservoir, of limited capacity, will be similar, but with the added difference of causing the generation of a third wave—that emitted from the basin—which will be positive for a positive generatrix.

Therefore, the canal connecting the tidal sea with a basin of limited capacity will always have within it at least three simple waves of translation, and the actual heights and velocities at any point in it will be the resultant of those due to these three waves. The first will be the simple wave of translation generated by the tide in the sea, which will be propagated with proper friction losses as already explained for an infinitely long canal. The second wave will be the reflected negative wave corresponding to the first one exactly as previously explained. The third wave will be that emitted by the basin, positive for a positive tide and negative for a negative tide, and of a magnitude at the canal outlet in the basin that will be exactly equal to the height of the basin level, but subject to the usual friction losses while being propagated in the canal itself.

Let the following additional notations be assumed:

H_b = the semi-amplitude of the basin tide.
t_b = the time of high water of the basin tide.
V_b = the velocity due to the height of wave, H_b.

The following equations may now be written for the tidal variation at the outlet into the basin,

$$h = H_1 \cos 2\pi \left(\frac{t - t_1}{T}\right) - H_2 \cos 2\pi \left(\frac{t - t_2}{T}\right) + H_b \cos 2\pi \left(\frac{t - t_b}{T}\right). \quad (78)$$

When $t = t_b$, then $h = H_b$; hence,

$$H_b = H_1 \cos 2\pi \left(\frac{t_b - t_1}{T}\right) - H_2 \cos 2\pi \left(\frac{t_b - t_2}{T}\right) + H_b \ldots\ldots (79)$$

Therefore,

$$H_1 \cos 2\pi \left(\frac{t_b - t_1}{T}\right) - H_2 \cos 2\pi \left(\frac{t_b - t_2}{T}\right) = 0 \ldots\ldots\ldots\ldots (80)$$

Since the direct wave and the reflected wave must have the same phase at the outlet into the basin, $t_1 = t_2$; hence, $H_1 = H_2$, and Equation (78) becomes

$$h = H_b \cos 2\pi \left(\frac{t - t_b}{T}\right) \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (81)$$

The values of H_b and t_b will depend upon two factors, the first of which is the amplitude of the original wave of translation, and the second, the area of the basin. The first of these factors determines for a specific case the volume of the wave capable of being transmitted into the basin and available for filling it. The second determines the depth to which the filling may proceed, and, therefore, the proportion of the total volume of the wave of translation which is used for that purpose.

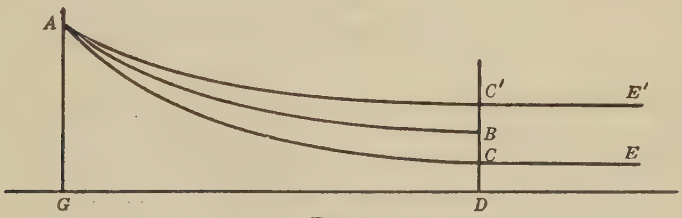

FIG. 15.

In Fig. 15, let $A B$ be the geometric locus of H as computed for the distance, $G D$, in an infinitely long canal having a semi-amplitude, $G A$, at G. The height, $D B$, will be the computed semi-amplitude of the wave, $A G$, as reduced by friction. Let $D B$ be the point at which the canal enters a basin the surface of which is represented by $C E$, and let $D C$ be the semi-amplitude of the surface variation of the level in the basin. Let it be assumed, also, for simplicity, that the area M, of the basin, is constant for all heights of the tide, so that its cubical contents above low-water level at any moment may be given by the expression, $M \times H_b \left(1 + \cos 2\pi \left(\frac{t - t_b}{T}\right)\right)$.

The heights, $D B$ and $D C$, will seldom be equal. Since the actual height of water in the canal will automatically adjust itself to that of the basin, the theoretical geometric locus of H will seldom coincide with the actual locus. If the basin rises only to $C E$, the geometric locus of high water in the canal will be $A C$ instead of $A B$. This means that the basin is of such large capacity that it receives not only the volume of the wave, $D B$, but also the volume equivalent to a wave the height of which is $C B$. If the basin is smaller, $D C$ may become larger than $B D$ as, for example, $D C'$. This condition would denote a basin with an area too small to afford a capacity to receive the entire volume of the wave, $D B$, and a surplus would be stored in the canal equal in volume to that of a wave with a height, $B C'$.

As shown in developing Equation (50), the velocity equation corresponding to Equation (78) may be written,

$$v = V_1 \cos 2\pi \left(\frac{t - t_1}{T}\right) + V_2 \cos 2\pi \left(\frac{t - t_2}{T}\right) - V_b \cos 2\pi \left(\frac{t - t_b}{T}\right) . \quad (82)$$

and,

$$v = 2 V_1 \cos 2\pi \left(\frac{t - t_1}{T}\right) - V_b \cos 2\pi \left(\frac{t - t_b}{T}\right) \ldots\ldots\ldots\ldots (83)$$

It has already been seen that when $t = t_b$, $v = 0$, hence,

$$0 = 2 V_1 \cos 2\pi \left(\frac{t_b - t_1}{T}\right) - V_b$$

or,

$$V_b = 2 V_1 \cos 2\pi \left(\frac{t_b - t_1}{T}\right) \ldots\ldots\ldots\ldots (84)$$

Denoting the maximum velocity at the outlet by V_m, v will be equal to V_m when $t = t_b + \frac{T}{2}$. Hence,

$$V_m = 2 V_1 \sin 2\pi \left(\frac{t_b - t_1}{T}\right) \ldots\ldots\ldots\ldots (85)$$

Divide both members of Equation (84) by $\sqrt{\frac{g}{D + H_b}}$ and reduce by Equation (16), giving,

$$H_b = 2 H_1 \cos 2\pi \left(\frac{t_b - t_1}{T}\right) \ldots\ldots\ldots\ldots (86)$$

Attention has already been called to the fact that the values of H_b and t_b depend on H_1 and M. Equation (86) shows the relation between these quantities and H_1.

An expression for H_b in terms of M is now required. By definition, the cross-sectional area through which the canal discharges into the reservoir at any instant, t, may be written, $a = A' + H_b\, l \cos 2\pi \left(\frac{t - t_b}{T}\right)$, A' being the area of the canal outlet at mean sea level, and equal to $D\, l$. The quantity of water discharged through this area in the time, dt, will be given by the equation, $dq = a\, v\, dt$.

Substituting in this equation the proper values of a and v expressed in terms of the variable, t, the equation for the differential discharge becomes,

$$dq = \left[D\,l + H_b\,l \cos 2\,\pi \left(\frac{t - t_b}{T}\right)\right] V_m \sin 2\,\pi \left(\frac{t - t_b}{T}\right) dt$$

$$= D\,l\,V_m \sin 2\,\pi \left(\frac{t - t_b}{T}\right) dt + H_b\,l\,V_m \cos 2\,\pi \left(\frac{t - t_b}{T}\right) \sin 2\,\pi \left(\frac{t - t_b}{T}\right) dt. \quad (87)$$

Whence, by integration,

$$Q = \int_{t_b}^{t_b + \frac{T}{2}} dq = \frac{D\,l\,V_m\,T}{\pi} \quad (88)$$

If Equations (84) and (85) are squared and added, $4\,V_1^2 = V_b^2 + V_m^2$. Whence,

$$V_m = \sqrt{4\,V_1^2 - V_b^2} \quad (89)$$

From Equation (16), $V_1 = \dfrac{\sqrt{g}\,H_1}{\sqrt{D + H_b}}$ and $V_b = \dfrac{\sqrt{g}\,H_b}{\sqrt{D + H_b}}$.

Substituting in Equation (89),

$$V_m = \sqrt{\frac{4\,g\,H_1^2}{D + H_b} - \frac{g\,H_b^2}{D + H_b}} = \sqrt{\frac{4\,g\,H_1^2 - g\,H_b^2}{D + H_b}} \quad (90)$$

giving for Q,

$$Q = \frac{D\,l\,T}{\pi} \sqrt{\frac{4\,g\,H_1^2 - g\,H_b^2}{D + H_b}} = 2\,M\,H_b \quad (91)$$

in which, H_b is the only unknown quantity.

Let it be assumed that $\dfrac{g\,D^2\,l^2\,T^2}{4\,M^2\,\pi^2} = K$, and reduce Equation (91) to the form, $H_b^2\,(D + H_b) = K\,(4\,H_1^2 - H_b^2)$, or,

$$H_b^3 + (D + K)\,H_b^2 = 4\,K\,H_1^2 \quad (92)$$

which is the required solution, K being the factor the value of which depends on M.

Should the semi-amplitude of any one or of all three of these principal component waves be of such magnitude, or should the canal be of such a short length that their subsequent reflections would be of sufficient importance to come within the usual limits of observation, they would require to be accounted for in the computation. For this purpose the corresponding semi-amplitudes of these various reflections will be designated H_3, H_4, etc., as before, for the various reflections of the sea wave, and H_{b3}, H_{b4} etc., for the semi-amplitudes of the reflections of the basin wave. The general equations for heights of tide and velocity of flow at any point in the canal will be, therefore,

$$h = H_1 \cos 2\,\pi \left(\frac{t - t_1}{T}\right) - H_2 \cos 2\,\pi \left(\frac{t - t_2}{T}\right) + H_3 \cos 2\,\pi \left(\frac{t - t_3}{T}\right)$$

$$- H_4 \cos 2\,\pi \left(\frac{t - t_4}{T}\right) + \text{etc.}, + \left[H_{b1} \cos 2\,\pi \left(\frac{t - t_{b1}}{T}\right)\right.$$

$$\left. - H_{b2} \cos 2\,\pi \left(\frac{t - t_{b2}}{T}\right) + H_{b3} \cos 2\,\pi \left(\frac{t - t_{b3}}{T}\right) - \text{etc.}\right] \quad (93)$$

$$v = V_1 \cos 2\pi \left(\frac{t - t_1}{T}\right) + V_2 \cos 2\pi \left(\frac{t - t_2}{T}\right) - V_3 \cos 2\pi \left(\frac{t - t_3}{T}\right) + V_4 \cos 2\pi \left(\frac{t - t_4}{T}\right) + \text{etc.}, - \left[V_{b1} \cos 2\pi \left(\frac{t - t_{b1}}{T}\right) + V_{b2} \cos 2\pi \left(\frac{t - t_{b2}}{T}\right) - V_{b3} \cos 2\pi \left(\frac{t - t_{b3}}{T}\right) + \text{etc.}\right] \ldots\ldots (94)$$

The times of occurrence of the maximum heights and velocities at any point may be found by equations similar to Equations (53) and (54).

Inspection of Equations (84) and (86) shows that the maximum possible value of V_b is $2\ V_1$, and of H_b is $2\ H_1$, occurring when $t_b = t_1$. These substitutions in Equation (83) show the value of v to be zero for all values of t. This is manifestly the limiting case when the reservoir area has become so small as to disappear, and the canal has a "dead end".

The value of v is maximum at a time, $\frac{1}{4}\ T$, later than t_b. Its maximum possible value is $2\ V_1$, which can occur only when t_b and t_1 differ by $\frac{1}{4}\ T$; that is, when the basin is completely filled, or after the wave of translation has poured its entire volume into the basin. This can occur only when the basin is of such large extent that its level cannot be raised by this volume. It is apparent that if the level should be raised, an opposed wave would be generated, which would prevent the entire volume from entering the basin. This limiting condition then becomes the same as the case of an infinitely large reservoir.

It will probably be possible in any practical example of canal and basin of this type to observe both H_b and t_b directly, from which, H_1 can be found at once by means of Equation (86), and, consequently, the frictional coefficient by Equation (26). No example of this case in Nature is known to the writer with the exception of some small coastal bays connected with the sea by channels of various lengths and characteristics. Usually these channels are very short, since the bays are generally close to the ocean. The shorter the length of such channels, the greater will be the number of reflected waves that will be generated by the rise of the bay tide as well as by that of the sea tide. Equations (93) and (94) will then contain many terms in the last members, and their solution will be long and tedious. For such short canals the current may be assimilated, with possibly equal accuracy, to flow under the influence of a surface slope, always assuming the canal to be of short length. This method of solution has been described in a previous article.[18] It is the solution that will generally be found to be more suitable for this case, and of sufficient accuracy for all practical purposes.

CANAL CONNECTING TWO BODIES OF WATER EACH HAVING AN INDEPENDENT TIDE OF ITS OWN

When a canal connects two bodies of water each having an independent tide of its own, no matter what the source of either tide may be, there occurs in the canal an interference of two opposed systems of waves, each system completely independent of the other. In the two cases heretofore discussed, all the various waves simultaneously affecting the surface of the canal could be considered as pertaining to a single system, since each and every wave was dependent in some manner on the primary wave of the sea as a generator. If the generating wave disappeared, all the various reflected waves also disappeared. The present case is that in which two such systems simultaneously affect the surface of the canal and are propagated in opposite directions.

---

[18] "Inlets on Sandy Coasts," by Earl I. Brown, *Proceedings*, Am. Soc. C. E., February, 1928, Papers and Discussions, pp. 505-553.

Since the two systems are independent, it is apparent that the two primary generating waves—that is, the respective primary waves pertaining to the two bodies of water connected by the canal—may have any possible phase relation at a given point in it from complete coincidence to complete opposition, and their amplitudes may have any ratio between their respective magnitudes. If such amplitudes are equal and opposite in phase at certain points, there will be complete disappearance of variation in tidal height at these points. In general, the amplitudes at the two ends of the canal will not be equal, and the phase differences of the two generating waves will be greater than zero.

The method of solving the problem of determining the actual or resultant amplitude of the tides and velocity of flow at any given point in this case must be apparent from what has already been demonstrated in the two preceding cases.

If the subscripts, a and b, are used to characterize each wave system, respectively, the equation for height of the major and minor wave systems each will be,

$$h_a = H_{a1} \cos 2\pi \left(\frac{t - t_{a1}}{T}\right) - H_{a2} \cos 2\pi \left(\frac{t - t_{a2}}{T}\right) + H_{a3} \cos 2\pi \left(\frac{t - t_{a3}}{T}\right) - H_{a4} \cos 2\pi \left(\frac{t - t_{a4}}{T}\right) + \text{etc} \ldots\ldots (95)$$

and,

$$h_b = H_{b1} \cos 2\pi \left(\frac{t - t_{b1} + d}{T}\right) - H_{b2} \cos 2\pi \left(\frac{t - t_{b2} + d}{T}\right) + H_{b3} \cos 2\pi \left(\frac{t - t_{b3} + d}{T}\right) - H_{b4} \cos 2\pi \left(\frac{t - t_{b4} + d}{T}\right) + \text{etc} \ldots (96)$$

in which, d equals the difference in time between the arrival of high water at the respective ends of the canal. It is positive when the minor wave arrives the earlier.

The corresponding equations for velocity will be,

$$V_a = V_{a1} \cos 2\pi \left(\frac{t - t_{a1}}{T}\right) + V_{a2} \cos 2\pi \left(\frac{t - t_{a2}}{T}\right) - V_{a3} \cos 2\pi \left(\frac{t - t_{a3}}{T}\right) + \text{etc} \ldots\ldots (97)$$

$$V_b = V_{b1} \cos 2\pi \left(\frac{t - t_{b1} + d}{T}\right) + V_{b2} \cos 2\pi \left(\frac{t - t_{b2} + d}{T}\right) - V_{b3} \cos 2\pi \left(\frac{t - t_{b3} + d}{T}\right) + \text{etc} \ldots\ldots (98)$$

According to the principles discussed in connection with Equation (32), $h = h_a + h_b$ and $v = v_a - v_b$, or,

$$h = H_{a1} \cos 2\pi \left(\frac{t - t_{a1}}{T}\right) - H_{a2} \cos 2\pi \left(\frac{t - t_{a2}}{T}\right) + H_{a3} \cos 2\pi \left(\frac{t - t_{a3}}{T}\right)$$
$$- H_{a4} \cos 2\pi \left(\frac{t - t_{a4}}{T}\right) + H_{b1} \cos 2\pi \left(\frac{t - t_{b1} + d}{T}\right) - H_{b2} \cos 2\pi \left(\frac{t - t_{b2} + d}{T}\right)$$
$$+ H_{b3} \cos 2\pi \left(\frac{t - t_{b3} + d}{T}\right) - H_{b4} \cos 2\pi \left(\frac{t - t_{b4} + d}{T}\right) + \text{etc.} \quad (99)$$

and,

$$v = V_{a1} \cos 2\pi \left(\frac{t - t_{a1}}{T}\right) + V_{a2} \cos 2\pi \left(\frac{t - t_{a2}}{T}\right) - V_{a3} \cos 2\pi \left(\frac{t - t_{a3}}{T}\right)$$
$$- V_{b1} \cos 2\pi \left(\frac{t - t_{b1} + d}{T}\right) - V_{b2} \cos 2\pi \left(\frac{t - t_{b2} + d}{T}\right)$$
$$+ V_{b3} \cos 2\pi \left(\frac{t - t_{b3} + d}{T}\right) \quad \ldots\ldots (100)$$

To find the coefficient of friction: If Equation (100) is divided by $\sqrt{\dfrac{g}{D + h_a + h_b}}$ and then added to the actual head or height of tide (Equation (99)), thus,

$$h + v\sqrt{\frac{D + h_a + h_b}{g}} = 2 H_{a1} \cos 2\pi \left(\frac{t - t_{a1}}{T}\right) - 2 H_{b2} \cos 2\pi \left(\frac{t - t_{b2} + d}{T}\right)$$
$$+ 2 H_{b3} \cos 2\pi \left(\frac{t - t_{b3} + d}{T}\right) - 2 H_{b4} \cos 2\pi \left(\frac{t - t_{b4} + d}{T}\right) + \text{etc.} \quad (101)$$

It will be noted from Equation (96) that this expression may be written:

$$h + v\sqrt{\frac{D + h_a + h_b}{g}} = h + h_v = 2 H_{a1} \cos 2\pi \left(\frac{t - t_{a1}}{T}\right)$$
$$+ 2\left[h_b - H_{b1} \cos 2\pi \left(\frac{t - t_{b1} + d}{T}\right)\right] \quad \ldots\ldots (102)$$

whence,

$$h_a - h_b + h_v = 2 H_{a1} \cos 2\pi \left(\frac{t - t_{a1}}{T}\right) - 2 H_{b1} \cos 2\pi \left(\frac{t - t_{b1} + d}{T}\right). \quad (103)$$

At the end of the canal from which the major wave comes, $H_{a1} = H_{a0}$; $t_{a1} = 0$; $H_{b1} = H_{bL}$; $t_{b1} = t_{bL}$; $h_b = 0$; hence, $h_a + h_v = 2 H_{a0} \cos 2\pi \dfrac{t}{T} - 2 H_{bL} \cos \pi \left(\dfrac{t - t_{bL} + d}{T}\right)$. Substituting for h_a its equivalent, $H_{a0} \cos 2\pi \dfrac{t}{T}$, the value of h_v is found to be equivalent to,

$$h_v = H_{a0} \cos 2\pi \frac{t}{T} - 2 H_{bL} \cos 2\pi \left(\frac{t - t_{bL} + d}{T}\right) \quad \ldots\ldots (104)$$

For $t = 0$,

$$h_v = H_{a0} - 2 H_{bL} \cos 2\pi \left(\frac{t_{bL} + d}{T}\right) \quad \ldots\ldots (105)$$

At the end of the canal from which the minor wave comes, $H_{a1} = H_{aL}$; $t_{a1} = t_{aL}$; $H_{b1} = H_{b0}$; $t_{b1} = 0$; $h_a = 0$; whence,

$$- h_b + h_v = 2 H_{aL} \cos 2\pi \left(\frac{t - t_{aL}}{T}\right) - 2 H_{b0} \cos 2\pi \left(\frac{t + d}{T}\right) \ldots (106)$$

Substituting, $h_b = H_{b0} \cos 2\pi \left(\frac{t+d}{T}\right)$, and $t = -d$, in Equation (106):

$$h_v = 2\, H_{aL} \cos 2\pi \left(\frac{d + t_{aL}}{T}\right) - H_{b0} \ldots\ldots\ldots\ldots (107)$$

It is apparent from Equations (105) and (107) that the frictional coefficient can be computed from either of these combined with Equation (26), after measurement of the velocity at high water at either or both ends of the canal, and substituting the equivalent velocity head in the proper one of these equations, in which all terms will be known but H_{bL} or H_{aL}, and t_{bL} or t_{aL}. The latter may be computed with sufficiently close approximation from the known depths and heights of tide, thus fixing H_{bL} or H_{aL} for substitution in Equation (26). The measurement at the end from which the minor wave comes will usually be found the more satisfactory, thus giving H_{aL} which is larger than H_{bL}.

Application to Existing Canals.—There are a great many examples of canals of this type, such as the English Channel, the St. Georges Channel, Seymours Narrows, Deception Pass, the Cape Cod Canal, and the Chesapeake and Delaware Canal.

The English Channel is an example of the longer canals of this type. Its tides are the resultant of the interference of two unequal opposed waves. The major or Atlantic wave enters from the south end, with an amplitude of 16 to 18 ft. The minor wave enters from the North Sea with an amplitude of about 10 ft.

The length of the Channel is great compared with that of the wave, hence there is sufficient room in it for the development of all the phenomena of wave interference anticipated from theoretical considerations. A complete description of these phenomena is given by Bourdelles[13] and will not be repeated here.

The case of the interference of two equal opposed waves is realized in the St. Georges Channel of the Irish Sea. Two flood currents having opposite directions, exist simultaneously and proceed from the ends of the channel toward the line of flood which forms a line joining the Isle of Man with Morecambe Bay, so that the sea rises on that line to a maximum height, but is accompanied by no current. Likewise, on the ebb, two opposed ebb currents start from this line directed toward the ends of the channel. At the place where the trough of one of the waves encounters the summit of the other, the vertical variation of the tide is zero, while the currents there reach their greatest velocity. This occurs at Coustown and at a point 50 miles south of Dublin. These ebb and flood currents turn throughout the channel at the time of high and low water at the line of flood; likewise, the time of maximum velocity throughout the channel corresponds to that of half tide at this line.

The Cape Cod Canal is an example of the shorter canals subject to unequal opposed waves.[19] The canal is about 8 miles long. The amplitude of the tide in Cape Cod Bay is about 9 ft. and of that in Buzzards Bay, 4 ft. This canal is so short with respect to the magnitude of its major wave that the number of reflections of the wave through the canal must be large, and the equations corresponding to Equations (99) and (100) would be long and tedious to solve. The writer has not attempted to compute by this theory the tidal characteristics of this canal because data obtained by observation known to him are not sufficiently complete for purposes of comparison.

---

[19] "The Cape Cod Canal," by William Barclay Parsons, M. Am. Soc. C. E., *Transactions*, Am. Soc. C. E., Vol. LXXXII (1918), p. 1.

The Chesapeake and Delaware Canal occupies an intermediate status as to length and depth between the Suez Canal and the Rehoboth Canal. It is the one by which the theory will be further tested. This canal connects the Delaware River with Chesapeake Bay.[20] It begins about 40 miles below Philadelphia, Pa., near Delaware City, Del., and extends for about 14 miles in a westerly direction to Chesapeake City, Md., on Back Creek, an arm of Chesapeake Bay. The canal was designed to afford a sea-level channel between these bodies of water, 12 ft. deep at mean low water, with a bottom width of 90 ft. The sea-level connection was made in February, 1927, and some observations were made on May 13, 1927, to ascertain the tidal conditions.

From previous records there was found to be an average higher high water of 6 ft. above mean low water at the Delaware entrance of the canal, and of 2.4 ft. at Chesapeake City. High water occurs two hours earlier at Chesapeake City than at the Delaware entrance.

The side slopes of the excavated prism are constructed at 2 ft. horizontal to 1 ft. vertical, and the bottom of the canal is uniformly 15 ft. below mean sea level, hence the following data result (see Fig. 16):

$$p = 33.5 + 33.5 + 90 = 157 \text{ ft.}$$

$$l = 30 + 30 + 90 = 150 \text{ ft.}$$

$$A = \frac{1}{2}(150 + 90) \times 15 = 1\,800 \text{ sq. ft.}$$

$$D = \frac{1\,800}{150} = 12 \text{ ft.}$$

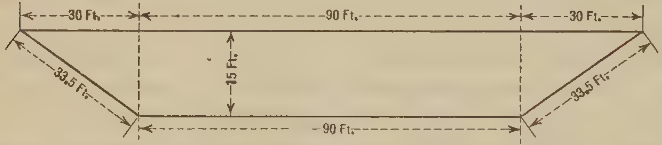

FIG. 16.—DIAGRAMMATIC CROSS-SECTION OF DELAWARE-CHESAPEAKE CANAL.

No opportunity was had to determine the exact value of the coefficient of friction for this canal. It has been shown, however, that a value of 0.51 was proper for channels of the cross-section and depth of the Suez Canal and of 0.58 for the Rehoboth Canal. The value of 0.55 appears to give results in accordance with observations for the Chesapeake and Delaware Canal, and that is the value adopted.

The first three miles of the canal at the Delaware end were constructed wider than the remainder, primarily to obtain more width for vessels to lie at the banks while awaiting passage, and, secondarily, to obtain material to build a dike in the vicinity. This change in width results in the heaping up of the tide at Mile 3, which must be noted in considering the effect of width. It is

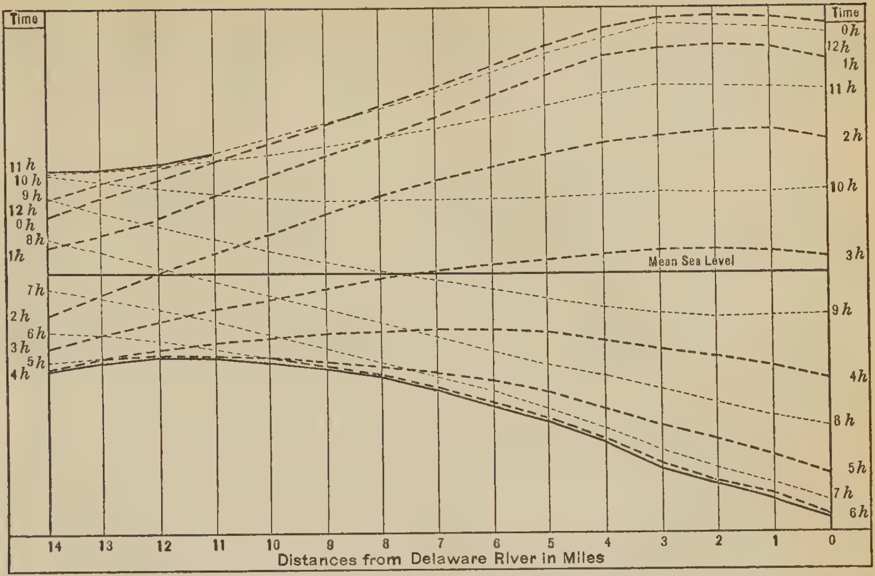

FIG. 17.—COMPUTED INSTANTANEOUS PROFILES IN THE CHESAPEAKE AND DELAWARE CANAL.

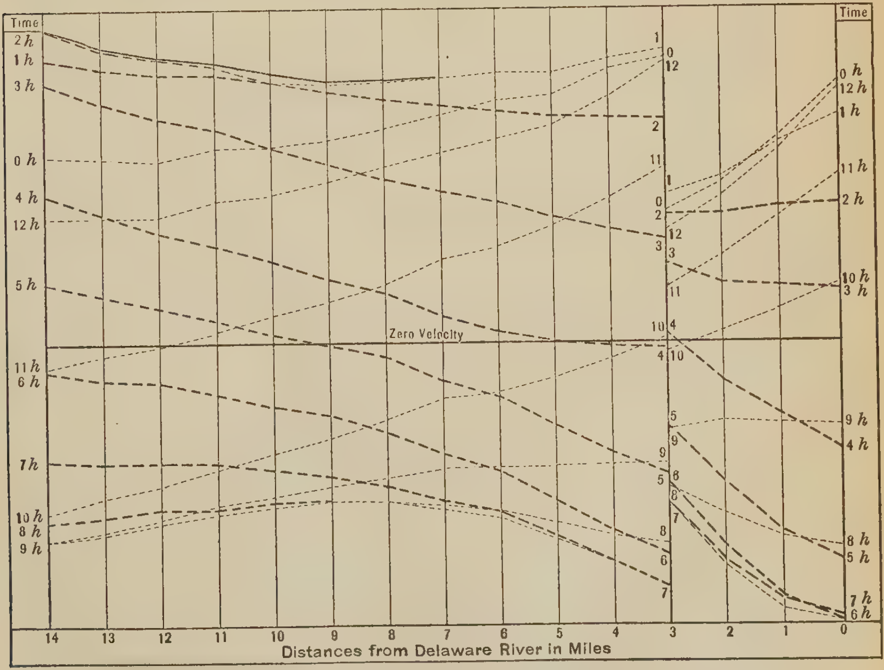

FIG. 18.—INSTANTANEOUS VELOCITIES AS COMPUTED FOR THE CHESAPEAKE AND DELAWARE CANAL.

300 ft. wide at the surface for these 3 miles. Using this width in Equation (26), it is found that the tidal wave of 3 ft. from the Delaware River would be reduced by friction to a semi-amplitude of 2.39 ft. at Mile 3. Substituting the proper values in Equation (37) the new height at Mile 3 is found to be

$$h = \frac{2 \times 2.39 \times 300}{300 + 150} = 3.18.$$

This means that the change of width at Mile 3 causes an increase in semi-amplitude of this wave from 2.39 to 3.18 ft. and creates a positive reflected wave going back to the canal entrance, having a semi-amplitude of 0.79 ft. The effect of this change of width on subsequent reflections is small and is neglected.

Equations resulting from the substitution of the foregoing data in Equations (26) and (99) may be written similar to Equations (65), (66), (67), and (68).

The instantaneous profiles for each hour of the tidal cycle, and the instantaneous velocities for the same times are shown in Figs. 17 and 18.

Fig. 19 shows the record of instantaneous tidal observations made on May 13, 1927. It will be noted that the computed and observed instantaneous curves show a remarkable similarity. If the observations could have been extended to cover, say, a complete lunar period, so as to obtain an average result, a more complete comparison could have been made; yet the results are quite in agreement with the theory.

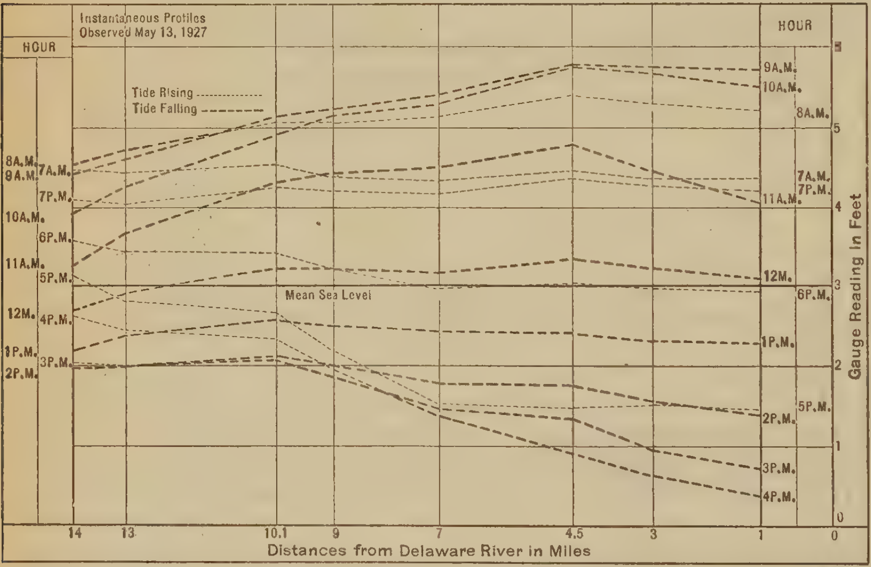

FIG. 19.—OBSERVED INSTANTANEOUS PROFILES IN THE CHESAPEAKE AND DELAWARE CANAL.

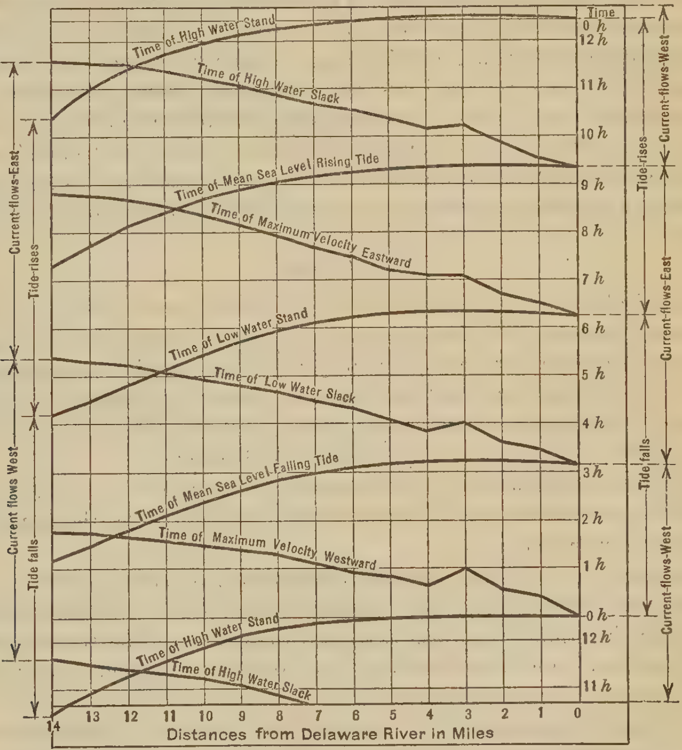
It is regretted that the observations did not include current measurements, but the current meter broke down before the work was well begun. In a general way, however, velocities were found to conform to the indications of theory. For instance, in the first three miles of the canal, the velocities are so low that silt brought in and deposited from the Delaware River which here has a very muddy bottom, has caused such rapid shoaling of the channel in this portion as to require much maintenance dredging. The sudden increase in velocity at Mile 3 is quite marked, and the greater velocity at Mile 14 was such as to cause shipping much concern.

Fig. 20 shows the computed retardations of high and low water, and the times of slack water and maximum velocities. These features were noted in the observations of May 13, 1927, and are also shown in Fig. 20. Here, again, the general appearance and trend of the curves is such as to show that the results given by theory agree quite well with observations. In conformity with the requirements of theory, the rate of propagation of high water is quite slow beginning at Mile 14, from which the rate gradually increases to Mile 6. From the latter point to the canal entrance in Delaware River high water occurs practically simultaneously in the entire section. The point of minimum tidal variation is near Mile 13.



NOTE:- The irregularities in curves at mile 3 are due to a change in width of Canal at that point

FIG. 20.—RETARDATIONS OF HIGH AND LOW WATER, AND OF MAXIMUM VELOCITIES, THE CHESAPEAKE AND DELAWARE CANAL.

Beginning at high water at the Delaware entrance, the rate of propagation of the maximum velocity westward is fairly uniform in a westerly direction.

The only change of importance in this rate is at Mile 3, where irregularities are due to the change of width of the canal at that point. It will be noted that the time of maximum velocity westward occurs at Mile 14, somewhat after the level has fallen below mean sea level. Between Miles 11 and 12, slack water occurs on high and low-water stands, so that, in general, the period of falling tide corresponds to that of a westerly current and the period of rising tide to that of an easterly current. At the Delaware entrance, on the contrary, the current is westerly as long as the tide is above, and easterly as long as it is below, mean sea level. Mean canal level will be found above mean sea level at all points between its two ends.

Theory and observation both reveal a lack of similarity between the geometric loci of high and low water, due to the greater effect of friction on the negative waves. The effect of change of width at Mile 3 is more marked on the positive waves than on the negative. This change of width is shown to be very detrimental to the canal. Had these three miles been uniform in width with the remainder of the canal, the increase in height of the tidal wave there would not have occurred, and the wave throughout the remainder of the canal would have been lessened, thus reducing velocities from Mile 3 to Mile 14, and increasing velocities from Mile 0 to Mile 3. This would have been beneficial to the maintenance of the first 3 miles of canal, and would have been beneficial to navigation in reducing velocities in the remaining 11 miles.

CONCLUSIONS

The tidal phenomena occurring at any point in a canal are manifestations of the energy imparted to the water by a source of energy outside the canal. This energy is propagated from point to point in the canal by a simple wave of translation, and manifests itself as potential energy in effecting a change of elevation of the surface of the water, and as kinetic energy in imparting a certain velocity of translation to the particles of water.

All the energy imparted to the water of a canal will ultimately become expended in overcoming the frictional resistance offered by the banks to the movement of the water.

If the canal is too short for this expenditure to become effected during the passage of a single simple wave of translation, the energy remaining unexpended when the simple wave has traversed the canal will be transmitted back through the canal and manifested in the form of a second simple wave of translation, termed a reflected wave.

If the canal terminates in a restricted or dead end, the reflected wave will be of the same sign as to amplitude as the direct wave, but of opposite sign as to velocity.

If the canal terminates in a widening or a basin of large capacity the reflected wave will be of opposite sign as to amplitude and of the same sign as to velocity, as the direct wave.

Whenever two or more simple waves of translation are simultaneously propagated in a canal, whether in the same or in opposite directions, a compound wave is formed, which is the resultant of all the simultaneous simple waves. The resultant amplitude at any point is the algebraic sum of all the component amplitudes at that point, and the resultant velocity, the algebraic sum of all the component velocities, provided all velocities in the direction of propagation of the major wave are considered as positive, and all in the opposite direction, negative. In general, the algebraic sum of the component amplitudes will not bear the same simple relation to the algebraic sum of the component velocities as expressed in Equation (17) for the relation of amplitude to velocity in the simple wave of translation.

The simple wave of translation seldom exists in a state of Nature, and, consequently, can be but rarely observed. Practically all tidal propagation as observed in Nature is in the form of a resultant wave, in which the varying effect of the different components as modified by friction accounts for the varying relation so frequently observed between amplitude of tide and velocity of current at any given point.

Shallow channels are conducive to high velocities of tidal currents, with rapid absorption of energy, which reduces velocity. Deep channels are conducive to moderate current velocities, but absorb energy slowly, which tends to maintain currents at the same velocity.

As long as the width of a tidal channel is uniform, the magnitude of the width has little or no effect on velocity or other phases of tidal propagation. Any variation in the width of a tidal channel will affect the rate of expenditure of energy, and, consequently, it will affect both amplitudes and velocities in any canal.

DISCUSSION

R. L. FARIS,[21] M. AM. SOC. C. E. (by letter).—This paper is an important contribution to a subject that is beset with many complexities. Throughout the world, and more especially in the United States, the subject of tides has been developed very largely by the mathematician whose interest, primarily, was in other than the engineering phases of the subject. It is gratifying, therefore, to find the fundamental problems of the subject successfully attacked from the engineering point of view.

In introducing Table 3, under the heading, "Heights", the author states that,

> "It is the practice of the United States Coast and Geodetic Survey to allow for lack of symmetry between positive and negative waves in making tidal predictions by introducing a 'shallow-water' component into the computations."

This may leave an erroneous impression with the reader not familiar with the problem of the prediction of tides, and it appears desirable to amplify the subject somewhat.

In connection with the prediction of tides it is unnecessary to assume the existence either of positive or negative waves in the sense used by the author. The problem centers in the resolution of the tides, as actually observed at any given place, into a number of simple cosine curves each having a definite period, amplitudes, and phase. As soon as these become known, the tide for any future time can be predicted by combining these simple cosine curves for the time in question. Technically, each of these simple curves is spoken of as a component of the tide.

The periods of the primary components of the tide are derived from astronomic considerations, and, on the open coast, the tide as actually observed can be closely represented by the combination of a number of such components. However, in traversing the shallow waters of tidal rivers, or other like bodies of water, the open ocean tide becomes distorted or modified.

The modification that the tide undergoes in its progress up a tidal river is illustrated in Fig. 21 which represents the rise and fall of the tide at Fort Hamilton, New York, and Albany, N. Y., for the 2-day period, May 20 and 21, 1914. The lower curve is the tide curve for Fort Hamilton, which may be regarded as situated near the mouth of the Hudson River, while the upper curve is the tide curve for Albany, near the head of tide-water on the Hudson, about 130 nautical miles above Fort Hamilton.

The tide curve for Fort Hamilton is representative of the tide on the open coast in that the durations of rise and fall are approximately equal. This is evidenced by the symmetry of the curve. At Albany, however, the tide has become modified considerably. In overcoming the friction against its progress up stream, the duration of rise has become shortened, giving a corresponding increase to the duration of fall. In Fig. 21 this is represented by the steepness of the rise of the tide which contrasts markedly with the much gentler slope of the fall.

---

[21] Asst. Director, U. S. Coast and Geodetic Survey, Washington, D. C.

In resolving river tides into their constituent simple tides for the purposes of prediction, the so-called shallow-water components come to light, quite apart from the causes which bring them about. In this connection, therefore, it is better not to speak of "introducing" shallow-water components, because these exist in, and must be taken into account in the prediction of, river tides.

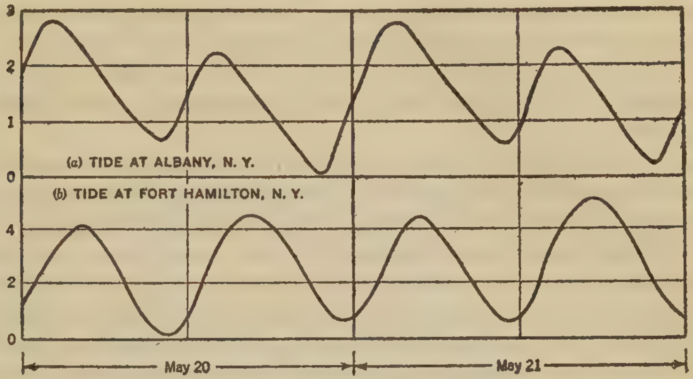


FIG. 21.—TIDE CURVES AT ALBANY, N. Y., AND FORT HAMILTON, NEW YORK, FOR MAY 20 AND 21, 1914.

G. T. RUDE,[22] M. AM. SOC. C. E. (by letter).—In the closing discussion of the paper, "Tides and Their Engineering Aspects",[23] the writer made the statement that Colonel Brown had had charge of the lowering of the Chesapeake and Delaware Canal to sea level, and that any studies he had made of wave propagation in the canal would be awaited with interest. The Engineering Profession is indeed indebted to Colonel Brown for this contribution to the subject of restricted and complex tidal flow.

The writer desires to preface this discussion with the explanation that, while exception is taken to certain statements regarding ocean currents and the dominant tides of the oceans, which are considered not in entire accord with these phenomena as accepted by tidal students, it is obvious that they are used by Colonel Brown merely to round out his paper. In no way do they detract from the value of the study as to the flow of water in tidal canals, assuming for the moment that the writer's statements as to these phenomena are the correct ones.

Undoubtedly, from his exhaustive study, Colonel Brown can easily and successfully clarify one phase of his "reflected wave" theory. A visualization of a reflected wave, in the case of a canal with a dead end, is not difficult, nor is its agency in consuming the unexpended energy of the wave upon arrival at the end. In the case of the canal with an outlet into a body of water, however, it would appear that the propagation of the wave would continue out into the outlet body in its original form and be dissipated in that body instead of being propagated back into the canal as a "reflected wave".

---

[22] Commander, U. S. Coast and Geodetic Survey, Washington, D. C.

[23] *Transactions*, Am. Soc. C. E., Vol. 92 (1928), p. 711.

In the definitions, Colonel Brown uses the term, "strength of the tide", apparently with reference to the current. It is suggested, for uniformity in the nomenclature of this particular subject, that the term, "current", be applied to the horizontal movement of the water, and the term, "tide", to the periodic vertical movement. The term, "tide", also appears to be limited to the motion of a "derived" wave.

"Mean canal level" or "mean river level" is taken as the mean of the high and low-water levels at any point. It is customary, however, among tidal mathematicians to differentiate between "mean sea level", "mean river level", or "mean canal" and "mean tide level". The term, "mean tide level", is applied to the plane exactly half-way between the high and low waters and is obtained by taking one-half the sum of all high waters and low waters. Mean sea level, however, is obtained by integrating the tide curve, at least to the extent of taking the average height of the curve at frequent intervals. It is customary to use the hourly heights for this purpose. Mean river level or mean canal level is the mean height of the water surface as influenced by the tide, freshets, and bottom slope, and is obtained in the same manner as mean sea level.

The difference between mean tide level and mean sea level, however, is small, and if the series of observations is short, the two planes may be considered for practical purposes as coincident. On the Atlantic Coast the plane of mean sea level lies above the plane of mean tide level—at Portland, Me., 0.03 ft.; at New York, N. Y., 0.05 ft.; at Atlantic City, N. J., 0.03 ft.; and at Fernandina, Fla., 0.10 ft. On the Pacific Coast mean sea level is the lower of the two—at Seattle, Wash., 0.01 ft.; at San Francisco, Calif., 0.06 ft.; and at San Diego, Calif., 0.05 ft. This difference in elevation of the two planes is due to the fact that the tide curve is not a simple sine curve; actually, the larger part of the curve may be above or below the mean level of the water as determined from the average of the high and low waters.

Apparently, the hydraulic characteristics in the canal are not taken into consideration. The tidal data for the Chesapeake and Delaware Canal, furnished the U. S. Coast and Geodetic Survey by the Army Engineer Corps, appear to indicate that the current is primarily hydraulic in the western portion of the canal, although it loses this characteristic at the Delaware Bay end. The present current predictions made by the Coast and Geodetic Survey in the Atlantic Coast Current Tables are for the location of the railroad bridge. These predictions are based on the assumption that the current is hydraulic at that point.

Under the paragraph, "Tidal Waves in the Sea", Colonel Brown states that tidal currents in shallow waters near the shore line are mass currents acting for the entire depth of the sea. Observations indicate that, in rivers and canals, the maximum velocity is just below the surface. Mr. Parsons calls attention to this fact in his paper on the Cape Cod Canal.[19] Current observations made by the U. S. Coast and Geodetic Survey have shown varying results in short series. The observations, however, over a longer series substantiate Mr. Parsons' statement. At the principal station of a section of the Boston Harbor Current Survey by the Coast and Geodetic Survey, near Deer Island Light, where fourteen days of observations were obtained, the following velocities were observed at flood strength: 7-ft. depth, 3.78 knots; 13-ft. depth, 3.81 knots; 32-ft. depth, 3.77 knots; and 51-ft. depth, 3.75 knots. The corresponding directions were 267°, 270°, 271°, and 268°, showing little variation in direction.

In the open ocean, however, where the terrain has little or no influence, the currents act with ever-decreasing velocity with the increase in depth and, too, the direction changes constantly as the depth increases, clockwise in the Northern Hemisphere and counter-clockwise in the Southern Hemisphere.

In the paragraph mentioned, Colonel Brown also states that:

> "The currents [in the open sea] sometimes become gyratory because of the combination of longitudinal currents with lateral currents which come and go, corresponding to the alternate rise and fall of the water on shore, or of the crossing of two co-existent waves, the directions of which intersect at an angle."

The work of an internationally known mathematician, corroborated by actual observations of ocean currents, demonstrates that this gyratory or rotary movement is a distinct and ever-present characteristic of these currents, not only along the coasts, but over the entire ocean. These phenomena were first suspected by Fridtjof Nansen in his historic drift in the Arctic ice pack during 1893-1896.

Nansen's deductions were reported to Helland-Hansen, who demonstrated mathematically that this rotary movement is due to the deflective force of the earth's rotation, the direction of rotation of the currents being clockwise in the Northern Hemisphere and counter-clockwise in the Southern Hemisphere. Nansen's theory of this rotary movement has been proved as an ever-present characteristic of ocean currents, not only by the mathematics of Helland-Hansen, but also by actual current observations made since 1915 by the U. S. Coast and Geodetic Survey on every light-vessel along both coasts of the United States. It has also been checked in the open ocean by Helland-Hansen, utilizing innumerable reports of current effect upon ocean-going vessels.

These ocean currents are never slack,[24] their direction changing continually in a rotary movement at an average rate of about 30° per hour for semi-diurnal currents. At the station of observation the velocities vary throughout a tidal cycle and the directions and velocities at a station, plotted to scale, roughly approximate an ellipse.

It appears that Colonel Brown has not accepted the "stationary wave theory" of Harris as an explanation of the changed regimen of the tide in certain bodies of water in which the tide occurs almost simultaneously throughout the entire length of the body and in which the turn of the current occurs near the time of high and low water instead of at the time of half-tide. Under the heading, "Tidal Waves in the Sea", Colonel Brown states:

---

[24] "Tides and Their Engineering Aspects," *Transactions*, Am. Soc. C. E., Vol. 92 (1928), p. 656.

> "In general, near the coast line, the situation is intermediate between the state of free propagation of the tidal wave, and that of filling a basin of small dimensions; the regimen of the tide becomes changed. The reversal or turn of the tide [current] is then no longer effected at mid-tide, but approaches closer to the times of high and low water, and the maximum velocity approaches mid-tide. The velocities then differ from their theoretical value and, in order to interpret the phenomena observed, one is tempted at times to have recourse to considerations based upon the hydraulics of running water and the influence of surface slope. Under these conditions the tidal wave loses its usual characteristics, entirely or in part, and in order to account for observed facts, it must be considered as formed by a series of small waves of translation each of which is propagated according to its own proper law."

Harris' stationary wave theory accounts for these and other apparent anomalies in the tides in a more rational manner than the older theories and it is being accepted both in the United States and abroad. This theory would explain the dominant tides of the world as the results of oscillations or stationary waves, set up and maintained by the periodic tidal forces of moon and sun. In most inland bodies of water connected with the ocean the tide is due to a progressive wave thrown out by a near-by stationary wave in the ocean. In a body of water, however, of a size and depth to maintain an independent stationary wave, the tides may be caused by its own stationary wave.

It could be shown that Harris' stationary wave theory[25] furnishes a logical explanation of the tidal characteristics of some regions, which differ from the usual tidal regimen, such as the reversal of the current at the time of high and low water instead of at the time of mid-tide, mentioned in Colonel Brown's paper; the almost simultaneous occurrence of high or low water throughout the length of the body; the increase of the range toward the head of the body, represented in the large range at the head of the Bay of Fundy; and the strictly solar tide of the Island of Tahiti, with its high and low waters occurring at about noon and midnight, and about six o'clock in the morning and evening.

Under the heading, "Canal Connecting Two Bodies of Water Each Having an Independent Tide of Its Own", Colonel Brown accepts the theory advanced in the past by some engineers, that the characteristics of the tidal movement in such canals, for example, Seymour Narrows, Deception Pass, East River, etc., are due to the interference of two opposed systems of waves, each independent of the other. The evidence, however, from direct tidal and current observations, supported by the accuracy of predictions of tides and currents based on hydraulic considerations, indicates that the movement of the water in such straits is primarily hydraulic, brought about by the difference of the tidal characteristics in the connected bodies of water and the differences in the time and height of the tide in the two bodies.[26]

[25] Manual of Tides, Pt. IV *A*, Appendix 7, Rept. of U. S. Coast and Geodetic Survey, 1900, and Pt. IV *B*, Appendix 5, Rept. of U. S. Coast and Geodetic Survey, 1904.

The writer would like to inquire of Colonel Brown whether the values in the columns headed "Bourdelles" and "Lévy" in Tables 3, 4, and 5, are observations made by Bourdelles and Lévy with which the computed values in the column, "Present Theory" are compared, or whether they are values computed by Bourdelles and Lévy compared with computed values by the "Present Theory"?

EUGENE E. HALMOS,[27] M. AM. SOC. C. E. (by letter).—The writer has given careful attention to this paper, not only because of its general appeal to engineers interested in the science of hydraulics, but particularly because of the references made therein to the paper describing the Cape Cod Canal,[19] in the development of the mathematical portion of which the writer had the privilege of collaborating with Mr. Parsons.

The analysis of the tidal flow in canals presented in Mr. Parsons' paper followed the theory of Professor Maurice Lévy, which, in turn, is based on d'Alembert's theorem defining the interdependence of the free surface of a fluid in motion and the forces acting on its mass. The derivation of the formulas is strictly rational, their application being restricted only by the requirement of comparatively small tidal variations in relation to the depth of the canal.

In his study Colonel Brown starts with an equation (Equation (15)) which the writer considers empirical and in which the velocity of the current is assumed to be a very simple function of the speed of propagation, the depth of the canal, and the height of the tide at the summit of the wave. He then uses this value of the velocity in expressing the energy contained in the wave and the work done by friction in destroying this energy. From this empirical beginning, the author, by the application of well-established principles of hydrodynamics, and especially by the introduction of his very ingenious theory of the reflected wave from the reservoir, arrives at formulas and methods of treatment of the problem which are applicable to the varying conditions that may be encountered in tidal canals.

The author's treatment of the subject does not limit the use of his method and formulas to comparatively small tidal variations. It permits the consideration of friction in such a manner as to prove that its effect in modifying the height and the speed of the wave is greater for the negative than for the positive wave. This the writer believes to be an important advance in the study of tidal canals. The demonstration of the effect of interference of opposed waves is clear, instructive, and useful.

The author has shown that by his theory a very close check on both tidal heights and current velocity is obtained when applied to the Suez Canal. However, as stated by Mr. Parsons,[28] a similar agreement of computed and observed results is found with the Lévy formulas if the frictional coefficient is so modified that friction, as a linear function of the mean velocity, will absorb the same total energy as if its variation depended on the square of the velocity. On the other hand, the two methods seem to give appreciably different results in the case of more shallow canals with comparatively large tidal variations. An inspection of Fig. 10 in the author's paper on "The Chesapeake and Delaware Canal"[29] and Fig. 17 and Fig. 19 of his present paper, at once reveals the fact that the tidal elevations computed by his method more closely approximate the observed profiles.

[26] "Tides and Their Engineering Aspects", *Transactions*, Am. Soc. C. E., Vol. 92 (1928), pp. 713-715.

[27] Chf. Engr., Parklap Constr. Corp., New York, N. Y.

[28] *Transactions*, Am. Soc. C. E., Vol. LXXXII (1918), p. 121.

It appears that, while the mathematical basis of the analysis given in Mr. Parsons' paper is more rational, the results obtained from the formulas deduced by the author may conform better to actual observation for a wider range of conditions.

In the writer's opinion, the empiricism of Equation (15) does not seriously impair the validity of the author's formulas. He believes, however, that the method shown by Colonel Brown for the evaluation of the frictional coefficient, F, is of doubtful practical value. This method calls for the actual measurement of the velocity, V_0, at the outlet of the canal, which, of course, cannot be done before the canal is completed. For the design, therefore, this basic quantity is not available and must be evaluated by comparison with existing canals. As it is not likely that such canals, with closely similar cross-section, length, tidal conditions, and consistency of canal bed, could be easily found, the writer feels that it would be better to follow Mr. Parsons' suggestion and determine V_0 by one of the approximate methods given in his paper on the Cape Cod Canal.

Under "General Remarks", the author states that no theory can adequately and completely solve the complex problems which the regimen of the tide raises in practice and that such complete solution "must forever escape satisfactory analysis". In this, there is a complete agreement between the author and Mr. Parsons, who concluded that numerous necessary assumptions, which are never quite true in practical cases, "*a priori* reduce all analytical results to a grade of a more or less fair approximation". However, Mr. Parsons went further than the author when he definitely stated that, in his opinion, approximate methods of calculation should be used for the practical evaluation of the velocities in canals subjected to tidal influences.[30] On the basis of the theoretical studies, Mr. Parsons suggested the use of particular approximate formulas for different types of canals characterized by the product of their length and the factor, q, the value of which was given in his Equation (8).[31]

The writer found that this product for the Chesapeake and Delaware Canal amounts to 0.972 for the 11 miles between Mile 3 and Mile 14. It, therefore, would come under the Classification (c), as defined[32] in the paper on the Cape Cod Canal. For this type, Mr. Parsons recommended the use of the formulas of the French Academy of Sciences[33] as likely to give close results for practical purposes, both as to tidal elevations and maximum current velocities. The writer was unable to make a numerical check, by the use of these formulas, against the values computed by the author, because the published diagrams (Figs. 17 and 18) do not show the scale of either heights or velocities, nor could he check against observed current velocities as actual data are not yet available. The writer would suggest that the author make such a check when current velocity measurements will furnish sufficient information on the Chesapeake and Delaware Canal and in this manner establish whether or not the recommendations made by Mr. Parsons as to the limits for the use of the proper approximate formulas need to be revised.

[33] *Loc. cit.*, p. 138.

Nothing said by the writer in discussing this paper should detract from its value as a treatise of the highest order on the motion of water in tidal canals. The theory of the propagation of waves of translation in canals, conceived by Bourdelles and given mathematical expression by the author expands and completes the work of previous writers on the subject. In this paper, Colonel Brown has made a real and useful contribution to the science of hydrodynamics.

W. M. Black,[34] M. Am. Soc. C. E. (by letter).—The writer deems this paper of great value to the Engineering Profession. It is a distinct contribution to the very limited information heretofore available for determining in advance the movement of water in projected canals designed to connect bodies of water in which the tidal regimens differ. It will also assist in the determination of the effects of changes projected in the cross-sections of canals in which there is tidal action. From personal experience the writer knows how prone many engineers have been to treat tidal currents simply as water flowing under the laws which govern the uniform flow of water in pipes and channels under a fixed head. Too little weight has been given to the wave action propagated in advance of the current when the head in a stream is increased by an influx. McAlpine demonstrated this fact in the latter part of the Fifties and in the Nineties the late Brig.-Gen. Amos Stickney, U. S. A., reported the same phenomenon in his discussion of flood movements in the Mississippi River where, in the deep channel below the mouth of the Red River, the velocity of advance of the flood wave is five times greater than the maximum current velocity.

The velocity of wave propagation is greater than the velocity of the current and an increase of channel capacity increases the velocity of wave propagation and decreases the velocity of the induced current (Equations (2) and (16)). Therefore, the necessity of considering the changes of head due to the wave movement is apparent when the probable effect of changes in channel depths in waterways subject to tidal action is under study. The problem of the control of current velocities in the East River, New York, is an example.

Colonel Brown's theory seems to be supported in its application to the conditions in the several canals for which sufficient data are available. The writer believes that observations on other tidal canals will give further confirmation. He hopes that investigations along this line will be continued. He also hopes that similar analytical studies will be made of the tidal action in estuaries, such as the Hudson and Delaware Rivers, in which there is a gradual change in the form of the tidal wave from one of oscillation near the entrance from the sea to one of translation farther up the river.

---

[34] Maj.-Gen., U. S. A. (*Retired*), Washington, D. C.

It is only by a more accurate knowledge of the laws which govern the tidal wave action that the problems of the improvement of such estuaries can be solved with any degree of accuracy. Under the pressure of what seemed to be a local necessity, channel widths have been changed recently in the Lower Hudson. The effects of this change on the tidal regimen of the upper river cannot be foretold with any certainty at this time. The entire question of tidal action in inland waters is of the greatest practical importance.

H. F. FLYNN,[35] M. AM. SOC. C. E. (by letter).—In that portion of the paper dealing with the Chesapeake and Delaware Canal, a comparison is made between observation and prediction, but only one day's heights and times and no currents were then available. The purpose of this discussion is to make such a comparison based on reasonably long series of observations. The material that will be used and the derived tidal constants are shown in Table 9.

The elevations in Table 9 refer to the United States Engineer Department datum in the Delaware River. The locations of the tidal stations are as follows: (1) Delaware City, on the west bank of the Delaware River, 1.8 miles above Reedy Point; (2) Reedy Island, on Reedy Island on the west bank of the main channel of the Delaware River, 3.3 miles below Reedy Point; (3) Reedy Point, just inside the outer end of the north jetty at the Delaware River end of the canal; (4) Biddle Point, on the north bank of the canal, 3.1 miles from Reedy Point; (5) Summit, on the bank of the canal at Summit Bridge, 9.2 miles from Reedy Point; (6) and (7) Chesapeake City, on the bank of Back Creek, at the entrance to the canal, 14.0 miles from Reedy Point; (8) Court House Point, on the southeast bank of Elk River, about 1 mile below the mouth of Back Creek and 5 miles from Chesapeake City; (9) Town Point, on the southeast bank of Elk River, about 1.5 miles below Court House Point; (10) Reybolds Wharf, on the southeast bank of Elk River, about 4.5 miles below Town Point; and (11) Frenchtown, on the southeast bank of Elk River, about 5 miles above Court House Point and about 4 miles above the mouth of Back Creek.

Before proceeding with comparisons between the observed and predicted tides in the canal proper, it will be well to look into conditions at the entrances before and after the canal was opened to tidal flow. No preliminary observations were made right at Reedy Point, the nearest being those at Delaware City, in 1923, and those at Reedy Island. Interpolating between these values, the resulting lunitidal intervals at Reedy Point are 11.10 hours for high water and 5.76 hours for low water. Comparing these values with those in Table 9, it appears possible that the duration of rising tide may have become somewhat greater than before, which is to be expected. The elevations of high and low water observed at Reedy Point are normal for this part of the Delaware River, but those at Delaware City in 1923 appear to be somewhat low.

---

[35] Engr., U. S. Engr. Office, Philadelphia, Pa.

TABLE 9.—TIDAL DATA IN CHESAPEAKE AND DELAWARE CANAL, AND VICINITY

No.	Station	Year	Series	Lunitidal Intervals, in Hours		Elevations, in Feet		Mean tide level, in feet	Range, in feet
				High water	Low water	High water	Low water		
1	Delaware City	1923	4 months	11.27	5.93	5.97	0.47	3.22	5.50
2	Reedy Island	1929	12 "	10.78	5.45	6.20	0.63	3.42	5.57
3	Reedy Point	1928–29	9 "	11.19	5.59	6.16	0.79	3.48	5.37
4	Biddle Point	1928–29	8 "	11.46	5.90	6.10	1.01	3.56	5.09
5	Summit,	1928–29	9 "	11.18	4.56	5.30	1.93	3.62	3.37
6	Chesapeake City	1923	5 "	9.28	3.32	4.47	2.15	3.31	2.32
7	Chesapeake City	1928–29	9 "	9.81	3.64	4.53	2.23	3.38	2.30
8	Court House Point	1929	7 "	9.04	3.09	4.32	2.10	3.21	2.22
9	Town Point	1898–1927	26 days	8.97	3.01	....	....	....	2.42
10	Reybolds Wharf	1898–1927	58 "	8.79	2.55	....	....	....	1.93
11	Frenchtown	1899	14 "	8.87	2.93	....	....	....	2.43

At Chesapeake City conditions are very different. High water occurs 0.53 hours, and low water 0.32 hours, later than formerly. There are three stations in Elk River for which tidal constants are published by the U. S. Coast and Geodetic Survey; namely, Town Point, Reybolds Wharf, and Frenchtown. At each of these places one or more short series of observations were made between 1898 and 1927. The means of all results for each station are given in Table 9. Comparing the lunitidal intervals from seven months' observations at Court House Point in 1929 with the intervals at the neighboring stations, it is apparent that there has been no material change in the times of tide in Elk River since the canal was opened. There appears to have been no material change in tidal heights in Back Creek since the opening of the canal.

In Table 10 are given in parallel columns the observed and predicted times and heights of tide at the four canal stations. Times are referred to high water at Reedy Point, and heights, to mean tide level at the same point, 3.48 ft. above the datum.

The predicted values are in fair agreement with the observed values, following them in a general way, and are satisfactory for a preliminary computation. It is believed, however, that the method developed by the author is capable of bringing out closer results. In computing the predicted values, it was necessary to make certain general assumptions as to the conditions that would prevail in the canal. An examination of the discrepancies brought out by a comparison of the observed and predicted results leads to the belief that they can be reduced materially by a revision of the preliminary assumptions.

TABLE 10.—COMPARISON OF OBSERVED AND PREDICTED TIDES IN CHESAPEAKE AND DELAWARE CANAL

Station	HIGH TIDE				LOW TIDE				DURATION, IN HOURS				Range, in feet		Mean tide level, in feet	
	Time, in hours		Height, in feet		Time, in hours		Height, in feet		Rise		Fall

The computations are based on a canal 14 miles long, the length of the excavated portion. The eastern end of the canal connects with the broad estuary of the Delaware River, and such changes in the tidal regimen as may have occurred there are naturally small. At the western end, the connection is with Back Creek, a small tributary of the Elk River. The distance from the Chesapeake City end of the canal through Back Creek to the waters of Elk River is about 4 miles. Back Creek has a width of about 350 ft. at Chesapeake City, gradually increasing to about 1 700 ft. at its mouth; it has a mean depth of about 7 ft. at mean tide level. These dimensions show that this waterway, especially in its upper portion, is of the same order of magnitude as the canal itself. The Elk River, however, is far wider and deeper, forming a body of water so large that it can be expected to maintain its tidal regimen without material change from the comparatively small affect of the canal waters. That this expectation is reasonable is confirmed by the discussion of the changes in tidal times in the vicinity, given previously.

It seems clear that better results can be secured by computing the predictions for a canal 18 miles long than for one of 14 miles, even though this introduces some complications, due to the modifications necessary to take care of the continually changing dimensions in the 4 miles of channel lying in Back Creek.

It is believed preferable to use the observed differences in time of high tide and low tide at the two ends of the canal separately rather than a round value for both. Judging from the lunitidal intervals at Chesapeake City in 1923, and those at Court House Point in 1929, the values at the mouth of Back Creek probably would have been approximately 9.1 hours for high water and 3.1 hours for low water. The probable values at Reedy Point, as shown previously, were 11.1 hours and 5.8 hours, respectively. The differences for the ends of the 18-mile canal are, therefore, 2.0 hours for high water and 2.7 hours for low water.

In the Delaware River, in the vicinity of Reedy Point, the duration of rise of tide is about 1.7 hours less than the duration of fall; but in Elk River, at Court House Point, the difference is only 0.5 hours. In the computed predictions the durations of rise and fall are assumed to be equal at Reedy Point.

For a comparison between observed and predicted velocities in the canal, there are five sets of simultaneous observations at each of the four canal stations. Each set extends over an entire tidal cycle. In Table 11 the mean values of the westerly and easterly velocities, observed and predicted, are shown in parallel columns for each of the canal stations.

The double predictions at Biddle Point (Items Nos. 2 and 3, Column (4)) refer to the sudden change in velocity due to the change in canal cross-section. The values in Item No. 2 pertain to currents between the station and Reedy Point and those in Item No. 3 to currents between the station and Summit.

The relationship of tides and currents in the canal is shown in Fig. 22. Fig. 22(*a*) exhibits the observed tides and currents; and Fig. 22(*b*), the predicted tides and currents.

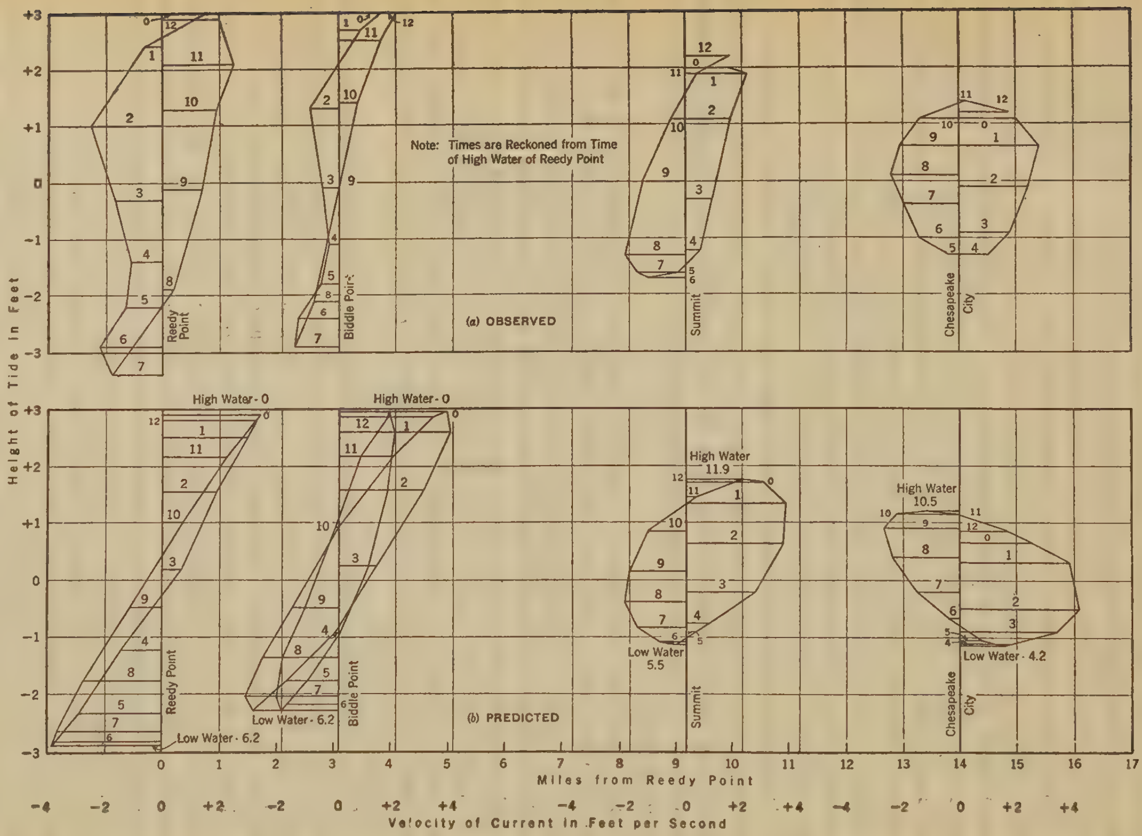

FIG. 22.—HEIGHTS OF TIDE AND VELOCITIES OF CURRENT FOR EACH HOUR (0 to 12), CHESAPEAKE AND DELAWARE CANAL.

The ordinates represent height of tide above and below mean tide level at Reedy Point, and abscissas, the corresponding velocities of current. The numbers on the abscissas indicate the hour after high water at Reedy Point. Plotted in this way, a characteristic curve is formed for each station, bringing out the relations between tidal heights and currents.

TABLE 11.—MEAN VALUES OF WESTERLY AND EASTERLY VELOCITIES

Item No.	Station	Mean Velocity, in Feet per Second			
		Westerly		Easterly	
		Observed	Predicted	Observed	Predicted
(1)	(2)	(3)	(4)	(5)	(6)
1	Reedy Point........	1.5	2.4	1.5	2.4
2	Biddle Point........	1.1	1.2	0.8	1.4
3	Biddle Point........	....	2.4	....	2.1
4	Summit.............	1.2	2.1	1.3	1.4
5	Chesapeake City....	1.9	2.4	1.6	1.7

Comparison of the corresponding diagrams, Fig. 22(*a*) and Fig. 22(*b*), shows how closely the type of tide at each station is brought out by the predictions. The most striking divergence is exhibited at Reedy Point, and is due to local conditions in the canal. Beginning about Mile 1 and extending somewhat beyond Biddle Point, the canal passes through wide marshes, forming basins, with bottom elevations ranging upward from about 1 ft. below half-tide level. These are filled and emptied at each tide through the Delaware River entrance, and the resulting hydraulic currents superimposed on the normal tidal currents are the principal cause of the unusual form of the upper part of the resultant curve at Reedy Point and the somewhat similar appearance of the curve at Biddle Point.

RALPH G. DAVIS,[36] M. AM. SOC. C. E. (by letter).—In this paper, the author has expressed regret that sufficient observations were not available for a close comparison between the theory and the observed tides and currents in the Chesapeake and Delaware Canal. Some observations have been made since those to which the author refers and it is the purpose of this discussion to compare the observations with the results computed by the theory.

Colonel Brown's results are not used for the comparison, as it was found that the canal cross-sections at the time (1928) the observations were made were not uniform and, in some places, gave appreciably different working data. Therefore, in order that a close comparison might be made, the theory has been used and extended to fit the conditions at the time of the observations, and new values have been derived. Additional work has been done on the canal since the preliminary observations (May 13, 1927), which affects the tidal regimen materially; so it seems desirable to include a brief description of the canal as it was at the time the later observations were made.

---

[36] Engr., Beach Erosion Board, Office of Chf. of Engrs., U. S. Army, Washington, D. C.

The channel was dredged with a horizontal bottom to a depth of 12 ft. below mean low water, Delaware River datum. It is 150 ft. wide, from the 12-ft. curve in the Delaware River to a point about 500 ft. west of Reedy Point Bridge (see Fig. 1); 90 ft. wide to the lift bridge at Chesapeake City; and 150 ft. wide in Back Creek, to the 12-ft. curve in Elk River. All side slopes were dredged to 1 ft. vertical on 2 ft. horizontal. As the cut was made through low-lying marsh areas on the eastern end, a high divide near the middle, and in the bed of Back Creek, which varies from 350 to 1 400 ft. in width, the different classes of materials excavated resulted in variations in the depth and width of the completed channel. In some places, considerable overcutting was done to provide for the slides and bulging of the bottom.

FIG. 23.—CHESAPEAKE AND DELAWARE CANAL, SHOWING COMPUTING SECTIONS

Subsequent operations included the dredging of the Delaware City Branch Channel, 6 ft. deep at mean low water and 50 ft. wide on the bottom, from the Delaware River, at Delaware City, to the 12-ft. canal, a distance of about 1¾ miles. The point of junction of the two channels is about 2 miles west of the outer ends of Reedy Point jetties. The Branch Channel was constructed before the current observations were made and preliminary computations indicated that this "by-pass" has a marked influence on the tides and currents throughout the greater part of the canal. The 150-ft. channel at the western end is a component part of the sea-level canal and is affected, to some extent, by the Delaware River tides propagated through the canal. Therefore, this section has been included in the computation for the canal proper.

For the writer's computations, the canal was divided into four sections, exclusive of the Branch Channel, as shown by Fig. 23. Section 1, about 3½ miles in length, includes the 150-ft. channel at the eastern end and the wide waters through the low marshy area. In this section, it was found that the average width at high water is about twice the low-water width, and in the computations, the two widths were handled separately for the positive and negative waves. Section 2 extends from the 3½-mile point through the deep

cut section of the canal to Chesapeake City and is about 10½ miles long. Back Creek was divided into two sections, according to the average widths. Section 3 is about 1⅞ miles long and Section 4, 2 miles in length. The Delaware City Branch Channel, Section 1(*a*), has a reduced depth nearly equal to that for the positive wave of Section 1, and a little greater than one-half the reduced depth for the negative wave, which affects the tides in the main 12-ft. canal considerably. The values for the various sections, as used in the computations, are shown in Table 12.

The relation between the results of the computations and the observed tides and currents is shown graphically on Figs. 24 to 28, inclusive. The observed tide curves (solid lines) represent the average for a long series of tide readings at the five stations indicated. The current curves are averages

for five full tide cycle observations by current meters held in the center of the channel opposite the tide stations and at the six-tenths depth through the entire tide.

Theoretical values agree fairly well for the intermediate stations, the greatest difference occurring in the velocities at the ends. At Reedy Point and Biddle's Point Stations, at the eastern end of the canal, the observed negative velocity curves are somewhat irregular (see Figs. 24 and 25). These irregularities are apparently due to hydraulic phenomena producing alternate siphoning effects at the junction of the two channels. The divergence at the western end is probably due to the difference in the sectional area of Back Creek gauging station and the average area for Section 4, as used in the computations. The comparison demonstrates that the theory is in close agreement with the observations and that it is a practical method for predetermining the tidal heights and velocities in a tidal canal designed to connect two bodies of water, each having an independent tide of its own.

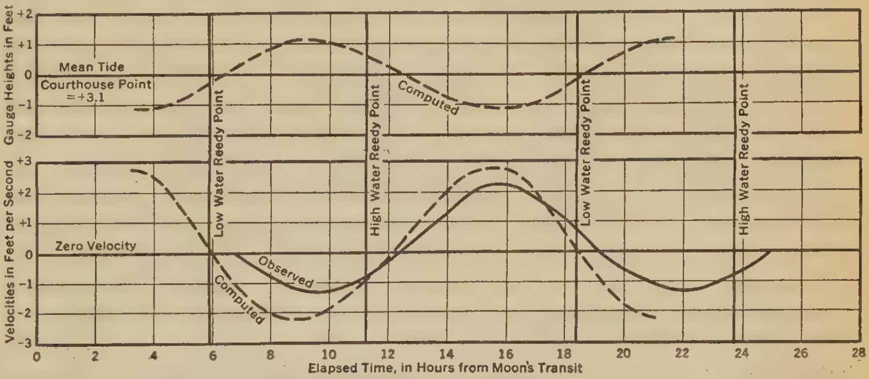

FIG. 28.—COMPARISON OF GAUGE HEIGHTS AND VELOCITIES AT COURTHOUSE POINT (ELK RIVER); 18-MILE STATION

EARL I. BROWN,[37] M. AM. SOC. C. E. (by letter).—In general, the reception which the theory of flow in tidal canals, advanced in the writer's paper, has received, has been quite cordial. No serious differences of opinion have been expressed, and no serious question has been raised as to the soundness of the theory. Mr. Faris and Commander Rude have given some additional information to clarify parts of the paper, but those parts were in connection with statements made to round out the paper, not affecting the fundamentals of the theory.

Commander Rude suggests that the propagation of a wave in a canal that has an outlet into a body of water would continue into the outlet body in its original form, and that it would be dissipated in that body instead of being propagated backward as a reflected wave. It is the writer's view that the wave does continue out into the outlet body, but not in its original amplitude. The amplitude must change in accordance with the law expressed by Equation (37), in which, if l_1 becomes very large or infinite, h_1, the amplitude at the outlet, must be very small or zero. This, of course, is because the canal wave does not possess enough energy to raise a wave in a wider expanse of water to an equal height.

---

[37] Col., Corps of Engrs., U. S. A., U. S. Engr. Office, Philadelphia, Pa.

Commander Rude also declares his understanding that "the hydraulic characteristics of the canal were not taken into consideration by the writer." Apparently, he means that no account is taken of flow under the influence of surface slope. When the two ends of the canal have the same mean level, as is the case in the Chesapeake and Delaware Canal, the only flow that occurs is tidal flow. If there were no tide there would be no current. A discussion is given under the heading, "Insufficiency of Theory That Flow Caused by Surface Slope Accounts for Tidal Flow," to show how a permanent regimen of flow under difference of tidal level at the two ends of the canal can never become established. The slope is constantly variable, and there is never time for such a regimen to become established; hence, there is no such flow. The flow that does exist tends to approach such a regimen, but its velocity is measured by the expression given in either Equation (15) or Equation (50), depending on whether the wave is simple or compound. It is because of the tendency of the current to approach the regimen of flow under the influence of surface slope that makes it possible, as Commander Rude states, to predict currents at the railroad bridge approximately on that assumption. The fact that this can be done at the railroad bridge is a fortuitous chance, however, as it does not follow by any means that it could be done elsewhere in the canal.

Commander Rude expresses a doubt as to whether the writer accepts the "'stationary wave theory' of Harris as an explanation of the changed regimen of the tide in certain bodies of water in which the tide occurs almost simultaneously throughout the entire length of the body * * *."

The "stationary wave" of Harris is nothing more than a resultant wave formed by the interference of two equal and opposed waves (see heading, "Theory of the Interference of Two Opposed Waves"). An illustration of it occurs when a simple wave of translation is propagated into a canal of fairly uniform cross-section, closed at one end, and of length just equal to one-half the wave length. (The positive and negative phases of the ordinary tidal wave are considered as separate waves in this theory.) The canal will then have a stationary wave with a regimen exactly as Harris defines it. Such a wave is known to exist in certain bays such as Long Island Sound, where the western end is almost closed, and in certain seas, where the depth and superficial dimensions bear the proper relationship to the period of the tide for reflections from its shores to interfere with the oncoming wave in the proper phase relationship to create the stationary wave. Harris' theory is, therefore, a special case of the more general theory of reflected waves in interference.

Replying to Commander Rude's inquiry as to Tables 3, 4, and 5, it may be stated that the data in the columns headed, "Bourdelles," are based on observation. Those in columns headed, "Levy," are values computed by Levy according to his formulas.

In commenting on the differences between the Levy formulas as presented by Mr. Parsons, and those of the writer, Mr. Halmos states:

> "The derivation of the [Parsons'] formulas is strictly rational, their application being restricted only by the requirement of comparatively small tidal variations in relation to the depth of the canal."

This restriction, by the requirement of comparatively small tidal variations in relation to the depth of the canal, is sufficient to exclude these formulas from use in most artificial tidal canals constructed for navigation, in which the depth will probably seldom exceed 35 ft., and in which tidal variations of 4 to 5 ft. must be expected. Variations of these magnitudes cannot be considered as small with respect to the depth. In addition to this defect, the writer urges another. The expressions, P and Q, in Equations (2) of the paper[38] by Mr. Parsons, are assumed to be logarithmic functions of x in the formulas, $P = AC^{ax}$, and $Q = BC^{ax}$. It is the writer's opinion that P and Q are not only functions of x, but also of h, which is the quantity sought to be determined. It is the failure of the formulas to include h in the values of P and Q which makes them give equal values for positive and negative waves.

Mr. Halmos suggests that the formulas of the French Academy of Sciences recommended by Mr. Parsons for canals of certain characteristics might have been useful in predicting approximate values of heights and velocities. Their use was rejected by the writer because they are based on the assumptions of a uniform slope of the water surface from end to end of the canal and of the velocity varying with that surface slope, both of which he holds to be erroneous.

The writer admits the difficulty apprehended by Mr. Halmos in finding a proper value of F by the proposed method. Its value for any proposed canal can be estimated with confidence only when it has actually been determined experimentally from existing similar canals.

General Black points out how the useful range of the theory may be extended to the study of the effects of changes projected in the cross-section of tidal canals, and cites the control of current velocities in the East River, at New York City, as an example. The writer may venture further and call attention to the way in which control of these current velocities might be obtained directly by the use of this theory.

The tide in Long Island Sound is of the stationary type due to the reflection of a wave back on itself from the nearly closed western end. The height of the tide increases at a fairly uniform rate from east to west. The depth of the Sound and its length have the required relationship with the tidal period to make the tidal phenomena almost a perfect example of the stationary type of tide. If this relationship were destroyed, the excessive amplitude at the point of reflection near Throgs Neck would be lessened, and this, in turn, would reduce the East River currents. The relationship could be destroyed by making one or more artificial contractions of Long Island Sound at proper intervals in the distance from Fishers Island to

---

[38] "The Cape Cod Canal," by William Barclay Parsons, M. Am. Soc. C. E., *Transactions*, Am. Soc. C. E., Vol. LXXXII (1918), p. 111.

Throgs Neck, breaking up the wave by reflections having a less favorable relationship to cause high amplitudes. A thorough study of this problem by the aid of this theory, it is believed, could lead to a solution giving any desired control of the East River currents.

General Black's hope that similar studies will be made of the tidal action in estuaries such as the Hudson and Delaware Rivers will be realized in the case of the Delaware River. This study is now (1931) in progress.

The readiness with which the effect of changed conditions in the canal are reflected in the results of computations is indicated in the curves given by Messrs. Flynn and Davis. Mr. Flynn showed that a material reduction of discrepancies between observed and computed results could probably be made by a revision of preliminary assumptions to conform more nearly with actual conditions. Mr. Davis has recomputed predicted results under revised assumptions corresponding to actual conditions. The close agreement of his computed and observed results is very gratifying.

THE DON MARTIN PROJECT[1]

By Andrew Weiss,[2] M. Am. Soc. C. E.

With Discussion by Messrs. C. H. Howell, Robert S. Stockton, and Andrew Weiss.

Synopsis

On January 4, 1926, President Plutarco Elias Calles approved the existing Mexican Federal Irrigation Law. It provides in essence that the irrigation of private agricultural lands of whatever kind or extent of cultivation be declared a public interest, if subject to irrigation from Federal sources of water supply. Furthermore, it creates a National Commission of Irrigation composed of three members, to put into effect the studies of irrigation projects, the execution of all plans related thereto, and the administration of these within the provisions of this Act.

This paper gives a general description of the Don Martin Project, one of the largest so far undertaken by the Mexican Government under the provisions of this Act, including therein also a brief outline of the construction methods as well as of the settlement plans in mind and developed to date.

General Features of the Project

Location.—The Don Martin Project is on the Salado River in the States of Coahuila and Nuevo León. The Town of Rodriguez, about 45 miles southwest of Laredo, Tex. (see Fig. 1), is near the center of its irrigable area which embraces a total of 65 000 hectares (160 000 acres).

Irrigation Plan.—The storage feature of this system consists of a reservoir 100 km. (60 miles) directly west of Laredo; its normal capacity is 138 600 hectare-m. (1 123 600 acre-ft.) covering an area of 19 600 hectares (48 412 acres) when filled.

The dam affecting this storage is 66 km. (41 miles) up stream from Rodriguez and an equal distance west of Camaron at a place where a low range of hills known as "Lomerias de Caracol" crosses the Salado River in a general north-northeast and south-southwest direction. This dam will also serve to divert the water impounded by it into the main canal of the system. After leaving the head-works this canal diverges slightly northward from the river for a distance of 42 km. (26 miles) from which point one of its principal branches, the Camaron Lateral, extends in a general easterly direction to cover the first unit to be irrigated in the vicinity of Camaron and Rodriguez. From this point also the main canal turns almost directly south a distance of about 120 km. (75 miles), and about 5 km. (3 miles) up stream from the crossing of the Laredo-Monterrey Highway with the Salado River. (See Fig. 2.) The area to be irrigated covers 30 000 hectares north of the river and 35 000 hectares south of it, or a total of 65 000 hectares (160 000 acres).

FIG. 1.—OUTLINE PLAN SHOWING THE DON MARTIN PROJECT.

In its original concept, the project embraced a much more compact area of which the Town of Camaron formed an approximate central point. Detailed soil investigations revealed the presence of extended tracts of land underlaid with a gypsum subsoil, or a soil which at a depth of about a meter disclosed undesirable strata of crystallized gypsum mixed with highly compacted clays forming a very impermeable structure. For this reason the soil experts selected the younger alluvial soils nearer the river and generally free from these gypsum bottoms. This choice of the major body of the project lands to the south of the river, although resulting in an appreciably higher estimated cost, seems to have been a wise move.

Water Supply.—The water supply for this project is almost wholly dependent upon the storage of flood waters of the Salado River and its upper tributaries, principal of which are the Sabinas and the Nadadores, which unite to form the Salado about 8 km. (5 miles) above the dam. The catchment basin

FIG. 2.—DETAIL PLAN SHOWING DON MARTIN PROJECT.

of this reservoir covers an area of about 30 000 sq. km. (11 500 sq. miles). It is a typical arid region and the major portion of the precipitation comes in the form of torrential rains, generally from June to September, and sometimes in October. From the run-off records, 1901 to 1912, inclusive, and 1923 to date, an annual yield of about 82 000 hectare-m. (670 000 acre-ft.) has been computed. On the basis of an average release of 1¼ m. (4.1 ft.) in depth at the outlet works, this supply is estimated to provide 75 cm., or 2½ ft., of water, over the area contemplated for irrigation, with an estimated conveyance loss of 40 per cent.

The duty of water assumed for these lands is based upon records and systems of agriculture practiced in the Lower Rio Grande Valley, the Imperial Valley, and the Carlsbad Project in New Mexico, which present fairly similar climatic and agricultural conditions.

The project is further favored by the use of an auxiliary equalization storage reservoir in Lake Salinillas, which affords a capacity of about 1 600 hectare-m. (13 000 acre-ft.) at a point 30 km. (19 miles) below the intake.

Surveys and Subdivisions.—When the construction of the project was authorized in October, 1926, there was available a system of topographic maps covering the reservoir site and the part of the project north of the river, sufficiently accurate to give a general idea of the topography and relative geographical dimensions. The extension of the project to the south side called for immediate reconnoissance and preliminary surveys to determine its feasibility and costs. Likewise, an accurate topographic survey of the reservoir site was required to determine more exactly its capacity at various stages.

For topographic control a system of rectangular subdivisions was adopted, similar in all respects to the public surveys in the western part of the United States, modified only to fit the metric system of measure and the relatively restricted area occupied by the project. The system of co-ordinates was based upon an initial point arbitrarily chosen near the geographic center of the project, 8 km. (5 miles) west of Camaron. (See Fig. 2.) From this point ran a base line and a principal meridian, each following the cardinal courses, with range lines running due north and south, 10 km. (6.2 miles) apart at the base, each kilometer being marked by permanent concrete monuments, as were also the initial lines. In like manner a system of parallel east and west township lines was established at 10-km. distances, also marked at each kilometer.

These townships were designated as "Cuadras" and numbered as in the United States. Each "cuadra" was subdivided into twenty-five sections, by section lines having east and west boundaries parallel to the east boundary or range line and thus throwing the deficiencies to the north and the excesses to the south of the base line into the west tier of sections and quarter-sections. No correction lines were established within the project because the confines came wholly or nearly within four tiers of townships, making such refinement unnecessary. This procedure follows the analogous practice in the United States where the Land Office regulations prescribe such correction lines or standard parallels to be established 24 miles apart. Similarly, sections were numbered consecutively from the northeast, Section 5 being at the northwest corner, Section 21 at the southeast corner, and Section 25 at the southwest corner of each cuadra. All interior section lines were marked at each kilometer both as to location and elevation, thereby forming an excellent control for the topography.

This system of subdivision forms also the skeleton upon which is being based the farm unit subdivision, the location of minor distributaries, and the network of secondary roads which will give an outlet to the principal, or market, roads where the topography permits.

In addition, the location of farm units will be greatly facilitated by alphabetical lettering within each section. Thus, Farm Unit A (Cuadra * * *) is in each case the northeast parcel or subdivision within the section, thus distinguishing it from any other parcel within the entire project.

Roads.—The Commission has planned a system of public roads to give easy access to each farm unit. These are to be of such ample width that ultimately a line of shade trees may border each side, to enhance the beauty of the landscape, as was done on the Salt River Project, in Arizona, for example.

FIG. 3.—PLAN OF DAM ACROSS RIO SALADO.

Right of Way.—The entire project is privately owned land. The reservoir site and a large part of the north side is held or controlled by the Bank of Milmo. The remainder is owned by perhaps less than forty persons or associations. Generally speaking, these lands were originally subdivided in lots of about 4 to 8 km. (2½ to 5 miles) in width and 30 km. (18¾ miles), or more, in length, marked by existing fence lines supplemented occasionally by corner monuments. Adjustment has been made for the lands comprised within the first unit. The manner of making these adjustments is further explained under the heading, "Settlement of and Repayment for Lands."

General Description of the Works

Rio Salado Dam—Earth and Gravel Fill.—This dam is a composite structure consisting of an earth and gravel embankment 985 m. (3 231 ft.) in length and a concrete overflow section 234 m. (768 ft.) in length. (See Fig. 3.) Following are the characteristics of the embankment:

	Meters.	Feet.
Length	985	3 231
Greatest height	34.8	114
Up-stream slope	1¾:1	1¾:1
Down-stream slope	2:1	2:1
Width of crown	6	19.7
Free-board to crown of embankment	4	13.1
Free-board to top of parapet wall	5	16.4
Revetment: Reinforced concrete slab varying in thickness from 11 in. at the base to 8 in. at the crown, with ¾-in. round bars, 12 in. center to center, horizontally and vertically.		

The up-stream concrete revetment is constructed as a monolith, anchored to the underlying bed-rock at a depth of from 1 to 6 m. (3 to 20 ft.) Generally, it penetrates the first few layers of loose and seamy rock which are intercalated with seams of clay and soft shale, thereby assuring a reasonably water-tight connection with the foundation rock.

Spillway Section.—The characteristics of this structure are, as follows:

	Meters.	Feet.
Type: Round-head buttress.		
Radius of round-head buttress perpendicular to the axis of the cylinder	6.364	20.9
Width of buttress	9	29.5
Width of contact plane between buttresses	2	6.6
Thickness of buttress walls	2	6.6
Thickness of back-cover slab	0.75	2.5
Maximum height	32	105.0
Elevation, spillway crest (above sea level)	257.38	844.2
Elevation, normal high water in reservoir	261.8	858.7
Elevation, crest of parapet	266.8	875.1
Bridge, width over spillway (clear)	5	16.4
Height of radial gates	4.42	14.5
Width of radial gates	7.62	25.0
Number of radial gates	26	26
Computed discharge capacity with surface elevation of water at 263.8 m. (865.3 ft.)	6 000 cu. m. per sec.	210 000 sec-ft.

The spillway is controlled by a system of twenty-two automatic radial gates, 25 by 14.5 ft., supplemented with four additional gates operated by direct mechanical lift. The water admitted through the 6-in. entrance at the bottom of the float-well exerts a buoyant force on the suspended float sufficient to bring about an overbalancing of the gate frame by action of the suspended counterweight attached to the lever arm which projects 16 ft. beyond the gate axis, as shown in Fig. 4. The admission of the water which effects the filling of the float-well is automatic when the level of the reservoir rises above an elevation of 261.8 m. (858.7 ft.), and, upon cessation of inflow, the float-wells are automatically drained by a 3-in. pipe or orifice at the bottom. The admission of the water may also be regulated at will by a small shutter at the entrance of the 6-in. pipe at spillway level, if for any reason it should be desired to lower any or all of the gates before the water has receded to the normal high-water level, 261.8 m. (858.9 ft.).

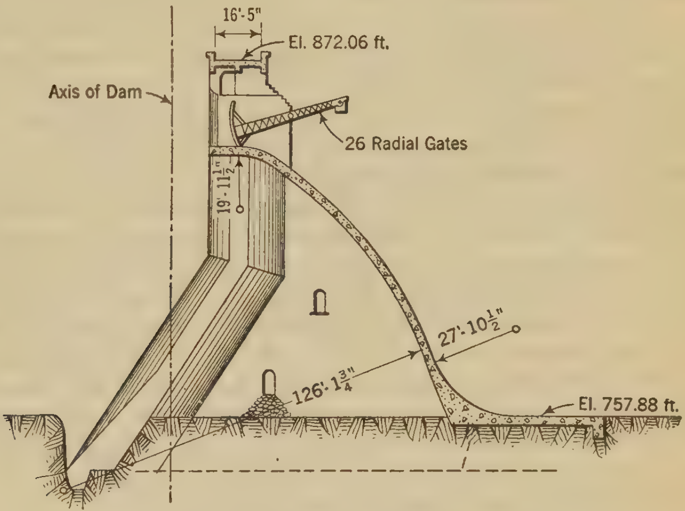

Fig. 4.—Section Through Spillway.

The principle adopted in this automatic control was independently conceived by the designing force of the J. G. White Engineering Corporation. A similar device has been used for some time in the Turlock Irrigation District, the Imperial Valley, in California, and elsewhere, with complete satisfaction.

The type of spillway here adopted follows in general a suggestion given[3] by Fred A. Noetzli, M. Am. Soc. C. E., with modifications to suit local requirements. Its distinctive features are the round-head buttresses conveying the water pressure to the counterforts by radial compression, thus avoiding bending moments and flexural stresses to be resisted by reinforcement. These were considered objectionable because of the highly corrosive action on steel of the waters in this stream. Furthermore, this type of independent units is peculiarly adapted to the local foundation conditions, each of the counterforts being deeply embedded into the limestone strata by a system of channeling, thus affording a maximum attainable sliding resistance within acceptable limits of cost.

Sluice-Gates.—Provision is also made for the complete drainage of the reservoir when desired through four 3.2 by 4-ft. rectangular sluice-gates, operated by geared, hand-lifting devices of suitable design in the interior of the dam at an elevation of 241.26 m. above the floor of the down-stream apron. The gate-sill is at an elevation of 232.1 m., which is somewhat below the ordinary level of the water surface in the river at this point. This gate is shown in Fig. 5.

---

[3] "The Design and Construction of Dams," by Edward Wegmann, M. Am. Soc. C. E., pp. 524-527.

Outlet Works.—Water may be released from the reservoir through two batteries of eight vertical, rectangular, 3.5 by 10-ft. sliding gates, each battery containing four regulating and four emergency gates. (See Fig. 6.) The gate stems extend vertically to mechanical lifting devices operated by electric motors located in a gate-house at the top of the gate tower, at an elevation of 265.8 m. This tower is connected with the dam proper by a steel truss bridge.

The water is released into a 2-bbl. concrete conduit, each barrel built in the form of an elliptic arch of 5.02-m. span (16.7 ft.). The capacity of the gates is in excess of 65 cu. m. per sec. (2 296 sec-ft.), which is the calculated maximum duty of the canal system in its upper reaches.

Dentate Sill.—Adjoining the apron of the dam is a dentate sill of a type similar to the deflectors at the Bull Run Dam constructed for the water supply of the City of Portland, Ore. An excellent discussion of this type, including experiments with models, has been given by B. E. Torpen, M. Am. Soc. C. E.[4] The height from the apron level to its crest will be 2 m. (6½ ft.) and its length over all, measured at right angles to the axis of the dam, 13.22 m. (43.4 ft.). The dentils, or baffle-piers, are alternately sloped up stream 1 on 5 and 1 on 2.5, respectively, as was done on the Bull Run Dam. (See Fig. 7.)

Auxiliary Dike.—About 8 km. (5 miles) south of the dam is a series of connected saddles the aggregate length of which is 9.5 km. (5.9 miles), with minimum depressions extending to an elevation of 257 m. (843 ft.). The characteristics of this dike structure are as follows:

	Meters.	Feet.
Maximum height	8.8	28.9
Up-stream slope	1¾:1	1¾:1
Down-stream slope	2:1	2:1
Width of crown	6.	19.7
Revetment: Mamposteria stone masonry of lime mortar 0.26 m. (10 in.) in thickness, connected at its footing with an up-stream cut-off wall extending to a variable depth, generally 0.8 *H* (*H* representing the height of the dike, in meters).		
Height, parapet wall above crown	1.	3.28
Free-board to top of parapet wall	5	16
Quantity of earth-fill	651 540 cu. m.	852 195 cu. yd.
Quantity of intermediate cut-off trench excavation	38 720 cu. m.	50 645 cu. yd.

The body of this dike is composed of the earth material from shallow borrow-pits near-by and down stream. Because the ground here is underlaid at shallow depths with a gypsum stratum of undesirable composition for this purpose, it has been necessary to limit the depth of the borrow-pits.

FIG. 7.—CROSS-SECTION OF BAFFLE-PIERS.

This canal passes through an auxiliary reservoir with a capacity of 1 600 hectare-m. (12 970 acre-ft.) which will materially aid in the regulation of the system below and the conservation of water during periods of changeable weather and the resulting fluctuating demands.

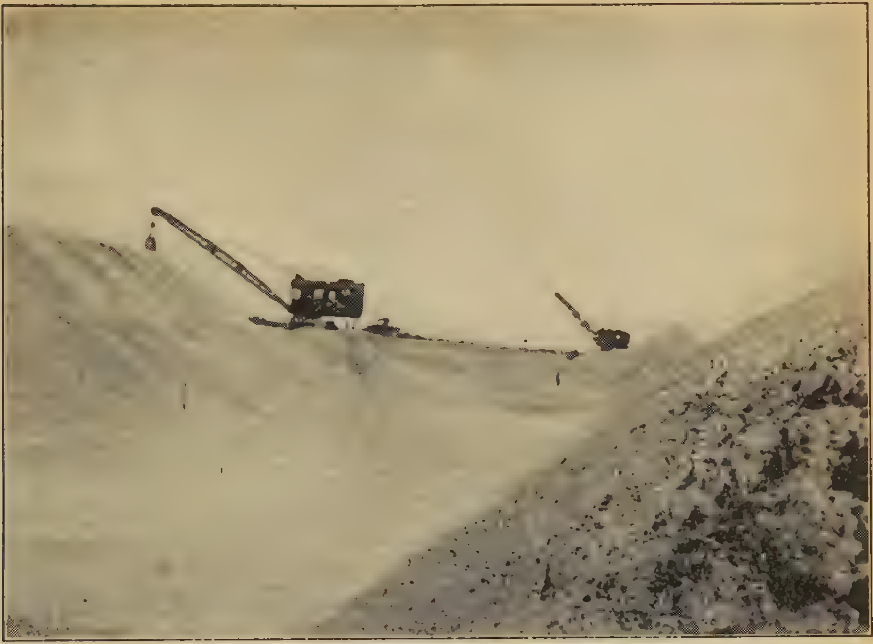

Fig. 8.—View of a Section of the Finished Canal.

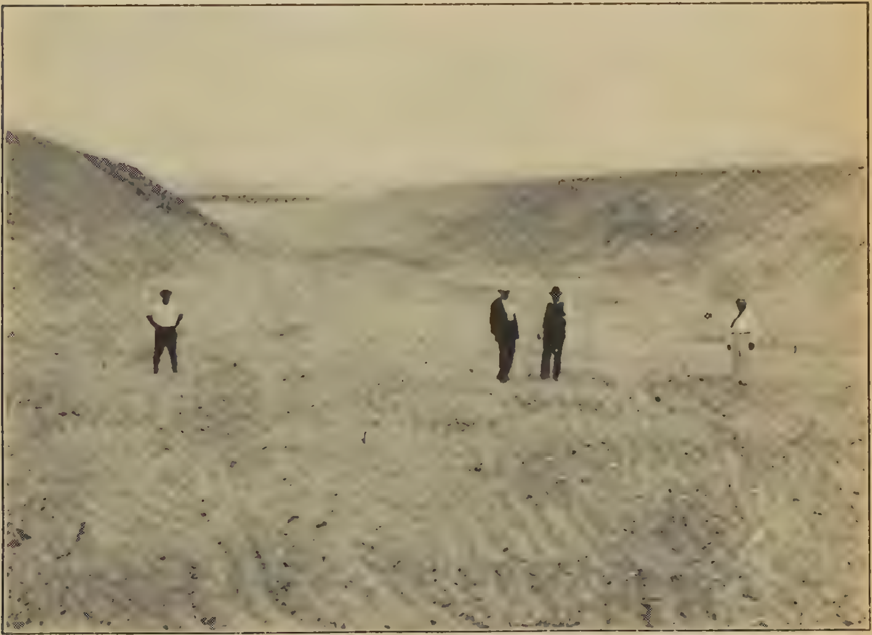

Fig. 9.—View of the 5-Meter Cut in the Main Canal.

This main canal extends to a junction with one of the principal laterals which will supply the first irrigation unit of 40 000 acres, or 16 000 hectares, by means of a suitably designed system of distributaries.

Lateral System.—The lateral system is being planned and built to reach each individual farm unit. The principal (Camaron) lateral serving the first unit of the system, has two branches from which the necessary tributaries are extended in accordance with the best experience, keeping in mind the systems of irrigation which may be adopted. All structures connected with the system are made of a practically permanent type with the exception of the bridges across the principal drainage channels, which for the present are built of timber resting on pile supports. Future developments will best serve to determine which may ultimately best be replaced with more permanent material.

Drainage System.—The principal arteries of the drainage system are planned and built in connection with the irrigation systems. They are constructed of sufficient size and depth so as to provide not only for the safe disposal of the storm and waste waters, but also for the carriage, and more especially the collection, of the soil drainage. As these soils are generally of a fairly compact structure the removal of surplus waters is believed to be essential. Experience on all irrigation projects thus far has demonstrated that this collection can only be made effective by means of relatively deep ditches (7 to 10 ft.) whether the system is of the open or the closed type. In the project area considered, only open drains are built, for the reason that these will have to take care of quantities of storm waters, the volumes of which are known to be large but indeterminate. On account of the uncertainties as to the floods and the extent of future erosion, bridges across drains are being planned of wood with pile supports.

CONSTRUCTION OF WORKS

Early in 1926 the Mexican Government entered into a contract with the J. G. White Engineering Corporation, S. en C., providing for the investigation and construction of a number of irrigation projects in different parts of the Republic. One of these projects, the Rio Mante, near Xicotencatl in the State of Tamaulipas, has been completed and is now in successful operation; another, the Calles Project in the State of Aguascalientes, on the Santiago River, is nearing completion; and the principal irrigation features of the Don Martin Project, including the distributing works for the first irrigation unit of 16 000 hectares (40 000 acres), will be available for the beginning of settlement and irrigation near the end of 1930. The Conchos Project in the State of Chihuahua, which has been given a most exhaustive line of investigation and study, is now (1930) under construction; it covers from 45 000 to 55 000 hectares (112 000 to 137 000 acres) of irrigable area, according to the scheme of development that may be adopted. Other projects in the course of construction and investigation are the Tula, in the State of Hidalgo, and the San Carlos, in the State of Coahuila. These two are old projects which require partial rehabilitation and the extension of the existing works constructed at an earlier date. The irrigation and settlement of the Don Martin Project require the construction and development of the following principal features now (1930) in course of construction or well advanced toward completion in so far as they relate to the first irrigation unit; Rio Salado Dam; Rio Salado Auxiliary Dike; Canal System; Lateral System; Drainage System; and Roads.

Construction Operations

Río Salado Dam.—The length of haul of the material used in the earth and gravel section of the dam was about 2 km. (1¼ miles), and this haulage was effected by a railway system with seven to eight trains, drawn by 20-ton oil-burning locomotives. Each train consisted of from twelve to fourteen 5-yd. dump cars. Cars were loaded by two 2½-yd. steam shovels. Following each successive unloading, 30-h. p. tractors shifted the track a sufficient distance to permit the spreading of the materials, using two 60-h. p. caterpillar tractors and graders. After suitable sprinkling the material was compacted by four 12-ton road rollers in 8-in. layers. It is of ideal composition for a dam embankment of this type, consisting of about 65% of gravel well graded to form a compact mass, mixed with about 35% of "fines". In its compacted state the material weighs approximately 135 lb. per cu. ft.

As is usual in construction of this character, the surface was first stripped of all vegetable matter. Where heavy brush and undergrowth prevailed, the stripping was extended to include the root zone of this undergrowth.

The aggregate for the main body of the concrete overflow section was limestone obtained from the right abutment. Here, an opportunity was afforded for lengthening the spillway and the installing of four additional radial gates of the same size as the twenty-two automatic gates, but operated by direct control. The materials, suitably selected, were passed through a No. 6 gyratory crusher driven by a 240-h.p. Diesel engine of the marine type, the engine also furnishing the motive power for the screens, sand mill, mixers, and auxiliaries. After passing the crusher, the material was elevated 70 ft. to a revolving screen from which it passed into the storage bins used both for supplying the mixer plant below and for loading trucks. A part of the crushed material was returned to a 36-in. cone crusher which furnished the sand for the concrete, no natural sand or gravels having been available. Immediately below the storage bins was the mixing plant, which consisted of two 1-cu. yd. mixers from which the concrete was conveyed to the forms in side dump-cars. (See Figs. 10 and 11.)

The concrete for the outlet works and retaining wall was mixed by a system of from three to four 14 **S** mixers, of ½-yd. capacity. Side dump-cars and chutes were used as for the overflow section.

Auxiliary Dike.—Starting in December, 1927, the construction of the dike progressed uninterruptedly. The major part of the work was performed with three standard 36-in. elevating graders and from eight to twelve 1½-yd. dump wagons to each machine, according to the haul. Because of the shallow soil mantle suitable for this embankment the haul ranged from 55 to 180 m. (180 to 600 ft.). In order to expedite progress and to employ available forces of drivers and light-weight teams, the smaller dike sections were built with slip scrapers and mules. As with the main embankment, the material was spread, leveled in 8-in. layers, wetted, and then rolled with 12-ton road rollers.

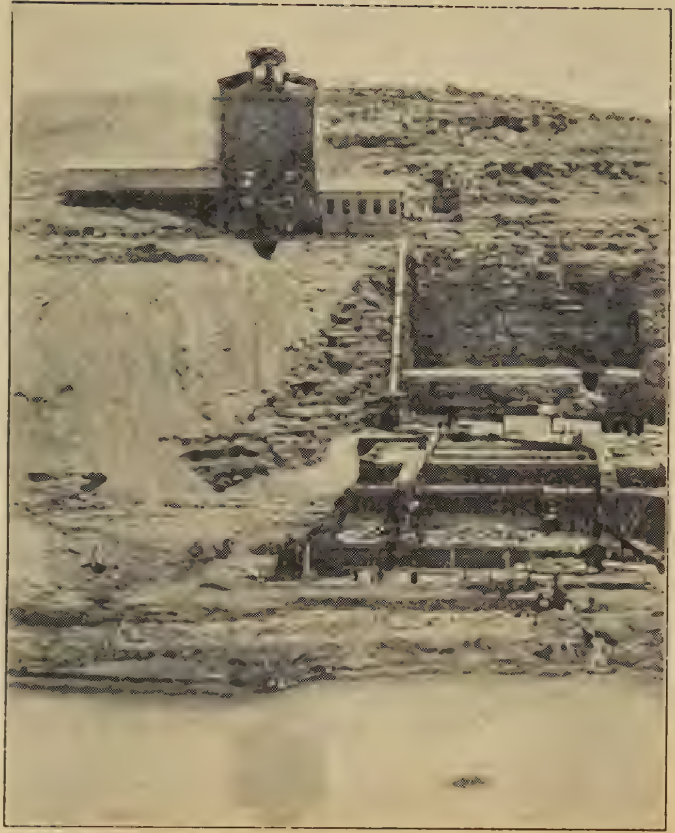

FIG. 10.—VIEW OF THE RIGHT ABUTMENT OF THE SPILLWAY SECTION.

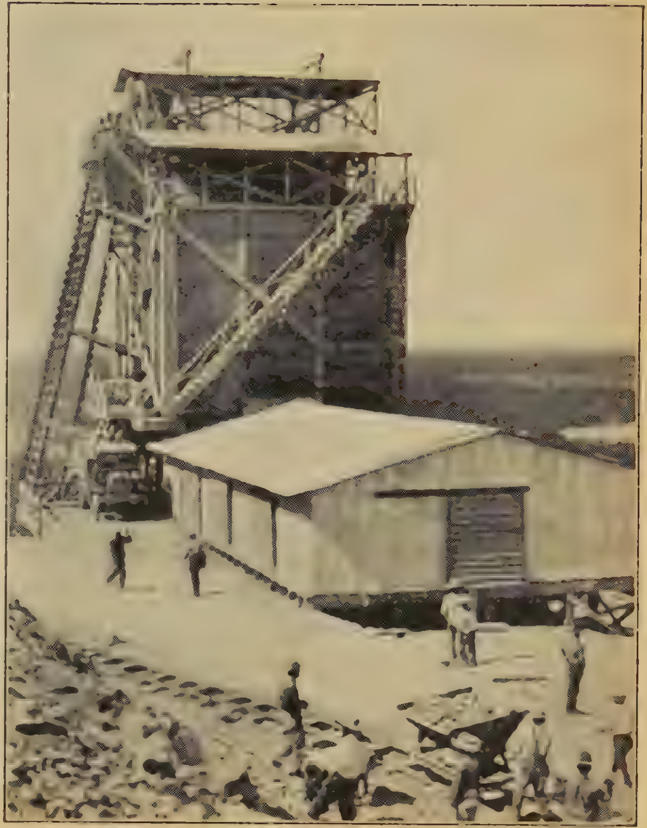

FIG. 11.—VIEW OF THE QUARRY AT THE RIGHT ABUTMENT

Main Canal.—The excavation of the main canal and the stripping of the dam foundation began near the end of March, 1927. Equipment was placed in operation as rapidly as it could be procured from the manufacturers and included fourteen 1½-yd. Diesel and one 2½-yd. Diesel, electric drag-line excavators. Much of the main canal passes through uncommonly difficult ground ranging from mixtures of crystallized gypsum embedded in very compact clays to hard conglomerate rock. It was necessary, therefore, to use large quantities of explosives and a battery of from four to six portable gasoline air compressors supplying the necessary drills and auxiliaries to loosen and shatter these materials. As a result, the usual excavation output was not obtainable, although the operators were nearly all men of long experience and training in such work. Generally speaking, an average output of from 20 000 to 30 000 cu. m. (26 000 to 39 000 cu. yd.) per month was obtained with two 8-hour shifts and using 1½-cu. yd. machines, depending on the materials encountered. Much of the excavation had also to be made in cuts of considerable dimensions for which these machines were inadequate, but owing to the desire of the Commission of Irrigation to limit its equipment to such standard sizes as would be most useful in its expected operations, it was decided to choose only machinery of moderate size such as could be made applicable to future uses.

Lateral System.—In the building of the lateral system, advantage was taken of the excavating equipment on hand. The monthly excavation output was reduced 30% from that on the larger canals of 15 to 40-ft. bottom width and 4 to 8-ft. depth, in similar soils.

Drainage System.—The principal drains for disposing of soil drainage and storm waters are being built jointly with the distributing system and with the same excavating equipment, because of the relatively softer materials encountered. In these, the output and the unit costs have shown more nearly normal results than in the main canal system.

Road System.—Intimately connected with the laying out of the farm unit plan is the provision of an adequate system of public roads. This system as now planned and in process of construction provides for the building of a network of secondary or earth roads giving access to each individual farm unit. This network of secondary roads is united in a number of gravel surfaced roads leading to the principal highways and railroad stations, thereby facilitating marketing and shipments of produce as well as intercommunication with the principal population centers.

SETTLEMENT OF AND RE-PAYMENT FOR LANDS

Land Exchanges.—All the work on the Don Martin Project was under the supervision of the National Commission of Irrigation, created by the Enabling Act of January 4, 1926, to function under the Department of Agriculture and Development. This law provides that, upon the determination of the feasibility of any project composed of private lands, the owner or owners shall be given not to exceed three months within which they may voice their desire to build the necessary works or to co-operate with the Federal Government in such undertakings, under special conditions provided by this Act.

Omitting details, the law further provides that in case the Government builds the work covering private lands, it is to be reimbursed by a part of the owner's holdings such that its assessed unit value in the raw state multiplied by the area ceded to the Government shall be equal to the value of the area retained by the owner multiplied by the unit cost of reclamation or unit values arbitrarily applied. In making these adjustments, the Commission is authorized to add to the assessed value of the raw land in each project, a percentage so that the value of the irrigated land retained by the owner shall be equal to that of the property he possessed before the project was undertaken.

COLONIZATION

Mexican Citizens Favored.—The Commission desires above all things to make available the benefits of these irrigation developments to all Mexican citizens, many of whom live in adjoining States across the border where they have acquired considerable agricultural knowledge and experience. It is hoped that they may form the nucleus of a system of colonists, supplemented by others from within or without the confines of the Republic, the basic thought being to serve best a struggling population which is greatly in need of employment and home resources.

The National Commission of Irrigation has from the outset been conscious of the inherent difficulties attending the settlement of irrigation projects. For this reason every care has been taken to minimize the number of failures. To this end, the preliminary soil surveys upon which the outline of the project was based, were supplemented by a system of detailed soil surveys by competent experts. The precautions thus taken eliminate all doubt as to the adequacy of the soils or the system which is to furnish the water supply.

Following exhaustive studies of the problems of reclamation President Pascual Ortiz Rubio, under date of May 22, 1930, issued in effect the following resolution: That the first unit of the Rio Salado System shall be settled by colonists possessing the following primary requisites: They must be of Mexican nationality, have agricultural experience, be physically and morally capable, and have sufficient capital and resources to establish and support themselves on the land during the first year.

Further, that the Commission will select settlers according to the following preferences: (1) Original land owners within the limits to be colonized; (2) settlers or renters within the region; (3) Mexican farmers, including those outside of Mexican borders desiring to return; (4) Mexicans residing in cities who have the necessary primary qualifications; (5) alumni from the agricultural colleges who have completed their courses; and (6) persons not included within these items, but who have the requisite primary qualifications.

The prices to be paid for the irrigable lands cleared and ready for irrigation are 300 pesos per hectare ($54 50 per acre) for first class; 285 pesos per hectare ($52.00 per acre) for second class; and 270 pesos per hectare ($49.00 per acre) for lands of the third class.[5] To this may be added dry pasture land at the rates of 40, 15, and 7.50 pesos per hectare ($7.30, $2.74, and $1.37

---

[5] The values of 300, 285 and 270 pesos per hectare of irrigable land are based upon going values of similar lands within the Republic, subject to similar soil, climatic, and economic conditions.

per acre), according to classification fixed by the Commission. The colonist is to pay 5% of the cost price on signing the contract, the remainder in not to exceed twenty-five years; and, in addition, the annual operation and maintenance charges necessary for the upkeep of the system and 4% interest on the unpaid instalments.

With the listing of the applications by settlers it became increasingly apparent that a large number of otherwise desirable settlers found it difficult to make the initial payment of 5% of the construction payment, and also to meet the numerous additional items of expenses incident to the first season's operations. To meet this condition the President approved a resolution admitting colonists on a rental basis on a sale contract for a term of three years. The contract provides that the colonist pay the Government an annual rental of 20% of the gross crop returns for the use of the land and the irrigation system; 25% of the gross crop returns for the use of the irrigation system, including the furnishing of the necessary seeds; and 30% of the gross crop returns if the Commission also furnishes the necessary farm equipment, in addition to the seeds and the land as indicated.

It is to be understood that the value of these crops is to be credited to the colonist according to the market prices prevailing (the particular time is probably subject to future regulations by the Commission). Thus, if the value of the colonist's products should amount to 15 pesos per hectare ($2.74 per acre), and the cost of the water charges, including the rental, to 10 pesos per hectare ($1.83 per acre), the colonist is credited with the surplus 5 pesos ($0.91) on the construction charges. In other words, if the renter-colonist who furnishes his own seeds and implements gives his 20% of the gross produce, he is credited with the prevailing market price therefor from which is deducted the fixed charge of 5 pesos per hectare ($0.91 per acre) plus a charge of 50 centavos per 1 000 cu. m. ($0.64 per 100 000 cu. ft.) of water furnished to and measured at the land. Thus, an application of 60 cm. of water (2 ft. in depth) will cause a charge of 5 plus 3 pesos per hectare, making a total of 8 pesos per hectare ($1.46 per acre) to be deducted from his gross returns, the remainder to be credited to the construction charges applying to his lot.

The renter-colonist further obligates himself to cultivate not less than 50% of the irrigable land contained within his lot in a manner subject to the approval of and in accordance with the technical directions given him by the administrators of the local experiment farm. If he fails to accumulate a total of 10% of the value of the construction cost assessed against his land within the term of three years, his contract is then to be cancelled, and such payment benefits as may have accrued will be given to the succeeding settler.

Space does not permit of discussing the details many of which will have to be developed in the future as these and newer problems arise. The general statement gives one an idea of the extent the Mexican Federal Government is disposed to aid reclamation, which attitude appears to be generously supported by the Federal Congress.

The policies thus far pursued by the Presidents of Mexico since and including President Calles and so ably supported by the successive Commissions of

Irrigation are deserving of the highest praise. Without a doubt they will result in a material betterment of internal conditions. This should go far to halt emigration and the consequent neglect of the resources remaining undeveloped within the Republic, especially those relating to agriculture and the supplying of foodstuffs needed by its own people.

Authority and Direction of the Works

All the engineering and construction work described has been performed by the J. G. White Engineering Corporation, S. en C., under contract with the Government of Mexico and in conformity with the policies and general direction of the National Commission of Irrigation appointed by the President.

The original Commission appointed by President Calles was composed of Señores Francisco A. Salido, Director, and Javier Sanchez Mejorada and José Mares. During the administration of President Portes Gil, the Commission was composed of Roberto Gayol, M. Am. Soc. C. E., and Señores Alfonso González Gallardo and González Robles, with Sr. Ignacio López Bancalari as Director General of the Commission.

The present (1930) Commission is composed of Gen. Manuel Perez Treviño, President (who is also Secretary of Agriculture and Development), Sr. Bancalari, Executive Director, and Sr. Leopoldo Vasquez, Secretary-Member of the Commission.

Mr. G. W. Caldwell is General Manager for the J. G. White Engineering Corporation, S. en C., and H. V. R. Thorne, Construction Supervisor, F. E. Weymouth, M. Am. Soc. C. E., was Chief Engineer until March 1, 1929, when he was succeeded by C. H. Howell, M. Am. Soc. C. E., all with offices in the City of Mexico.

The Commission's representatives on the project were Sr. Jesús Oropesa, Technical Supervisor, who was succeeded in April, 1929, by Sr. Manuel Bancalari. R. M. Conner, M. Am. Soc. C. E., is Superintendent of Construction; Sr. A. Becerril Colin was Assistant Superintendent until March, 1930, and the writer, Resident Engineer.

DISCUSSION

C. H. Howell,[6] M. Am. Soc. C. E. (by letter).—The spillway of the Don Martin Dam is the first example of the round-head buttress type to be built. For this reason it may be interesting to give the reasons for its adoption.

Comparative designs were made for gravity, multiple-arch, and flat-slab or Ambursen sections. The foundation is stratified limestone. The strata are almost horizontal. The upper layers are separated by clay and shale seams. A worse condition for sliding can scarcely be imagined.

The gravity section proportioned to care for uplifting with these conditions was found to be exceedingly expensive. The possibility of unequal settlement of the buttresses, due to compression of the seam filling, with the attendant unknown stresses in the arches, eliminated serious consideration of the multiple-arch section. The flat-slab design, of course, was well adapted to meet the uplift and settlement conditions.

However, the round-head type was nearly as efficient as to uplift. Each unit being stable in itself it was equally efficient as to settlement. It required no reinforcing steel as all the material is in compression. There are no thin concrete sections exposed to water pressure. Due to the greater thickness and lower stresses of the up-stream face, a leaner concrete could be used in this portion than would be required for a flat-slab section. Also, due to the greater thickness, the operation of placing concrete is similar to the corresponding operation in a gravity dam. It is much cheaper than placing in the thin sections of the flat-slab design.

The comparative estimates, therefore, showed an appreciable saving in favor of the round-head buttress dam. Furthermore, it was and is considered to be structurally superior in that no tensile or bending stresses are involved.

In regard to uplift on the base of the heads and buttresses the following five conditions were assumed:

Case 1.—No uplift.

Case 2.—Full reservoir head on one-half the area of the buttress head; and full tail-water head on one-half the area of the buttress stem.

Case 3.—Average of full reservoir head and full tail-water head on one-half the area of the buttress head; and full tail-water head on one-half the area of the buttress stem.

Case 4.—Average of full reservoir head and full tail-water head on the entire area of the buttress head; and full tail-water head on the entire area of the buttress stem.

Case 5.—Full reservoir head on the entire area of the buttress head; and full tail-water head on the entire area of the buttress stem.

With the reservoir water surface at Elevation 858.70 (the top of the radial gates), computations indicated sliding coefficients as listed in Table 1 (Items 1 to 6, inclusive).

---

[6] Chf. Engr., J. G. White Eng. Corporation S. en C., City of Mexico, Mexico.

The weight of concrete was assumed at 140 lb. per cu. ft. It actually weighs an average of 142 lb. Tail-water was assumed at Elevation 764. With the water surface at Elevation 865.26, or 6.56 ft. above the top of the radials, the coefficients are as shown in Table 1 (Items 7 to 12, inclusive). Tail-water was assumed at Elevation 770. The weight of the over-pour on the back slab was neglected.

If this dam were to be designed over again, "diamond heads" would be used instead of round heads. The same results are secured with a slight saving in concrete and somewhat easier form work. (See Fig. 12.)

At first, there was some doubt as to the amount of leakage which might occur between the units. There was some fear that it might be large. The reservoir water surface is now (January, 1931) about 10 ft. below the top of the radials. To date, there has been no measurable leakage between the units. The copper seals between them have proved to be practically water-tight. Due to the excellent care used in construction there is no leakage through the horizontal joints between the various concrete lifts. A slight amount of moisture appeared at a few joints when the reservoir began filling, but these places have sealed themselves.

The concrete was approximately a 1:2.5:5 mix, and the coarse aggregate was crushed limestone passing a 3-in. screen. The sand was made of the same material, all of which passed a ¼-in. screen. The water-cement ratio was varied somewhat, but it averaged 1.20. The maximum length of a placement was about 100 ft., and the height of the lifts was 5 ft. The concrete was kept wet—not merely moist but wet—for a minimum of a week. The cement used on the project was manufactured near Monterrey, Mexico.

Practically no shrinkage trouble was experienced on this dam. In fact, practically no shrinkage has been noticed on any concrete placed on the entire project. This is believed to be due mostly to the extra care used in providing somewhat more than the usual quantity of curing water.

In a few of the buttresses hair cracks appeared in the crown of the arches in the lower gallery openings (Fig. 4). These cracks appeared during construction soon after the concrete was placed. They are vertical and are about 6 ft. long. After they were noticed, reinforcing steel was placed over the remaining openings. To date, no other cracks have been found. The existing cracks have not lengthened as the reservoir has filled.

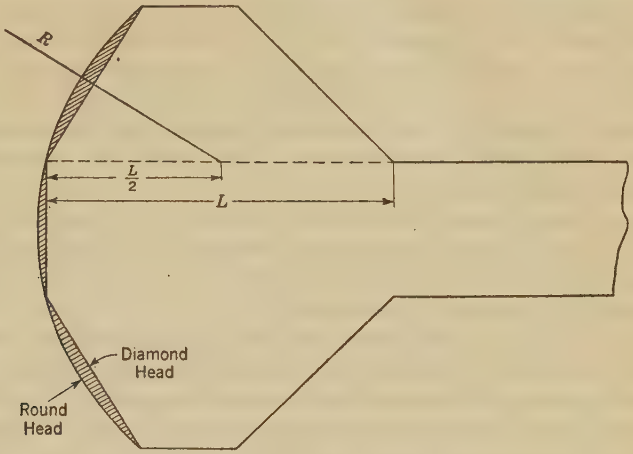

FIG. 12.—COMPARISON OF THE "DIAMOND-HEAD" AND ROUND-HEAD BUTTRESSES.

As stated previously, the water surface in January, 1931, was about 10 ft. below the top of the radial gates. Therefore, actual service conditions had not been reached. However, the automatic action was tested by building a bulkhead in front of one gate and pumping the space between the bulkhead and gate full of water. This reproduced initial starting conditions exactly. Water was then pumped into the float-wells. Movement of the gate took place almost exactly at the computed critical water depth in the float-well. The tests also indicated that an excess of power was available for operation, and that the gates would respond automatically to small changes in the reservoir water surface.

The writer believes that the round-head or diamond-head dam should be considered in all studies for sites where gravity, multiple-arch, or flat-slab sections would be considered. He also believes that the round or diamond-head buttress dam has many inherent merits, and that these will become generally recognized in the future.

ROBERT S. STOCKTON,[7] M. AM. SOC. C. E. (by letter).—The construction and settlement program for the irrigation system described by the author has evidently been planned with full knowledge of the latest ideas and technical information available. The description of the work, while not detailed, indicates the thoroughness and care with which the problems have been studied.

---

[7] Supt. of Operation and Maintenance, Western Section, C. P. Ry. Irrig.-Block, Strathmore, Alberta, Canada.

The exclusion of certain topographically attractive areas from irrigation development on account of alkaline subsoil conditions, is most wise, and while this increases the first cost of the system the future average cost of operation and maintenance will probably be much less than it would otherwise have been. The great gain, however, will be in reducing the loss in capital investment due to lands becoming worthless from accumulation of alkaline salts. Even a drainage system as carefully planned as has been done for the Don Martin Project, will not completely protect lands with subsoil heavily impregnated with alkali, and the costs of protection or reclamation are quite likely to be prohibitive.

Stated in another way, the plans for building an irrigation system and settling the lands should include consideration of the probable condition after many years of operation and should provide, as far as possible, for the permanency of profitable production.

All those who are experienced in irrigation development are aware of the difficulty of obtaining settlers who will be able to put the lands on a productive basis before the interest and carrying charges have mounted to a point where it is no longer possible to collect them. While Governments can afford to take some loss on the ground that, in the end, an increased population and production will accrue, the plans should provide, as far as can be foreseen, for the repayment of all costs, including a low rate of interest. In most cases the development should be deferred or abandoned if it can not "pay out" on a strictly business basis.

Another point, that is most essential, is that of supervision of the farm program of the first settlers. Mr. Weiss mentions that such supervision is to be provided for all settlers on the three-year rental basis. It may probably occur that for good settlers it will be found desirable to extend the rental period to, say, five years.

The matter of proper supervision and layout of the farm management and cropping system is so important that it would be well if all land and water contracts included a definite agreement, by which the settler would be obligated to follow the directions of the farm manager or agriculturist responsible for results, for a period of five years, or until a substantial equity in the holding had been established.

It is essential of course that the agricultural supervisor shall be experienced and thoroughly qualified in every way. He should have a personality sufficiently forceful and diplomatic to obtain results with a minimum amount of friction.

Some credit for the purchase of stock and equipment is most desirable, after the character of the settler has been demonstrated as worthy, and the management has been tested as to its soundness. If funds are made available, they should be handled through a bank and by strictly business methods, as this is the point at which mistakes are most easily made, but where good management will hasten and enhance prosperity.

ANDREW WEISS,[8] M. AM. SOC. C. E. (by letter).—The writer is indebted to Mr. Howell for the pertinent explanatory comments, stating more fully the reasons for the adoption of the buttress type of dam.

To date (1931) only two of the contact joints between the buttresses have shown leakage and this in negligible quantities. As the water was being raised within the reservoir, some leakages developed in varying amounts through the limestone seams around the south abutment, and these were effectually followed by drilling and grouting. At this writing, the reservoir is filled to within 3 ft. of the flowage line.

The automatic opening feature on all the radial gates was further tested, with satisfactory results, by pumping water into the float-wells, but incident to these operations a number of unforeseen details were discovered, which led to the adoption of certain further precautionary measures. One of these was the use of covers for the tubes admitting water to the float chambers, thus preventing careless or mischievous introduction of waste matter and obstacles. Some of the chains designed to connect the gates with the movable emergency lifting devices had become loosened from the upper corners of the gates and, with the automatic lift in operation, the suction of the escaping water had a tendency to drag the slack portion of these chains between the radial gate seats and the rubber seals, thus interfering with free movement. Hence, it was necessary to be certain of the locking of these latches which fasten the chains to the upper corners of the gates in order to avoid a recurrence of these happenings (see Fig. 13).

A view of the overflow section, looking up stream from the south end, is shown in Fig. 14. Fig. 15 shows the discharge of three gates under a 9-ft. head, each releasing about 2 200 cu. ft. per sec. It will be seen that immediately at the toe of the dam some spray and a turbulent wave action are formed; the latter, however, gradually reduces to a steady or normal flow condition about 20 ft. down stream from the dentated sill. With such quantities of water as have been released it is too soon to state how effective these dentated sills may be, but it appears that erosion below the toe will be kept entirely within harmless limits.

Mr. Stockton correctly points out the difficulties of obtaining settlers of the required financial capacity and training in agricultural pursuits, who will be able to put the lands on a productive basis before the interest and carrying charges have mounted to a point where it is no longer possible to collect them. This applies with particular emphasis to the new projects being built by the Mexican Federal Commission of Reclamation because of the greater scarcity of settlers with the requisite means. For this purpose the framers of the reclamation policy and the regulations expressing it, have wisely provided for three-year rental contracts and for farm supervision. It is too soon to predict the extent to which this supervision may be carried, but judging from the interest thus far displayed by the governmental authorities in charge, it is believed that such assistance will be freely provided and that the settlers will co-operate in a most responsive spirit.

Beginning with the very initiation of these reclamation schemes the original Commission and its successors in charge have given the most detailed study to the reclamation problems in the United States and elsewhere, and have familiarized themselves with the principal results of the many investigations during the course of development—more especially with the report of the Fact-Finding Commission—to the end that errors might be minimized. One of the outgrowths of this study was the conclusion that most of these projects could not be undertaken without some form of subsidy from the Federal Treasury and, for this reason, it was decided to fix the construction charges commensurately with the market value of the land in question. Doubtless much will have to be added to the present regulations as experience and economic developments may dictate within the coming years. It can not be over-emphasized, however, that the definite fixing of the construction charges corresponding to the market values of the land rather than reclamation costs has obviated much of the criticisms and incentives for attack on the Mexican Federal Commission on Reclamation and its engineers such as was practiced in the United States with the beginning of the repayments. This train of events was pointed out exceedingly well by the late F. H. Newell, M. Am. Soc. C. E., in his discussion of "Some Phases of Irrigation Finance."[9]

Mr. Stockton correctly indicates the importance of proper supervision and layout of farm management and that such be continued until a substantial equity in the holding has been established. In this case the regulations provide that the settler follow the general guidance of the farm advisers and the experiment station, from which sources it is believed much good will result. Much misunderstanding has existed as to the proper functions, responsibilities, and results of agricultural advisers on these projects. It is pointed out with reason that no one man can combine the necessary experience and training to direct the farming operations of all the settlers. This is not and should not be expected. His functions and work are more nearly comparable with that of the field men as they are employed and directed by the sugar companies operating in the Western States. Few of these men would qualify as master farmers. They do fill an important need, however, as general advisers and as purveyors of information as well as keepers of statistical data relating to the needs and the prospects of the individual settlers. These data may furnish a reliable basis for the future credits and assistances that should be provided by the Government, or by other credit agencies.

Such a system, if properly managed and maintained, will in no sense impair the settler's individuality and self-reliance, as it is essentially co-operative and helpful. It is obviously unpopular with a certain minority of settlers and sympathizers who are chiefly interested in building and collecting pretexts and arguments in defense of non-payment and non-performance of just and practicable dues; but this fact does not argue against such a system of vigilance and help because the majority of the settlers on any project are essentially as honest and as anxious to meet their debts as they become due, as people are in other walks of life. Experience has shown that such a system of supervision soon becomes popular rather than otherwise if backed by the proper management and ideals.

A DISCHARGE DIAGRAM FOR UNIFORM FLOW IN OPEN CHANNELS[1]

By Murray Blanchard,[2] M. Am. Soc. C. E.

With Discussion by Messrs. Lynn Perry, J. B. Macphail, G. B. Pillsbury, Lynn Crandall, Benjamin E. Jones, A. J. Matheson, L. Standish Hall, Ray E. Mackenzie, and Murray Blanchard.

Synopsis

This paper introduces a diagram of discharge stage and slope or fall relation for uniform flow in open channels. It is based on the Chezy formula wherein, for a constant stage, the discharge varies as the square root of the slope or fall and is designed to give the discharges at any stage for the falls that create the resulting discharges.

A discharge diagram consists of a series of fall curves referred to discharges as abscissas and stages as ordinates, from which the discharge for any observed stage and fall can be obtained.

The development of the diagram is shown by a practical application to a series of discharge measurements made in 1914-16 on the Chicago Sanitary District Canal with regulated flows in a uniform rock section.

Discharge diagrams are applicable to all uniform stream flows, whereas the ordinary discharge curve cannot be used where there is back-water effect or where the up-stream and down-stream waters do not rise or fall simultaneously.

The Discharge or Rating Curve

In many streams for uniform flow there is only one stage and a corresponding slope for any discharge in a reach between stations so spaced that the water-surface profile is a straight line. An increase in the discharge creates a higher stage with its corresponding slope. Increments of discharge have their accompanying increments of stage in such a manner that by plotting discharges as abscissas and corresponding stages as ordinates, the points will fall in a regular curve. This is the ordinary discharge curve shown in Fig. 1. The profiles that obtain at the various stages are of the type shown in Fig. 2.

---

[1] Published in January, 1931, *Proceedings*.

[2] Cons. Engr., Chicago, Ill.

They do not cross one another, are nearly parallel, and are approximately parallel to the bed of the stream.

Sometimes, it is necessary to make measurements of discharge when the flow is not uniform; that is, while the stage is rising or falling. Discharges thus obtained will fall, respectively, to the right or left of the curve for uniform flow, and methods have been devised for reducing these discharges to their positions on the discharge curve, in the directions indicated in Fig. 3.

When the Discharge Curve Is not Applicable

There are streams in which the flow is varied by inflow and outflow such that, at any stage, a wide range of discharges may obtain. This may be due to various conditions, such as:

(*a*) The back-water effect of high, low, or intermediate stages of the receiving reservoir (river, lake, or pool).
(*b*) The effect of a large tributary inflow.
(*c*) The effect of high, low, or intermediate stages of an up-stream reservoir (lake or pool).

* Report of Chf. of Engrs., U. S. A., for 1902, Appendix EEE, pp. 2867–2872; and for 1903 Appendix EEE, pp. 2813–2817.

† "Hydraulics of Chicago Sanitary District's Main Channel," *Journal*, Western Soc. of Engrs., September, 1920, and discussion, August, 1921.

The instances listed in Table 1 are illustrated graphically in the profiles of Type *B*, Fig. 4. In the reach, *A-B*, the upper profiles have a common mean elevation of water surface and the lower profiles have another common mean stage.

In making a study and investigation of flood flows of the Illinois River in 1929, these conditions were encountered. It was found that at all the gauging stations in the lower 100 miles of the river, discharges that had been measured by competent observers under the direction of most reliable authorities, would appear to be grossly in error when compared with the values indicated by established discharge curves.

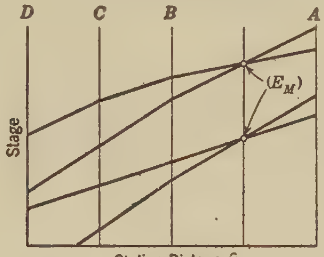

FIG. 4.—PROFILES, TYPE *B*.

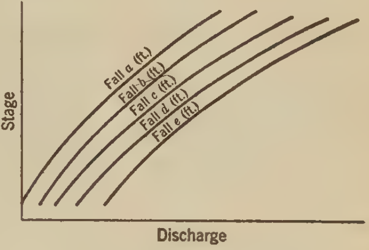

FIG. 5.—TYPICAL DISCHARGE DIAGRAM.

To obtain a substitute for the rating curve under these conditions the writer developed the discharge diagram described herein. It consists of a series of curves of slope which are referred to discharge and stage and from which the discharge can be obtained for a known stage and slope, or fall (see Fig. 5).

DEVELOPMENT OF THE DISCHARGE DIAGRAM

Consider, first, a reach in which the slope is unbroken, and a certain mean stage of reach. The Chezy formula for discharge, *Q*, in terms of mean area of section, *A*, mean hydraulic radius, *R*, and slope, *S*, is:

$$Q = A\ C\ R^{\frac{1}{2}}\ S^{\frac{1}{2}} = \frac{A\ C\ R^{\frac{1}{2}}\ F^{\frac{1}{2}}}{L^{\frac{1}{2}}} \qquad \text{(1)}$$

in which, *C* is a constant and the slope, *S*, is equal to the fall, *F*, divided by the length of reach, *L*. For a single stage under consideration the factors, (*A*), (*C*), (*R*), and (*L*), are constant. Therefore, *K* may be substituted in Equation (1) for the quantity, $\frac{A\ C\ R^{\frac{1}{2}}}{L^{\frac{1}{2}}}$, so that Equation (1) becomes,

$$Q = K\ F^{\frac{1}{2}} \qquad \text{(2)}$$

For any other discharge and corresponding fall (denoted by the subscripts, *x*),

$$Q_x = K\ F_x^{\frac{1}{2}} \qquad \text{(3)}$$

From Equations (2) and (3), $\frac{Q_x}{Q} = \frac{F_x^{\frac{1}{2}}}{F^{\frac{1}{2}}}$,

or,

$$Q_x = Q\ \frac{(F_x^{\frac{1}{2}})}{(F^{\frac{1}{2}})} \qquad \text{(4)}$$

and,

$$F_x = F\left(\frac{Q_x}{Q}\right)^2 \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (5)$$

The method of obtaining a discharge diagram from these formulas may be described in ten steps, as follows:

1.—Decide upon a base discharge (preferably about an average) to which all observations are to be reduced.

TABLE 2.—SAMPLE COMPUTATIONS REQUIRED FOR CONSTRUCTING DISCHARGE DIAGRAM FOR EQUATION (5)

Group No.	Observation No.	STAGE (ALL MINUS)			DISCHARGE	FALL		DISCHARGE

	160	1.26	1.86	1.56	8 250	0.60	0.57	....	....	....
E				1.54	7 860	0.55	0.57	7 700	−160	2.1

2.—From each discharge and corresponding fall, using Equation (5), compute the fall corresponding to the base discharge. This step is demonstrated briefly in Table 2 for a number of observations made on the Chicago Drainage Canal in 1914, 1915, and 1916.

3.—Compute the average elevation of the reach for each observation.

4.—Plot the falls as abscissas with the corresponding average stages as ordinates.

5.—Pass an average smooth curve through the points thus obtained and call it the base curve.

6.—From the base curve, take off the fall for the base discharge at desired stage intervals.

7.—By means of Equation (4) compute the discharge corresponding to a desired slope at each of the stage intervals.

8.—Compute the discharges corresponding to other desired falls, F_x, at each of the stage intervals.

9.—At the stage intervals plot the discharges as abscissas and the corresponding falls as ordinates.

10.—Join the points of the same slope value, and smooth slope curves will be obtained.

Fig. 6 in an example of a discharge diagram constructed from actual observations made on the Chicago Drainage Canal, some of which data are given in Table 2. The series of slope curves form the discharge diagram (see Fig. 7).

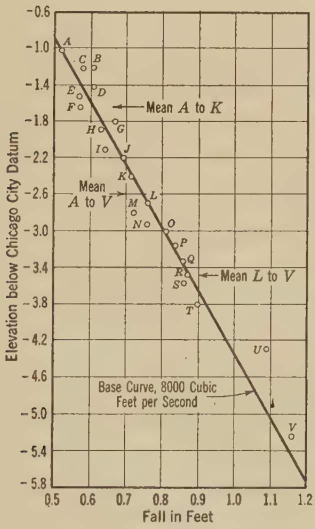

FIG. 6.—BASE DISCHARGE CURVE.

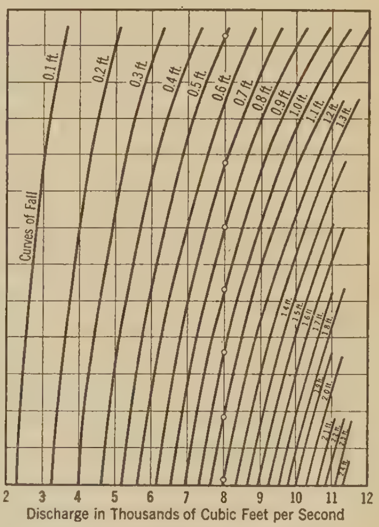

FIG. 7.—DISCHARGE DIAGRAM.

Since a stage at one end of a reach in connection with any certain slope or fall corresponds to a definite discharge, a diagram of discharge, an end-station stage, and a slope or fall relation can be constructed in a manner similar to that for the diagram of discharge, mean stage, and slope, or fall relation, herein described.

CONCLUSIONS

The construction of a discharge diagram involves the additional expense, over the discharge curve, of maintaining and reading two gauges in each reach instead of one. It would seem that in most cases the more reliable results obtained from the former would warrant the expenditure.

Even if the diagram is constructed for all cases of uniform flow there would also be the special uses for the discharge curve, which gives for any stage the discharge that normally or most frequently occurs. It is often desirable to know the increment of normal discharge for a rise or fall in stage. Thus, the increment of discharge in the outlet of a large lake, taking into account also the effect of evaporation, etc., is a measure of the effect of withdrawal from the lake of a volume equivalent to the increment.

DISCUSSION

Lynn Perry,[3] M. Am. Soc. C. E. (by letter).—The author is to be commended and congratulated for the work he has done in connection with this paper. It is manifest that a great deal of careful thought has been given to a problem that has confronted many engineers who have been identified with the gauging of streams.

The Chezy formula (Equation (1)), seems to be in more common use than any other, and when the coefficient is carefully chosen it is probably as accurate as any that has been proposed. However, it is based on assumptions that do not usually obtain in an unregulated stream flowing naturally. Reference is made particularly to the mean hydraulic radius, R, and the slope, S. The writer has had some experiences that have tended to destroy the usual simple faith in Kutter's value for C.

The mean hydraulic radius varies with the stages of a stream at the particular point of observation. An identical value for R may be obtained for, say, an increased depth of the water at the observation point: (*a*) When the increased depth is caused by back-water; and (*b*) when it is caused by a flood flow in the stream. It should be perfectly obvious that such conditions are not logical. It may be argued that the slope, S, would be different in a case of this kind and that this difference will cause the Chezy formula to show the proper difference in discharge. This may be answered in two ways: (1) Actual observations, limited to the writer's experience, indicate that the difference in the slope, S, does not account for the difference in the actual measured discharge; and (2) R is not a constant and should not be so treated.

This formula (Equation (1)) was proposed by Chezy in 1775 following a series of observations of stream flow. Notwithstanding the fact that it is purely empirical, hydraulic engineers have used it, almost unchanged and unquestioned, during 150 years of the most extensive engineering activity since the dawn of history. Scores of engineers have lived during every generation subsequent to the time of Chezy, who are devoting more time, with more ably trained assistants, with more accurate instruments, and working on many more streams than Chezy. It certainly does seem to the writer that some engineer engaged in stream measurement and one who has at his disposal a large amount of data and some personnel, should have the initiative and courage to propose a more accurate and at the same time as economical and practical a method of measuring stream flow as Chezy.

When two observations are made in order to obtain a correct value for S at the time of reading the stage, a much more accurate value for the discharge can be computed than when the stage alone is read. The author refers to the additional expense of making the additional observation. Of course, where there is only one observation point on a stream, the expense would be doubled. Most of the large and important streams in the United States have a number of such points where the stage is read and reported every day. The writer believes that these rivers could be organized in such a way that the additional expense would be relatively small. Even if the cost is somewhat more per observation point, would it not be far better to have a smaller number of more accurate observations than a larger number of less trustworthy ones?

---

[3] Asst. Prof., Hydr. and San. Eng., Lafayette Coll., Easton, Pa.

The author does not state whether he is making use of the well known and frequently used Kutter formula for C. When Kutter first proposed his formula for the computation of C in the Chezy formula, he did not include S; that is, his own personal observations did not indicate to him that the slope would have any effect on the constant, C. Afterward, when reports of the flow of the Mississippi River were published by Humphreys and Abbot,[4] he was prevailed upon to alter his formula to absorb certain variations that could be taken care of by admitting that the slope had some influence on the numerical value of C in individual cases. If the Kutter formula is used, the author's expression for his constant, K, in Equation (2), will not be a constant. This must be obvious because the slope,

$$\frac{F^{\frac{1}{2}}}{L^{\frac{1}{2}}} = S \dots\dots\dots\dots\dots\dots\dots\dots (6)$$

is also to be included in C.

Assuming that the author has used some other more accurate and more reliable method for obtaining the coefficient, C, and that, therefore, his Equation (2) is correct; and if F is the total fall, in feet, in the run, L, in feet, so that Equation (6) is correct, then the value for K, as given by the author, is also correct, namely,

$$K = \frac{A\ C\ R^{\frac{1}{2}}}{L^{\frac{1}{2}}} \dots\dots\dots\dots\dots\dots\dots\dots (7)$$

in which, A is the area of the cross-section of the stream, in square feet; R, the mean hydraulic radius, in feet; and C complies with the requirements of the foregoing paragraph.

If Equation (7) is a true constant for all values of Q which the range of the observations is to cover, Equation (2) is a true parabola. Now, if this is plotted on logarithmic cross-section paper, it will be a right line; the position and direction will be fixed by the numerical values of K and the exponent of F, respectively. The numerical value of K is the point where the line intercepts the Y-axis and the exponent of F $(= + \frac{1}{2})$ is the slope of the line.

A considerable number of engineers who have had some experience in measuring the flow of water will refuse to grant that V (and, consequently, Q) varies as the square root of S. The results of much work along this line have been published.

Table 2 does not give the numerical values for A, C, R or L, but values for Q and F are given for a number of cases. Taking Group A as an example, $Q = 9\,300$, $F = 0.70$; therefore, $K = 11\,000$. Taking a sheet of logarithmic cross-section paper and plotting values of F along the horizontal scale and Q

---

[4] Report upon the Physics and Hydraulics of the Mississippi River, by A. A. Humphreys and H. S. Abbot, *Professional Papers*, Corps of Topographical Engrs., U. S. Army, No. 4, 1861.

vertically, the solid line on Fig. 8 can be obtained. Readings from this line will give values for Q corresponding to observed values for F as long as other factors are constant. With an increase in the stage reading, raising K, say, to 13 000, the first line above is obtained; with a decrease to 9 000, the line below, etc. A chart of this type appears to be much more direct and of much simpler construction than that proposed by the author.

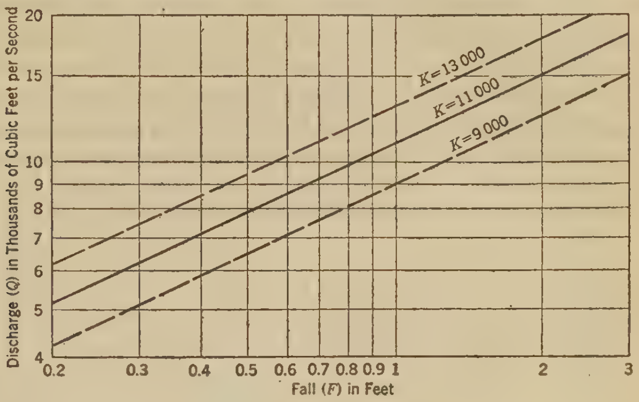

FIG. 8.

If, however, Mr. Blanchard prefers to use the ratio of the square roots of the fall as abscissas, it is necessary only to consider his Equation (5) which reduces to,

$$Q_x = Q \frac{F_x^{\frac{1}{2}}}{F^{\frac{1}{2}}} \qquad \text{.........................(8)}$$

Then, his base, Q, becomes the Y-intercept value, and the ratio of the square roots of the new fall to the base fall is the ordinates.

J. B. MACPHAIL,[5] ASSOC. M. AM. SOC. C. E. (by letter).—A slight simplification can be made in Mr. Blanchard's method. The coefficient, K, is a function of the physical dimensions of the reach at the stage under consideration. It varies with the mean elevation of the water surface of the reach, and a curve, therefore, can be plotted, giving the value of K for any given mean elevation.

Hence, this curve can be used with Equation (2) to plot the curves in Fig. 7. It has, however, a greater curvature than the base discharge curve proposed and, therefore, it may be less precisely definable in some cases in which experimental difficulties introduce noticeable residual errors.

G. B. PILLSBURY,[6] M. AM. SOC. C. E. (by letter).—In this paper the author points out that the discharge of a stream at a given gauging station is not necessarily a function of the river stage at that station alone, but may depend also on the river stage at a station down stream. Such a condition will occur in fact if the back-water effect of the lower station extends to the upper station, and the stage at the lower station does not result wholly from the discharge passing the upper one. It is a condition frequently arising, particularly in large rivers.

---

[5] With Power Eng. Co., Montreal, Que., Canada.

[6] Brig.-Gen., U. S. A.; Asst. Chf. of Engrs., U. S. A., Washington, D. C.

The author bases his deduction on the premise that the discharge varies with the square root of the fall between the two stations, and with a function of the arithmetical mean of the stages at the two stations. While he derives this premise from the Chezy formula, it might be based as well on the general law that the discharge in an open channel varies as the square root of the slope and as a function of the hydraulic radius, the latter, in turn, being a direct function of the river stage. If two stations are sufficiently contiguous, the slope at both will vary directly with the fall between them, and the discharge will vary as the square root of the fall. This condition will obtain, however, only when the fall between the stations is small in comparison with the river depth.

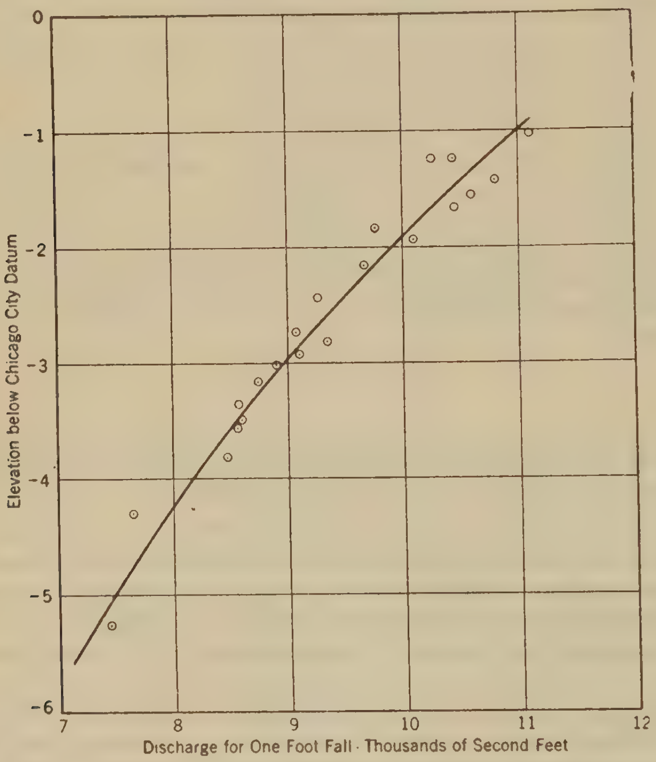

FIG. 9.

If sufficient data are available on the flow with a wide variation in fall with respect to the stage, it may be possible to derive a weighted mean of the upper and lower gauges which will afford a better measure of the equivalent hydraulic radius of the section than the arithmetical mean. In the usual case, however, the data are insufficient to justify anything but the arithmetical mean.

A diagram in the form presented by the author appears, therefore, to be based on correct hydraulic principles. The preparation of such a diagram is, however, quite a laborious procedure, and the taking off of discharge from the diagram involves estimation of proportionate intervals. A much simpler procedure is the construction of a discharge diagram for 1-ft. fall between the two stations. This diagram is used like any other discharge diagram, except that its readings are multiplied by the square root of the fall for which the discharge is desired—a very simple, slide-rule operation.

To construct such a diagram, each observed discharge is divided by the square root of the fall, and the quotient is plotted against the mean of the corresponding stages. Such a diagram, prepared from the author's data, is demonstrated in Fig. 9.

LYNN CRANDALL,[7] M. AM. SOC. C. E. (by letter).—The writer has been interested in this paper because of his experience in making discharge determinations under conditions somewhat similar to those described by the author. About 1916 he developed practically the same procedure in determining discharges on large irrigation canals in Idaho where the stage-discharge relation was affected by the operation of check-gates in the canal some distance below the measuring station. For convenience, however, the stage-fall-discharge diagrams were referred to one of the gauges only, instead of to the mean elevation between gauges as was done by the author.

The general method suggested by Mr. Blanchard, in various similar and modified forms, has been used to the writer's knowledge by many engineers in computing discharges under conditions of variable slope, and it is a valuable aid where such conditions obtain. Attention should be directed, however, to the fact that the method as outlined is applicable only to conditions where the channel cross-section and coefficient of roughness remain unchanged.

The usual stage-discharge rating curve may be affected at any time, not only by changes in slope but, also, by changes in the cross-section of the stream, or in the coefficient of roughness which, on many Western streams, results from the growth of moss and aquatic vegetation at certain seasons of the year.

The effect on the standard rating curve, at any station, of changes in cross-section or degree of roughness of the stream channel, can be determined effectively only by making current-meter measurements, and at stations of variable rating where accurate records are desired there is no general substitute for current-meter measurements carefully made at fairly frequent intervals.

If the standard rating curve is changed at any station, due to cutting or filling of the channel or to the growth of aquatic vegetation, the new rating curve will usually be approximately parallel in gauge height to the old curve over a considerable range of stage. Advantage may be taken of this fact to extend the use of the stage-fall-discharge diagram also to stations the ratings of which are affected by channel changes or growth of aquatic vegetation, in addition to the effect of variable slopes in the water surface at given stages resulting from back-water farther down the stream.

---

[7] Watermaster, Snake River Dist. 36, Idaho Falls, Idaho.

In such instances, first construct a diagram similar to the author's Fig. 7 for a standard cross-section and degree of channel roughness, referring it, for convenience, to one of the gauges only. From time to time, as current-meter measurements are made, plot them on this diagram, and the amount in gauge height by which they fail to plot on the proper fall curve is the correction factor to apply to the observed gauge heights before using the diagram to determine daily discharges. On alluvial streams this correction factor may vary considerably from one measurement to another, due to continuing changes in cross-section. The changes thus indicated may be applied, as to time, gradually from one measurement to the next, or the change may be concentrated at the time of sudden changes in stage between measurements in the manner customarily used in the so-called "shifting-channel" method of determining discharges at stations of variable rating.

Benjamin E. Jones,[8] Assoc. M. Am. Soc. C. E. (by letter).—Back-water at river measurement stations has always been a source of complication to the hydraulic engineers of the U. S. Geological Survey, as it disturbs the relation of stage to discharge. An example of this effect was encountered at the station on the Tennessee River at Chattanooga, where the stage and slope are affected by back-water from Hales Bar Dam, by the operation of the power plant, by leakage under the dam, and by the operation of the flash-boards on the dam. To meet this situation M. R. Hall, W. E. Hall, and C. H. Pierce, Members, Am. Soc. C. E., at that time hydraulic engineers of the Geological Survey, developed a method of determining the discharge of rivers of variable slope.[9]

Their method is similar to that of Mr. Blanchard. Messrs. Hall and Pierce used two gauges to determine the slope or fall. They then selected a fall which they considered normal and for each current-meter measurement at the station they computed the flow for the so-called normal slope by the equation,

$$Q_n = \frac{Q_1}{\sqrt{\frac{F_1}{F_n}}} \qquad \ldots\ldots(9)$$

In this formula, Q_1 equals the actual discharge; Q_n, the "normal" discharge; F_1, the actual fall between gauges; and F_n, the "normal" fall. This is the same as Mr. Blanchard's Equation (4), but in slightly different form. A "normal" discharge curve is drawn through the points obtained in this way, and the daily discharge at any given stage is then found by the equation,

$$Q_1 = Q_n \sqrt{\frac{F_1}{F_n}} \qquad \ldots\ldots(10)$$

---

[8] Chf., Power Div., Conservation Branch, U. S. Geological Survey, Washington, D. C.

[9] *Water Supply Paper No. 345-E,* U. S. Geological Survey.

In applying the method the letter, z, was taken as representing $\frac{F_1}{F_n}$. A table was then prepared giving the values of z and $\sqrt{z}$ for each gauge height. The true discharge was obtained by multiplying the "normal" discharge by the $\sqrt{z}$ factor taken from the table. Mr. Blanchard obtains the discharge by a series of curves each of which shows the discharge for an assumed fall.

Both methods of procedure are based on the assumption that C in Chezy's formula is a constant for a given stage and section of channel regardless of the slope. The best information available on this point is that furnished by measurements by Mr. Blanchard on the Chicago Drainage Canal, which indicate that the slope has no effect on the value of C. These measurements, however, cover only one case, where the conditions were not as complicated as in a natural river channel, and they can not be taken as conclusive. Little fault can be found with the theory underlying either of the methods and they are being applied with good results at several stations maintained by the Geological Survey.

For several years Warren R. King, Assoc. M. Am. Soc. C. E., obtained the discharge at Chattanooga by the following method: A slope-velocity curve was determined by plotting mean velocities obtained from discharge measurements at Chattanooga against the total slope between Chattanooga and Hales Bar. A stage-area curve was determined by plotting areas obtained from discharge measurements at Chattanooga against corresponding gauge heights. To ascertan the daily discharge, the velocity was first obtained by applying the mean daily slope (Chattanooga to Hales Bar) to the slope-velocity curve. The area was then obtained by applying the mean daily gauge height for the gauge at Chattanooga to the stage-area curve. The product of the area and velocity thus obtained gave the daily discharge. This method gives satisfactory results except for low stages, when there is very little fall between the gauges. Theoretically, this method would seem to be applicable only where there is little change in stage.

A. W. Harrington, M. Am. Soc. C. E., supervises several gauging stations on canals where conditions similar to back-water are caused by growing vegetation. At these stations not only the slope, but the value of C changes, and he uses the Chezy formula directly in determining the daily discharge. The coefficient, C, is computed for each current-meter measurement and plotted against a time scale. A smooth curve, drawn as nearly as possible through the plotted points, shows the variations of C throughout the season and indicates the coefficients for intervening days. The other factors in the Chezy formula are obtained from gauge-height records and the cross-section of the canal. This method is said to give good results, except when the slope factor is too small to use satisfactorily.

For conditions of rapidly changing stage, C. E. McCashin, and E. D. Burchard, Assoc. Members, Am. Soc. C. E., have used a series of curves based on gauge height and discharge, with curves for various rates of rising and falling stage. These curves are based on actual measurements during periods of changing stage, without resort to any formula.

The writer devised a method of estimating the slope due to a rising or falling stage and then obtaining the discharge for normal conditions by the use of the Chezy formula. He assumed that a rise or fall in stage travels down stream at the same speed as the surface velocity of the water. This has been found to be true of streams that have an appreciable fall and velocity. In lakes or behind dams the change in stage probably travels as a wave at a high velocity, and the effect of any change of stage on the slope is negligible. The formula as developed is, as follows:

$$\frac{Q_1}{Q_2} = \frac{\sqrt{S_1}}{\sqrt{S_1 + \dfrac{\text{Rate of change of stage}}{\text{Surface velocity}}}} \quad \text{.............} (11)$$

in which, Q_1 and S_1 represent the discharge and slope at constant stage, and Q_2, the discharge at the given rate of change of stage. This method[10] has been used for many years with good results. Where large and rapid changes of stage are frequent it is better to install slope gauges and obtain the actual slope.

In using any method for computing stream flow in a section where back-water exists, it is necessary to study the local conditions that cause the back-water and to adjust the method to them. The method outlined by Mr. Blanchard is excellent and probably can be adapted to fit a variety of local conditions.

A. J. MATHESON,[11] ESQ. (by letter).—The writer has found this paper and the discharge diagrams presented therein, very interesting, particularly so because, since about 1916, he has been using a method of back-water computations which he developed, based on the same theory, but expressed by a different fundamental, or base-discharge curve, and extended upon somewhat different lines. Computations by either system, if based on the same precise data, should give exactly the same result.

In preparing his base-discharge curve for the example illustrated, Mr. Blanchard arranged the observations in groups (Table 2), in each of which the mean stage was approximately the same. He then plotted the mean elevation of each of these groups against the mean of the corresponding computed falls for a discharge of 8 000 cu. ft. per sec. The writer would suggest plotting the result of each individual observation, in obtaining the curve, because, by this process, any computed data which are obviously inconsistent can be eliminated and the general trend of the relations can be more closely analyzed. The conditions existing in the example he used for illustration are decidedly sensitive, since most of the recorded falls are well under 1 ft.

In the application of this method to any particular case, the field data required consist of a number of discharge measurements covering the range of flow, together with the corresponding records of the elevations of the water surface at the upper and lower ends of the reach. Since the accuracy of the final computations and curves is dependent upon the precision of these data, it would seem advisable to stress the following points:

---

[10] *Water Supply Paper No. 375*, U. S. Geological Survey.

[11] With Dominion Water Power and Hydrometric Bureau, Dept. of the Interior, Ottawa, Ont., Canada.

(1) There must not be any variation in the volume of water flowing through the channel from the upper to the lower gauge, due to streams flowing into it or channels leading out.

(2) The gauges must be tied in to a common datum so that the precise fall in the water surface between the two gauges may be obtained.

(3) The gauges, if possible, should be located so that during the time in which discharge measurements are being taken, there will be a fall of at least 2 ft. in the water surface between them. As the computed discharges are dependent on the square root of the fall, an error of, say, 0.10 ft. will cause a greater discrepancy with a total fall of 0.5 ft. than it would if the fall were 2 ft., or more.

(4) The gauges should be located so as to be as free as possible from the effect of local disturbances, such as eddies, wind, etc.

(5) The actual distance between the gauges is not important, as long as the flow is uniform throughout the channel.

(6) It is not essential that the cross-section of the channel should be the same throughout its length. It is essential, however, that there shall be no change in the channel cross-sections, such as erosion or silting of the sides or bottom, during or after the observations.

(7) Care should be taken to see that, during the time that measurements are being taken, the flow in the channel is not fluctuating and that the backwater conditions are not changing.

(8) This method of computation is not applicable to free falls, but its use is not confined to a straight-line, smooth water surface, between the recording gauges. The writer, using his own diagrams, computed the elevation at seven intermediate gauges along the rapids of the St. Lawrence River near Morrisburg, Ont., Canada, when levels had been taken after an ice jam had raised the water 10¾ ft. at the lowest gauge and 4 ft. at the upper gauge. His computed elevations at these seven gauges varied from an exact check, to a maximum difference of 0.14 ft. from the actual levels recorded by two independent parties of Government engineers. For the same flow under summer conditions the fall through these rapids is 10 ft. in a distance of about 3 miles.

L. STANDISH HALL,[12] ASSOC. M. AM. SOC. C. E. (by letter).—This paper offers a solution to a troublesome hydraulic problem frequently met in the measurement of stream discharge.

The influence of a water surface with variable slope on the discharge relation affects the results on streams more frequently than is ordinarily appreciated. When the change in slope is quite marked this condition is readily identified. However, in many instances, the effect of the variation in slope is so slight that it is confused with a shift of control. In cases where a variable surface slope is combined with a shifting control, the separation of the two effects is often quite difficult.

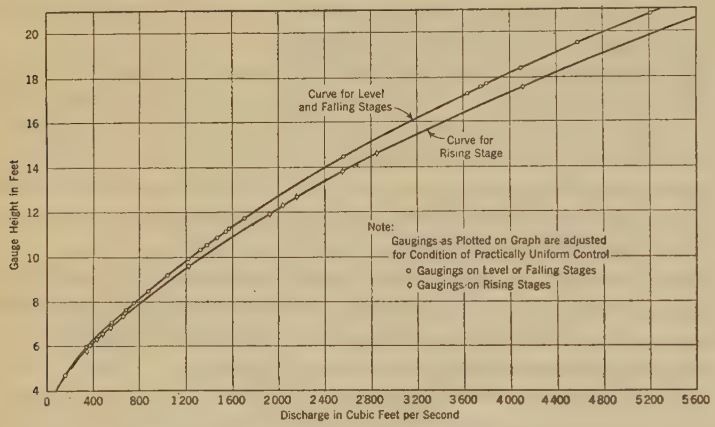
---

[12] Chf. Hydrographer, East Bay Municipal Utility Dist., Oakland, Calif.

A control is effected on a stream, when the water surface proceeding in the direction of flow changes from a flatter to a steeper slope. Some controls are so slight that they are "drowned out" when higher stages are reached, and the condition of variable surface slope is introduced.

Before classing a station as one affected by a variable surface slope, a careful check on the condition of the intake pipe to the recorder well should be made, since a partly plugged intake pipe can create the effect of larger discharges on rising stages than on falling stages.

In Fig. 10 is shown the discharge curve for a part of the measurements taken on the Mokelumne River, at Woodbridge, Calif., for the year 1927. The separation of the curves for rising and falling stages is easy to distinguish. The interpretation of measurements at this station is further complicated by shifts in the control. The points plotted on the graph have been adjusted to represent times when the condition of the control was particularly uniform.



Note: Gaugings as Plotted on Graph are adjusted for Condition of Practically Uniform Control

FIG. 10.—RATING CURVES, MOKELUMNE RIVER AT WOODBRIDGE, CALIF., FOR YEAR 1927, SHOWING EFFECT OF VARIABLE SURFACE SLOPE

The variation between the two curves does not exceed 10% of the flow, so that, in this case, reasonably accurate discharges could be determined by the use of one average curve to represent rising stages and a second for falling and level stages. Although it is true that a transition from one slope to another must exist, the results of the discharge measurements would appear to indicate that such transition periods are of brief duration.

RAY E. MACKENZIE,[13] ASSOC. M. AM. SOC. C. E. (by letter).—The author has afforded a good opportunity for discussion on the subject of back-water effect at a measuring station. While he has simplified the problem of determining the discharge at a station subject to back-water, further simplification is desirable. The form taken should be that which best suits the immediate purpose. If this is the reduction of gauge heights to daily discharge figures, there can be no better arrangement than the table. This must result from a graph, as all rating tables do, and will consume considerable time in preparation. However, it must be remembered that the task of reduction to discharge is the main one, and it is here that simplicity, speed, accuracy, and facility for checking are of paramount importance. The rating table is the common and accepted means of reduction, and, therefore, a simple form of it should be the more logical method of transfer.

---

[13] Associate Hydro-Elec. Engr., U. S. Engr. Office, St. Louis, Mo.

The use of separate tables, one for the "normal" discharge and the other giving values of $\sqrt{z}$ would produce the desired result from a single multiplication, but two interpolations might be necessary. A tabular representation of Fig. 7, with columns headed "Fall, in feet," and lines to read "Elevation below Chicago City Datum," would condense the data into a single table. With attention given to the probable accuracy of the data, the table could be made so that hasty interpolation could be accomplished to the percentage of accuracy required.

Numerous applications have been made of the principles involved in the paper. For some time the writer has used the principle in the reverse condition, that is, for back-water computation. The problem is the familiar one with back-water above a dam. The discharge to consider is known and the solution is for the back-water elevations at various points up stream.

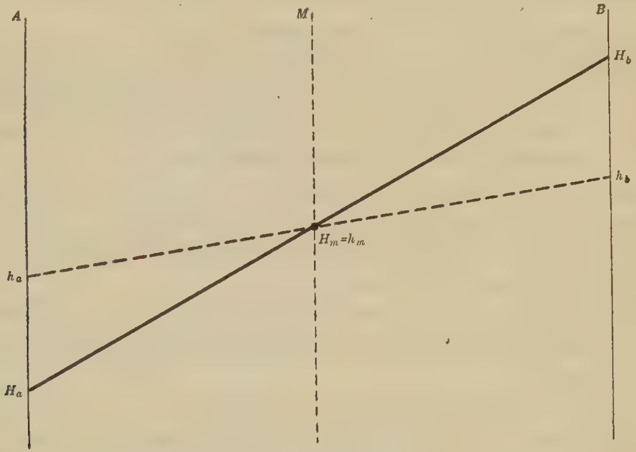


FIG. 11.

Natural flood elevations and discharges are determined from field surveys with attention paid to the elevation and discharge at the time of the survey and to the probable point of zero flow. Often a satisfactory rating curve can be made and extended from as few as three points on full logarithmic paper.

A study of sections that form major and minor controls for various stages of flow will materially help the drawing of the curves and their extension to the elevations of probable back-water. Separate rating curves are drawn for each section forming an end of a reach. While these should be made so as to show properly the stage of zero flow (or approximately), it is very helpful in studying the curves and their extensions to draw the rating curves on a common scale of elevation. On such a graph the intersection of curves will show a level slope between the sections represented.

In Fig. 11, let F from Equation (2) equal $H_b - H_a$; in Equation (3) let $F_x = h_b - h_a$, and $q = Q_x$. Then, if Equation (12),

$$Q = K\,(H_b - H_a)^{0.5} \ldots\ldots\ldots\ldots\ldots\ldots\ldots (12)$$

is used as the formula for natural flow, and Equation (13),

$$q = k\,(h_b - h_a)^{0.5} \ldots\ldots\ldots\ldots\ldots\ldots\ldots (13)$$

for back-water flow, and, furthermore, if h_m is made equal to H_m, then k equals K, and the author's Equation (5) becomes,

$$h_b - h_a = (H_b - H_a)\,\frac{q^2}{Q^2} \ldots\ldots\ldots\ldots\ldots\ldots (14)$$

In back-water computations, q is known and the point, h_a, is determined from the computed rise or back-water at the dam or obstruction. Then, if the assumption can be made that $h_m = H_m$, a working basis will be found to proceed with the back-water computation. The order follows:

(1) Assume a value of h_m that equals H_m.
(2) Enter the rating curve for Section M with H_m and read Q.
(3) With Q known, H_b can be read from the rating curve for Section B, and H_a can be read from the rating curve for Section A.
(4) In Equation (14) substitute values for q, Q, H_b, H_a, and h_a; then compute h_b (the new back-water point).

The method is, of course, a cut-and-try one, but it gives good approximate results when a poor assumption of $h_m = H_m$ is made. If refinement is required a possible second trial should be sufficient to produce a satisfactory computation of the back-water elevation.

Since the rating curve for Section M is the average of the B and A curves, its elevations will be midway between them, and the curve for M need not be drawn.

The writer has used the method and variations of it for several years. He finds that sometimes a computation of the roughness coefficients for a few of the natural and back-water elevations is helpful in confirming the computation. He believes that the method, where it can be used, enables a useful and practical solution of back-water computation.

MURRAY BLANCHARD,[14] M. AM. SOC. C. E. (by letter).—The writer is gratified and pleased with the discussions of his paper. They contain suggestions to simplify the procedure and indicate numerous uses that have been made of the principles and theories involved. The arguments relate to the different features or steps in the derivation of the discharge diagram and its uses, and will be treated separately.

The Base Curve.—Mr. Macphail proposes a substitute curve of K, referred to stage and discharge, to be used as a base from which, by Equation (2), are obtained the curves of the discharge diagram (Fig. 7). The base curve is derived from Equation (2) transposed to,

---

[14] Cons. Engr., Chicago, Ill.

$$K = \frac{Q}{F^{0.5}} \dots\dots\dots\dots\dots\dots\dots\dots\dots (15)$$

General Pillsbury proposes the same curve in different terms. His is a curve of 1-ft. fall (Fig. 9), obtained by making F unity in Equation (4), whence,

$$Q_x = \frac{Q}{F^{0.5}} \dots\dots\dots\dots\dots\dots\dots\dots\dots (16)$$

and $K = Q_x$.

Mr. Perry uses the same relation (Equation (2)), as the others and obtains a diagram of K curves referred to discharge and fall. These are, in effect, a series of base curves, but the procedure is lengthened by the necessity of determining the valves of (A), (C), and (R), in order to obtain a discharge corresponding to a given stage and slope.

Mr. Matheson does not state, but in correspondence with the writer he has revealed, that his method, developed about 1915, makes use of the 1-ft. fall curve (Fig. 9), and he calls it the "unit-fall" method. His suggestion to plot the resulting unit-fall discharges derived from each observation, in order to note any inconsistencies, is not considered by the writer as a necessary step because at any elevation all the observations, if they gave true discharges, would reduce to the same quantity. Comparison of these figures will enable one to detect any inconsistencies and will permit the elimination of abnormal observations. The arithmetic mean will give the best determination of a point on the base curve. The points plotted to determine the curve of Fig. 9, as well as the points for the base curve, Fig. 6, are groups or arithmetic means.

The K and the unit-fall base curves are the same as the writer's 1.0-ft. curve of fall in Fig. 7 and, as a slightly shorter operation, he would suggest the substitution of Fig. 9 for Fig. 7. The resulting discharge diagram will not be effected.

The Chezy Formula.—The references of Mr. Perry to the Kutter formula do not appear to be pertinent to the method adopted in the derivation of the discharge diagram for the reasons stated in the paper, that, "for a single stage under consideration the factors, (A), (C), (R), and (L), are constant" and are eliminated in the derivation of Equation (4) or Equation (5) from Equations (2) and (3). If Mr. Perry chooses to use his diagram (Fig. 8), the writer would suggest, for the determination of C, the Manning formula or the Kutter formula with the s terms omitted, which gives practically the same results, as proposed[15] by H. W. King, M. Am. Soc. C. E.

In the Chezy formula, $V = C\sqrt{RS}$, the factors, V, C, R, and S, are the means for the reach under consideration. Because the discharge is often measured at an end station, the velocity or hydraulic radius at this end station is frequently used as if it were the mean for the reach. Such an approximation will ordinarily give satisfactory results, as in Mr. Jones' method of correcting discharge for changing stage.

---

[15] Hydraulics," by King and Wisler, 1922 Edition, p. 190, and "Handbook of Hydraulics," by Horace W. King, Second Edition, 1929, p. 261.

Normal Discharge.—This is a term of general usage that serves a useful purpose in the investigation of certain stream flows; but it is not for the general application that is sometimes given to it. It has been explained[16] as the discharge at a stage which would be caused by a slope that is the average of all the slopes that obtained for the period of record. Such a slope may never occur at the stage under consideration, especially if this is a flood stage. Such discharges should be labeled "normal," and the period of record and average slope used should be noted. Mr. Jones states, in reference to the Hall-Pierce method, which is based on Equations (9) and (10), how the true discharge was obtained by multiplying the 'normal' discharge by the $\sqrt{z}$ factor taken from the table." This "true" discharge is the one corresponding to the stage and slope of an observation, and the "normal" discharge curve from which it is obtained, is, in effect, a "base" discharge curve. There may be similarly obtained for the same stage, a large range of "true" discharges, depending on the various slopes that occur. Thus, the Hall-Pierce method is similar to that of the writer and is also applicable on streams to which the rating curve applies as well as where a range of slopes occurs at the various stages. The situation on the Tennessee River, at Chattanooga, which the "normal" stage method was designed to meet, is one in which the discharge diagram can be used to obviate the necessity of approximations.

Reference to Other Than Mean Stage.—The method of Mr. King, to which Mr. Jones refers, and that of Mr. Crandall, wherein discharges are referred to the stage at one station instead of the mean elevation of the reach, are approximate methods, but with a considerable field of adaptability. The writer has similarly used discharge diagrams, referred to a station at the end of a reach, to advantage in studying flood flows of the Lower Illinois River. The approximation comes in the assumption that the stage at other than the mean station varies as the mean stage. This assumption does not hold in a case in which there is artificial regulation above and below a reach, and hence it does not always follow that, for a single (other than mean station) stage under consideration, the factors (means for the reach), (A), (C), (R), and (L), are constant.

Application to Back-Water Computations.— Mr. Mackenzie has made application of the stage-slope-discharge relation to the determination of the back-water curve. He applies it to the condition of a stream in which there is only one discharge corresponding to a stage. A calculation can be made that would be applicable to all open channels, by a "cut-and-try" method with the discharge diagram. Thus, referring to the Chicago Sanitary District Canal, for which there is no established rating curve—and upon which the experiments were made that were used in this paper to demonstrate the derivation of the discharge diagram—the following is an example, using Mr. Mackenzie's notation and Figs. 11 and 7.

---

[16] *Water Supply Paper No. 345,* U. S. Geological Survey.

The problem is as follows: While flowing 8 000 cu. ft. per sec. in the reach from Willow Springs (B) to Lemont (A), the water surface is raised to — 4.85 at (A). What will be the resulting water surface elevation at (B)? The solution is:

	First trial	Second trial
Assume $F_x =$	1.1	1.0
From Fig. 7, or Table 3, $h_m =$	—5.04	—4.35
$\frac{F_x}{2} =$	0.55	0.50
$h_m - \frac{F_x}{2} = h_b =$	—5.59 (too low)	—4.85 (O. K.)

From the second trial, which checks for 8 000 cu. ft. per sec., the assumed fall, added to h_a, gives — 3.85, the required elevation.

2.4......	....	....	....	....	....	....	....	11 300

Rating Table.—As stated by Mr. Mackenzie a rating table may be desirable. In Table 3, note that, in each stage column, the discharges, 8 000 cu. ft. per sec., are the points where the base curve (Fig. 6) intersects the "fall" lines at 0.5 ft. to 1.2 ft. The stages thus obtained, — 0.90 to — 5.73, were used as convenient elevations along which to transpose the discharge-stage-slope relation. If Fig. 9 is used instead of Fig. 6 for a base curve it would be more convenient to use the even foot stages, — 1.0 to — 6.0.

Discharge Diagram.—From the variety of practical uses that can be made of the discharge diagram it would appear, generally, to be worth the effort to develop. General Pillsbury has suggested that the base curve (Fig. 9), is sufficient and that, instead of developing the discharge diagram, he would calculate from the curve, for given data, the discharges as required. The other extreme is taken by Mr. Mackenzie who would construct the discharge diagram and from it make a rating table. The writer concurs with him that "the form taken should be that which best suits the immediate purpose." From the Chicago Sanitary District Canal experiments the writer produced,[17] several years ago, a diagram of discharge referred to the elevations of the end stations. Mr. Matheson has developed a stage-slope-discharge relation of this form by the use of unit-fall base curves and has made extensive application. His suggestions as to precautions to be taken in making discharge measurements for this purpose are pertinent.

LEGAL PROBLEMS INVOLVED IN ESTABLISHING SET-BACK LINES[1]

By Clifton Williams,[2] Esq.

With Discussion by Messrs. J. M. Albers, J. E. Willoughby, Horace H. Sears, George H. Herrold, Clifford C. Muhs, H. B. Cooley, Walter C. Sadler, H. J. McFarlan, Donald M. Baker, and E. G. Walker.

Synopsis

When fire, flood, disease, or other calamities threaten the people of a community, National, State, and personal property may be sacrificed without compensation. This paper calls attention to a new idea, based on the age-old function of sovereignty; namely, that if narrow streets in a community become so dangerous as to require widening for the preservation of public health and safety, the acquirement of property for such widening is properly a function of sovereignty.

If the Courts could be convinced by engineers that street-widening problems are indeed functions of sovereignty, the tremendous financial problems encountered at present would be solved. Set-back lines could be established on narrow streets by giving due notice that in ten, twenty, or thirty years from that date the property thus segregated would revert to public ownership. In the meantime, the private owner would have time to make the necessary adjustments to meet the requirements of such a law.

Introduction

The term, "set-back lines", as used in this paper, refers to those established for the purpose of future widening of streets for traffic and not to the so-called set-back lines employed in zoning which were established to mark bounds beyond which buildings shall not be constructed.

Later, the so-called zoning lines or building lines are mentioned in connection with some Supreme Court decisions which established the validity of such lines, without compensation to the abutting owner. The set-back line for street widening is only one step farther and is as clearly within the field of governmental sovereignty as the other form.

---

[1] Presented at the meeting of the City Planning Division, Milwaukee, Wis., July 11, 1929.

[2] Special Asst. City Attorney, Milwaukee, Wis.

The main purpose of this paper is to help engineers realize that the Courts are not trifling with this subject and that lawyers are not trifling with the Courts when they maintain that the street-widening problems of America are just as much problems of sovereignty as fire-fighting, quarantine to prevent the spread of disease, the abatement of nuisances, the struggle to prevent the spread of crime, etc.

Police Power and Set-Back Lines

This effort is prompted by repeated remarks made to the writer by city planning engineers and others who are devoting the best years of their lives to this work, to the effect that they are "in a fog" in attempting to understand the legal somersaults that are apparently going on throughout the United States. Even law students do not understand the term, "police power", and they do not understand clearly how there can be a phase of sovereignty involved in this problem, which is older than any constitutional provision on the subject.

If this legal problem is solved along historical lines and if the Courts are finally convinced that the tremendous street-widening problems of this country are problems of sovereignty, and if the decisions are quite uniformly announced to that effect, then the great financial problem that is involved is also solved.

In other words, if the Courts would uniformly hold that the great American problem of widening streets to take care of present and future traffic needs is a problem of sovereignty, then as a matter of sovereignty the streets and highways can be widened the same as buildings can be destroyed to prevent the spread of fire or the same as a high-salaried man can be quarantined to prevent the spread of disease. All these things are done under a recognized governmental power which is older than any Constitution. Under such circumstances the property that it is necessary to acquire, has not been taken for a public use under any clause of any State or Federal Constitution and it is not necessary to pay compensation to the abutting owner.

The mere statement of the proposition creates resistance and the writer proposes not only to show how historically sound it is; but to show how close some of the Courts are to a correct solution of the problem.

No space will be devoted to a statement of the necessity of widening streets and highways throughout this broad land. Engineers are more familiar with that phase of the question than the writer, who will just take it for granted. The enormous financial problem involved also requires no further discussion other than a re-statement of the fact that the correct solution of the legal problem at the same time solves the financial problem. Of course, the financial and legal problem is twofold because now it is not only necessary to re-build the old "horse-and-buggy" streets into automobile highways, but it is also necessary to plan for future requirements, along the streets which are being laid out, with the tremendous growth of self-propelled vehicles in mind.

The Engineer in Relation to Legislation Concerning Set-Back Lines

Without any reflection on engineers the writer knows from personal talks with them that quite generally they are not familiar with the Constitution of the State in which they practice. Ordinarily, the engineer realizes somewhat vaguely that there is a clause in his State Constitution as well as in the Federal Constitution to the effect that private property shall not be taken for a public use without compensation. The engineer is quite thoroughly convinced that the widening of a street and the establishment of a set-back line involves the taking of property from an abutting owner for a public use and, for that reason, compensation is necessary. Then he gasps at the billions and millions of dollars that are required to do what ought to be done to the present "horse-and-buggy" streets in order to convert them into automobile highways.

Engineers can do a great service by compiling and broadcasting throughout the land an estimate of the billions of dollars which it would take to put the highways of the United States in a safe condition for automobile traffic. A few years ago the writer drew the first ordinance for regulating the heights of buildings in Milwaukee, Wis. Twenty years previously (1910) the regulation of building heights in this country was practically unknown. Legislators were still adhering to the old principle that a man had the right to do with his own property what he pleased as long as he did not reach over on to his neighbor's property and commit some active trespass. The Courts had already recognized that he might reach over actively either by creating offensive odors or a nerve-racking noise; but up to the time of the Milwaukee ordinance no one had admitted that the regulation of building heights was a function of sovereignty. At about that time American engineers offered the statement that there were enough people on Lower Manhattan Island at ten o'clock in the morning to fill the streets to the top of the fourth floor windows if, for any reason, the people should rush into the street at the same moment. That statement startled the country and the Courts began to realize that the regulation of building heights was in fact a function of sovereignty. Since then they have held that the municipal units have the right to say that building heights shall only reach certain limits for the simple purpose of preventing more people from getting into a district than can be accommodated in the streets.

What the writer wishes to emphasize is that if the engineering societies of this country will inform the Courts of the billions of dollars that are required at the present time to put the "horse-and-buggy" streets in a safe condition for automobile traffic and, at the same time, tell them of the tremendous loss of life and damage to property that is constantly taking place, due to the fact that such streets are not safe for automobile traffic, these organizations will thereby do much to cause the Courts to realize that the solution of this great traffic problem is a function of sovereignty.

There is nothing new or novel in this suggestion. The writer does not intend to do any violence to the clause in any Constitution which, in round phrases, states that private property shall not be taken for a public use without compensation. All he suggests is that the Courts, through the engineers, should be made to realize that the great traffic problem of this country to-day is as much a problem of sovereignty as fire-fighting, quarantine to prevent the spread of disease, the peremptory destruction of nuisances, entry upon private land to construct levees to prevent great rivers from destroying property, and the various other phases of recognized sovereignty.

The writer knows from personal experience that engineers and city planners have had more to do with the establishment of the legality of the building heights regulations and zoning laws than the legal profession—in that engineers and city planners furnished the facts, figures, etc., and, in some instances, even submitted non-technical briefs to the Courts. Furthermore, engineers can do more than lawyers in convincing the Courts that the present tremendous traffic problem (which is at the bottom of the requirement of set-back lines to street widening) is a phase of sovereignty.

The lawyer will simply declare that it is a struggle between the police power and the Constitutions of the various States. The term, "police power", is a very unfortunate one. It suggests bluecoats, brass buttons, and billy-sticks, or something of that kind, when, in fact, it means the power of government or sovereignty, or the power of a people to preserve itself.

Private Property for Public Use Without Compensation

Mere words are often misleading unless the reader is able to go back of them, into history, and know the fundamental principles. Consider the Federal Constitution and the Constitutions of all the States. They contain a composite provision that private property shall not be taken for public use without just compensation. The word, "property", offers no difficulty. Some difficulty may be encountered with the word, "taken", but it is necessary to trace the meanings even farther back. Every one knows that even before the establishment of any American colony, Governments were taking property as a phase of sovereignty without compensation, and they are still doing it. For illustration may be cited: Quarantine; the abatement of public nuisances; the destruction of contaminated food; the destruction of valuable buildings to prevent the spread of fire; the confiscation of gambling devices; and the peremptory right to enter upon private land and repair levees, which is quite common throughout the Southern States.

Many other illustrations of sovereignty might be cited, most of which are older in principle than any Constitution in this country. These powers were extended to the very existence of sovereignty in its simplest form. They were all recognized before America was discovered as being phases of the power of government. When the Fifth Amendment to the Federal Constitution was written, which stated plainly that private property shall not be taken for a public use without compensation, no one had in mind the prevention or stopping of the further exercise of this recognized phase of sovereignty. The Constitution of the State of Wisconsin was written in 1848. Section 13 of Article 1 reads as follows: "The property of no person shall be taken for public use without just compensation therefor." Every one will admit that in those words there was no intention to abolish quarantine; there was no intention to prevent the destruction of buildings to stop the spread of fire; and there was no intention to abolish the power of abating nuisances. The Wisconsin Courts have recently ruled that the sovereignty of the State may say to a man that he may not put a certain kind of a building in a residence district (Carter *vs.* Harper, 182 Wis. 148); that he cannot construct his building beyond a certain height in a certain district; and that he cannot build within 15 ft. of the street on either side of a corner lot (Hayes *vs.* Hoffman, 192 Wis. 63).

If a person can be quarantined thus causing him to lose his salary without compensation, or if a Government can destroy his property to prevent the spread of fire, or if his land can be seized without compensation for the purpose of constructing a levee to prevent the spread of a river, then it should be possible to convince the Courts that the United States is confronted with a very dangerous traffic problem, the solution of which is necessary to existence. After that it is not a long step for the Courts to state that this traffic problem can be solved as a phase of sovereignty, and that the acquisition of the necessary property is not a prohibited taking within the constitutional provisions, any more than the other confiscations.

The Courts have already held, and are now uniformly holding that, as a phase of so-called police power or as an element of sovereignty, a State may prevent a property owner from building above a certain line or beyond a certain distance from the street line. It is not asking them to go much farther to require that they recognize that the present traffic problems and the necessity for street widening are indeed phases of sovereignty, and that the execution thereof can be carried out without compensation, the same as quarantine or the destruction of property for fire-fighting purposes.

Largely because engineers expect the law to be an exact science, they look upon the growth of such problems in the Courts with suspicion. They find certain words in a Constitution and expect to go out and erect a series of legal decisions with those words in the same manner as they use a plumb-bob to erect a perpendicular. The writer would urge that engineers be patient with the Courts and not lose their respect for them even if they do find them about-facing in a proposition of this kind. It is only natural that twenty-five years ago judges did not state that the automobile traffic was a problem of such seriousness that it was a phase of sovereignty, because then it was not such a problem. Is it now not a fact that the problem has become so nation-wide, that the loss of life and destruction of property are so tremendous, and that the present effort to use the old-style streets for self-propelled vehicles is creating so many difficulties and hazards that, in fact, the problem has become one of sovereignty? In widening streets and providing for the solution of the problem, the power of government must support the undertaking as, in the past, it has supported the effort to combat disease and the spread of fire.

Citation of Legal Decisions in Wisconsin

In the case of Hayes *vs.* Hoffman (192 Wis. 63), decided in 1927, the validity of the set-back line was established under a zoning ordinance. There is only a short step from that zoning set-back line to one that would result in the widening of those very streets for traffic purposes. The defendant owned a vacant lot on the northwest corner of a street intersection and the plaintiff was a neighbor across the street on the southwest corner. At that time, Milwaukee had a zoning ordinance which had not yet been interpreted by the Courts; it required a 15-ft. set-back line in that residence district. City officials had construed the ordinance to mean that the 15-ft. set-back line was applicable only to the front of the property and not to the side; in other words, that it would be applicable in that case on the street passing between the two properties. The defendant began building operations under that interpretation of the law. The plaintiff lived across the street and at the end of 31st Street so that if the defendant built within the 15-ft. line along the side street he would obstruct the view of the plaintiff. The latter enjoined the building operations on the ground that, by building to the 15-ft. line along the side street, the defendant obstructed his view, and the Supreme Court held that the 15-ft. set-back line applied to both sides. This left the defendant a piece of ground that was too small for building anything of value, but the City of Milwaukee paid him nothing, because it was established in Wisconsin that the zoning ordinance is an element of sovereignty.

In other words, it was enacted under the so-called misnomer, "police power". If, in this case, the defendant was unable to build on this 15-ft. strip on either side, has not his property been taken? And if that restriction is placed there for air, light, and sanitation, or for any other reason which can be written into a zoning ordinance, then was not his property taken for a public purpose? Nevertheless, there was no compensation, because the so-called "taking" was under a phase of sovereignty, which is older than any Constitution of this land. The defendant in this case was merely in the same position in which he would have been if buildings on these 15-ft. strips had been dynamited to prevent the spread of fire. He had no more claim against the public for compensation than if he had been quarantined away from a $25 000 job for two months to prevent the spread of smallpox.

This case can be used to define a line of demarcation between "the taking for a public use" as mentioned in the various Constitutions which requires compensation, and "the taking" in the case of Hayes *vs.* Hoffman which was undeniably a confiscation, but which comes under the head of sovereignty and does not require compensation. It is admitted that the owner cannot put any buildings on either one of the 15-ft. strips. He can run a lawn mower over both of them. He might have flower beds in them, but he cannot even build a dog house on either one of them. If the City permits automobiles to run over either one of these 15-ft. strips, the City apparently would have to pay the owner if it was done under any municipal recognition, although if automobiles gradually began driving over both the strips and kept it up for twenty years, the highway will be established without compensation. If the City should go in and run a lawn mower over these 15-ft. strips, or put in flower beds, there might be a claim that the City had made a park out of them and for that reason would have to pay compensation. The question is that narrow. The City in this very case prevents the owner from building over these 15-ft. strips so that air currents can pass up and down, so rays of sunlight may pass in, and so that the view of the street is improved; and this is all done without compensation. It is a short step to the claim that the City may permit automobiles to pass over the 15-ft. strips the same as light rays or air currents. The automobile traffic in either of the streets may be so tremendous that the City, in the exercise of its sovereignty, may class the problem as one that is just as dangerous to the people as any of the others.

Several years ago the Wisconsin Legislature was bold enough to state in one of these laws[3] that a set-back line as a notice of future street widening could be established without any compensation to the abutting owner.

The set-back line may be established without compensation; its establishment is not considered equivalent to the taking of property, although it does provide that the owner who builds over the line does so at his peril and cannot recover any damages for the building beyond the line. The validity of this statute has not been litigated in the Courts although it has been on the statute books for several years. The establishment of the set-back line has many elements of fairness, and it is not as harsh as quarantine, the destruction of buildings to prevent the spread of fire, or the destruction of farms to prevent the spread of a river. Another law recognizes the necessity of paying compensation to the abutting owner because the other law was drafted a great many years ago as a part of the charter of the City of Milwaukee, and in that age when the seriousness of the automobile traffic problem had not yet been realized.

The history of the world shows that sovereignty knows no limits. When put to the ultimate test it recognizes no property rights. The self-preservation of a people is a law unto itself. A written Constitution is an agreement between the then existing units of people who make it a sovereignty concerning the exercise of the phases of government mentioned therein, and there is not in existence a single Constitution which contains an abdication of all phases of sovereignty not mentioned therein.

A set-back line which serves to notify a property owner that within a reasonable time in the future it is apparent to the authorities that the governmental sovereignty will be called upon to expand a street for the solution of this great threatening problem, is much fairer to the property owner than the sudden destruction of his building to prevent the spread of fire or the peremptory and sudden quarantine of his body to prevent the spread of disease. The cry that generally goes up in the United States is that this is the richest country in the world and that the Government should pay and pay well for these strips of land necessary to convert the out-of-date streets into automobile traffic highways. This country may be the richest nation in the world; it may have the richest group of States in the world; but this problem is not a National one, although it is nation-wide, and it is not a State problem, although it exists in every State in the Union. It is a problem that must be financed ordinarily by the local municipal units, such as towns, cities, and villages, and it is a well-known fact that such municipal units are habitually financially embarrassed.

The writer has had some experiences with street widening that have changed his views considerably concerning the harshness that might be apparent at the first mention of the necessity of taking over this problem as a phase of sovereignty. In Milwaukee there have been many instances in which the remnants of property left over after street widening, were worth several times the original value of the entire lot before the widennig. Admittedly, there will be cases of hardship when the Courts are brought to realize that the necessity of street widening is a case of sovereignty (which means it will be done without compensation for the land taken); but there are hardships in every phase of the contact between the private citizen and the administration of public duties. In his twenty years of experience in municipal law the writer has been forced to recognize that even taxes are unequal; that the jury duty burden does not fall equally upon the public; and that the support of the public schools cannot be made equal. In fact, not one single burden in the public field can be said to fall equally upon the people. The statement that there may be hardships in the proposed solution of the problem does not condemn that solution. For each case of apparent injustice and hardship where there may be a set-back line in a necessary widening of the street without compensation to the abutting owner, there will be dozens of cases in which the widening of the street will create enormous additional property values. The advantage of the set-back line is that it can be so slowly and gradually established as a street line as to remove most of the injustice. It might even be provided in such a law that, if there must be a "taking" within five years of the establishment of the set-back line, there will be compensation; but that there should be no compensation after a 5-year notice of the establishment of the line. On some streets the advance notice might even be extended to ten years.

---

[3] The Wisconsin statute which claims that the set-back line can be established without any compensation to the abutting owner is Sub-Divisions (10) and (11) of Section 62.23, of the General Statutes.

Cases of the Exercise of Governmental Sovereignty

Suppose the City of Milwaukee should serve notice on an owner that five years from date his house would be blown up to prevent the spread of a dangerous fire which it is known would happen. That would give the owner plenty of time to move and re-adjust himself. And, again, suppose the City of Milwaukee should say to a man that he would be quarantined in five years for three weeks to prevent the spread of a smallpox epidemic which the municipal authorities know is going to occur. The comparison does not need to be followed further. If it is recognized that the correct solution of this great traffic problem is a phase of sovereignty, then this set-back law provides for instrumentalities for removing the hardships which are incident to the very cases in which the Government does exercise its sovereignty without any compensation whatever.

As the United States continues to grow and its problems become more complex, a great many of the old ideas which have been instilled into the minds of its people will have to be discarded. People seem to like to say that "a man's house is his castle". They seem to enjoy saying that this is a country of liberty and a man has absolute ownership of his property. What is ownership? Nothing is more mythical than a title. Title is nothing but a gift of sovereignty. If title is claimed to a piece of real estate in America to-day, what is the nature of that claim? It is merely an evidence that some one took the land away from the Indians as a matter of military strength, or by some other method of that kind, and that as a matter of sovereignty there is, at the beginning of the chain of title, a patent from the Government. That title is no stronger than the sovereignty under which citizens are living.

The very existence of the title depends on sovereignty. In fact, the title is simply an instrument of sovereignty, because the Government with its Courts is what makes the title to land good, so that, after all, there is not much hardship in permitting sovereignty to deal with that title or to restrict it so as to comply with the requirements that spring up in the self-preservation of a great people. For instance, consider the statement that people like to "roll under their tongues" to the effect that "a man's house is his castle". When two castles are built close together things begin to happen. For instance, one castle owner cannot dig down on the property line so as to disturb and cause the soil of the neighboring castle owner to fall in. As a result the easement of lateral support has grown up. One castle owner cannot run a tannery on his property so as to offend the nose of his neighbor. Things gradually developed so that he was not allowed to create other nuisances, such as disturbing noise. When a castle owner lived all alone he could throw his garbage out on the surface of the ground, but when other castles commenced to be built in the neighborhood he found that his so-called liberties were being restricted. As the castles continued to spring up, their owners found that they could not build so close to the property line as to shut out light and air; and in the great cities buildings cannot be constructed so as to attract more people to the district than can be accommodated safely. It is not going very far to state that, since it is recognized that a castle owner must give up many of his so-called rights, such as in the case of zoning and building height restrictions, he will likewise have to give up land so that streets may be expanded to solve one of the greatest problems that has ever confronted any country.

Conclusion

American Courts will soon hold uniformly that the solution to the traffic problem is a phase of sovereignty and that private rights shall give way, as they must, to fire-fighting, abatement of nuisances, prevention of crime, the operation of levees, and to those other forms of sovereignty that are happening every day. When that time comes the public will accept it the same as they accepted zoning, building-heights regulations, billboard ordinances, health regulations, ordinances confiscating contaminated food, laws confiscating gambling devices, laws permitting the restraining of floods, and other recognized phases which are accepted without question and without any compensation whatever to the people who are being called upon to submit to the exercise of the sovereignty.

DISCUSSION

J. M. ALBERS,[4] ESQ.—It appears from a study of the Court decisions affecting zoning, and particularly from some of its special phases, that the legality of regulations creating building set-back lines is established. This statement can be accepted without undertaking a lengthy discussion of it, because supporting decisions may be found all the way from the United States Supreme Court down to the Lower Courts.

In the Chicago, Ill., Region, city engineers and planners are especially interested in the legality of set-back line legislation from the standpoint of its possible application to street widening. They are well aware of the contention that such an application of this principle encroaches upon the realm of eminent domain in that it may constitute a taking of private property for public use without compensation. There seem to be plenty of advocates on both sides of the case of police power *versus* eminent domain when street widening is being discussed. Is not an owner deprived of the use of his property by a zoning set-back line just as much as he is by a set-back line for future widening? Is not the establishment of a building set-back line on a future wide street just as much in the interest of public health, safety, convenience, and welfare as any other set-back line? The preservation of these things is the objective of police power. The actual taking of land can be left until the physical work of widening is to be undertaken. In the last few years the application of the police power has found a much greater field of usefulness in zoning legislation, and the large number of zoned communities in the United States bear witness to the success and propriety of this form of regulation. Practically all the existing zoning ordinances contain set-back provisions, and these are established in the interest of public health, convenience, and welfare.

Streets, adequate as to location, width, point of origin, and destination are of tremendous importance to proper civic development. Public safety and welfare are perhaps, to-day, more dependent upon the proper provision of streets than upon any other single function of government. The rapid growth of urban communities is continually demanding streets wider than those originally laid out. The larger the community the more difficult it is to secure the wider rights of way. The cost of condemnation is in many cases a greater burden than the community is able to bear and, therefore, these highly necessary improvements are delayed and sometimes abandoned to the detriment of the entire community.

At the time when he published the plan for the City of Chicago, the late Daniel H. Burnham recognized the advantage of set-back lines for future street widening and recommended that the city acquire sufficient front-yard space to prevent future encroachment. If the necessity for wider streets is admitted and, at the same time, if the fact that the cost of condemnation will prevent much necessary improvement also is admitted, then city planners must seek further for a more economic method of accomplishing this work. The establishment of set-back lines now, under the police power, is the only practical method by which the widening of many traffic arteries can be secured in the future when greater width will assuredly be required. It is painless, economical, and has the decided advantage of making necessary a comprehensive plan for future street improvements and civic development.

[4] Sub-Div. and Zoning Engr., Chicago Regional Planning Assoc., Chicago, Ill.

The speaker believes that sufficient foundation has been laid to warrant some procedure along this line. The United States Supreme Court has ruled (Gorieb *vs.* Fox) that,

> "It is hard to see any controlling difference between regulations which require the lot owner to leave open spaces at the sides and rear of his house and a regulation which requires him to set his building back a reasonable distance from the street".

The Cleveland, Ohio, set-back ordinance has been sustained as a proper exercise of the police power, as was that of the Town of Windsor, Conn. In the last-mentioned case the Court decided that such legislation was not in violation of constitutional rights. The Courts of Wisconsin, California, Ohio, and several other States have all sustained set-back regulations. In the case of Kaufman *vs.* City of Akron, Ohio, the Court declared that the burden is upon the plaintiff; it is for him to show that set-back lines bear no substantial relation to public health, convenience, and welfare, before they can be declared invalid. In another Ohio case (Pritz *vs.* Messer) the Court ruled that the validity of the set-back law must be viewed in the light of probable future development. The speaker does not believe that any of the outstanding set-back decisions bear specifically on the use of set-back lines for street widening, but an array of opinion is being built up which, it is hoped, will finally sustain it. The construction of costly buildings in the bed of new streets must be prevented if there is to be any hope of progress toward adequate street systems. It appears that the regulation of the use of property to protect a major street plan is acceptable as to purpose, but there is a difference of opinion as to whether or not this should be accomplished through the police power or the right of eminent domain.

An examination of the Court decisions to date indicates that set-back laws are rapidly being sustained by the high Courts of the land as a proper exercise of the police power, and that resort does not have to be made to the power of eminent domain with its attendant prohibitive expense. If such legislation is worked out by the governing body on the basis of a well-defined policy, after a careful study of the entire area affected, and after due notice and hearing so as to avoid all charges of discrimination, arbitrariness, and unreasonableness, the Courts will not interfere with such legislation. Such enactments will speedily justify their own existence, and there is a growing sentiment in favor of them in the Courts as well as in public opinion. When such legislation is predicated upon public health, safety, convenience, and welfare, it is brought within the scope of a proper exercise of police power.

In the Chicago Region many communities are now protecting future street widenings by the present establishment of set-back lines for this purpose.

Some of these communities have passed ordinances creating such lines on specific streets, others are obtaining wider streets through agreement between the property owners and the city and village government. Still others have included the major street system with its required set-backs as a part of the zone ordinance. This latter seems to be the best method in that the city then has the opportunity to use the machinery set up in the Board of Zoning Appeals and this body is in a position to adjust those difficulties which are bound to arise in so comprehensive a piece of legislation.

J. E. WILLOUGHBY,[5] M. AM. SOC. C. E. (by letter).—One purpose of the written Federal Constitution is to limit the powers to be exercised over the people by Federal authority. That particular sovereignty advocated by the author is denied by the Federal Constitution, but (in the original draft) not to the extent which the debate in the various States (particularly Virginia) on its adoption developed was necessary for the protection of the people. Hence, ten amendments were introduced immediately after the Constitution had become effective and, in due course, they were adopted. Of these, the Fifth Amendment had particular reference to protection of private property against seizure for public purposes. This protection was further strengthened by the later adoption of the Fourteenth Amendment.

What the author is suggesting is a change in the Federal Constitution to be procured through such propaganda as will induce the Courts to issue decisions to the effect that private property, if taken under the guise of the police power, is not a taking such as is prohibited by the Fifth and Fourteenth Amendments. It may be assumed that the author is of the opinion that his purpose cannot be attained by repeal of the Fifth and Fourteenth Amendments although such a repeal probably would authorize public authority to take private property for public uses without compensation and without due process of law. The writer is not in sympathy with the suggestion. The exercise of the police power is properly used to further the comfort and safety of the people. That comfort and safety can be obtained without confiscation of private property.

The arguments advanced by the author as warranting a Court decision for the extension of the police power to include the taking of private property without compensation are not sound in that proper distinction is not made as between the principle which permits the lawful limitation of the height of a building and denies as unlawful the taking of an area of land occupied by the building. Every land owner of the fee of a part of the surface of the earth has the right to use it for lawful purposes, provided that such use does not take away in any particular the property rights of an adjoining owner. Among such property rights are sunlight and air. Whenever the height of a building destroys the right of another to full enjoyment of sunlight and air beyond the area covered by the building, then the height of that building can be fixed by law so as to remove the invasion of such a full enjoyment. The regulation of height of a building is not the taking of the property of the owner thereof, but is a prevention of the owner of the building from taking the property of another; which "another" may be the user of the public streets. The quarantine of a man with a contagious disease is not the taking of that man's property in form of wages, but is the prevention of that man from taking away the right of his neighbor to have freedom from infection.

---

[5] Chf. Engr., A. C. L. R. R., Wilmington, N. C.

The municipal authorities under the police power can properly decree a set-back line for building construction, and can forbid the use of the area between the set-back line and the edge of the street under the lawful principle of preventation of the lot owner from using his property to the detriment of others. So long as the municipality refrains from using as municipal property any part of the area between the street line and the set-back line, no property is taken; the rights of the adjoining others are protected, and nothing more. The actual conversion of such area to street purposes is the taking of private property for public uses which the Federal Constitution now forbids. The rights which develop from long-continued use are conditioned on another principle of law—open and notorious possession and use presume title in the holder and the user. Such is not a taking under the police power.

The fact that property needed for street widening is valuable and may cost the public much money, can never be a warrant for seizure without compensation. Possibly such was the thought and practice of Attila.

HORACE H. SEARS,[6] M. AM. SOC. C. E. (by letter).—The inclusion of "set-back lines" in future street-widening zone laws is worthy of consideration for cities where this future need is anticipated. The police power exercised as an incident to present zoning legislation has been limited by Court decisions to future, as distinct from past, activities by the owners of vested property rights both real and personal.

State and Federal Constitutions assure the owner of real property rights that no retroaction laws shall be passed. The claim concerning the effect of destroying vested corner-lot rights in the larger cities by legislating arbitrary destruction of improved property values through the exercise of police powers incident to new zoning laws, as proposed in this paper, is fallacious. The attempted deduction of the legality of thus interfering with vested rights of property owners as being in line with fire and flood prevention, involves the same fallacy as attempting to prove that a dog is a horse for the reason that a dog is an animal and a horse is an animal, hence, they are equal.

It is here submitted that the selection of the decided case of Hayes *et al v.* Hoffman (192 Wis. 63), and the same case (211 N. W. 271, decided in 1927), is not "on-all-fours" with the argument stated by the author for the following reasons stated in a syllabus of that opinion; that is, the Lower Court, upon trial, found that the proposed apartment building owned by the defendant would violate the provisions of the zoning ordinance in overstepping established lines on all four sides of the property. Furthermore, the area to be occupied by the apartment house as well as the area occupied by the defendant's frame house at the rear of the premises, was greater than the maximum permissible area allowed under the terms of the ordinance.

---

[6] Cons. Engr. and Attorney-at-Law, Hastings-upon-Hudson, N. Y.

In its finding, the Court states:

> "It is our own conclusion that the ordinance is, in the respects here considered, a reasonable, valid, and constitutional enactment. It is appreciated that there are other provisions of the ordinance the validity of which may be the subject of future challenge. It is to be understood that no opinion is expressed with reference to any features of the ordinance except such as are herein treated."

The Appellate Court further states (192 Wis. 63) concerning the failure of defendant to plead his constitutional rights:

> "It is the duty of a person who claims that an ordinance invades rights guaranteed by the Constitution to raise that question at his earliest opportunity. Taking part in a proceeding which fixes his liability under the ordinance without raising any question as to constitutionality of the ordinance is a waiver of the right to raise that question subsequently.
>
> "The plaintiffs were given an opportunity to meet this issue (as to constitutionality) in the Court below. The record was made up without reference to that claim made here for the first time. We cannot entertain it."

No attempt will be here made to discuss the author's suggestion under the heading, "The Engineer in Relation to Legislation Concerning Set-Back Lines", or that there is need for engineers to inform Courts as to the enormous cost of putting city streets which are congested by motor traffic in safe condition; nor for engineers to inform the Courts that street relief sought in "set-back lines" is "as much a problem of sovereignty as fire-fighting, quarantine, flood relief, nuisances, etc."

The exercise of the right of eminent domain and the use of recent legislation in street widening through the medium of excess condemnation gives far more assurance of stability to property values and hence to collection of taxes; and if these recognized remedies for the exercise of the sovereign power of the State are properly conducted, the financial relief will be had which Mr. Williams indicates is much needed.

Zoning laws directed to future possible taking of realty for street widening, leave values inert, and the improvement of city street frontage in a stagnant condition. The decided cases are numerous which uphold the contracts that a person makes with the State, or its agencies, such as a municipal corporation. Built-up blocks with narrow streets which require widening, come within the classification of vested rights, the disturbance of which by reason of new legislation under the guise of "exercise of the police power" invites costly and prolonged litigation.

The exercise of the police power and the interference with vested rights of realty owners in connection with zoning laws and city ordinances is discussed by the Court at great length in the recently decided suit of Jones *v.* City of Los Angeles (Cal. Supreme Court, December 31, 1930).[7] The opinion is replete with citations of decided cases and the rules of law controlling the use of the zoning laws, police powers, and the retroactive effect incident thereto. Said the Court, in part, in its concluding statements:

> "No general test can be derived from these or other cases, all of which reiterate the well-worn doctrine that each one must be decided on its particular facts. But we think that there is a decided difference between the ordinance

---

[7] Reported in the *U. S. Daily,* February 2, 1931, p. 8.

which operates to limit the future use of property, no matter how great the impairment of its value, and one which requires the discontinuance of an existing use. * * *

"If the city desires to abolish the non-conforming use, this may be a legitimate object of the police power, but the means of its exercise must not include the destruction of the property interest with compensation. The words of Mr. Justice Holmes in Penn Coal Co. *v.* Mahon, 260 U. S. 393, 413, are very much in point; 'As applied to this case the statute is admitted to destroy previously existing rights in property and contract. The question is whether the police power can be stretched so far.'

"Even where the destruction of private property is warranted by the vital public necessity, it is sometimes the legislative practice to compensate the injured owner. Such was the legislative intent in the eradication of bovine tuberculosis by the destruction of diseased cattle (see Patrick *v.* Riley, 79 Cal. Dec. 379).

"Our conclusion is that where, as here, a retroactive ordinance causes substantial injury and the prohibited business is not a nuisance, the ordinance is to that extent an unreasonable and unjustifiable exercise of the police power."

George H. Herrold,[8] M. Am. Soc. C. E. (by letter).—Establishing set-back lines to create front yards is a common procedure under zoning. They are not difficult to establish because the people like set-backs in residential districts. It is done under the legal fiction of providing light and air and of promoting health and general welfare. Taking a bath is theoretically a matter of personal hygiene, but practically a bath is taken because it makes one feel good; a person likes it. Home owners like set-backs.

Set-back lines for the purpose of widening streets come under a different legal fiction. It is said to be a taking of land for public use without compensation. Mr. Williams' contention is that both are within the field of Government sovereignty; that if set-back lines can be established to create front yards for light, air, health, etc., they can be established for the purpose of widening streets because of congestion; that if limit can be established for the height to which a building can be built by zoning, the ground area used can be limited also. Following this same line of thought, the writer would suggest that, as the speed of vehicles is now limited in congested districts in the interest of safety, it might also be possible to determine and limit the number of vehicles and people that would be permitted to use a given street in the interest of safety.

The street-widening problems of the cities of the United States are staggering. Costs of street widening range from $1 000 000 to $9 000 000 per mile, omitting such projects as Michigan Boulevard and the Wacker Drive, in Chicago, Ill., and the Fairmont Parkway, in Philadelphia, Pa., which cost far more than this. These costs are due to methods of procedure in condemnations. These methods make possible the building up of excessive values for the property to be taken. The values are so great that they absorb the assessments for benefits, legal fees, and other items, and make the citizens at large (through bond issues) pay a profit to the owner. Later, the owner also receives the benefit of the increases in value that always follow a street widening. This method cannot go on.

---

[8] Managing Director and Engr., The City Planning Board, St. Paul, Minn.

The City of St. Paul, Minn., has a retail street, 60 ft. wide between property lines, 40 ft. of pavement between curbs, 10-ft. walks, and a double-track car line occupying 19 ft. of the 40-ft. roadway. Real estate values on this street are the highest in the city. Congestion is intolerable and has been so for years; no more people or vehicles use the street to-day than ten years ago; they cannot because there is no room. Three department stores on this street have aided their own situation by arcading, each placing a 16-ft. walk in their building parallel to the street sidewalk. The Planning Board made a study of the cost of widening this street. It found that if by agreement the property owners would widen the street to 86 ft., each paying his own costs, cutting back his building, putting in a new front, remodeling the interior, building a new 15-ft. sidewalk and paying for widening the pavement 8 ft. in front of his property to create a 56-ft. roadway, the actual cash outlay in round figures would be $1 000 000. The owner would be reimbursed in a few years by the increased value of his property and increased rentals due to his property having greater accessibility on the widened street.

If this street was widened by the City under the power of eminent domain, assessing benefits and damages, the cost would amount to $6 500 000. This is the cost of the present procedure under methods which are common practice where land and buildings are acquired under condemnation proceedings.

Referring again to Mr. Williams' interesting discussion on the use of sovereignty: It takes a long time to change an established legal precedent. This, therefore, seems to the writer to be the proper time to call attention to a proposal made by C. E. Grunsky, Past-President, Am. Soc. C. E., before the City Planning Division of the Society a few years ago. He suggested establishing a building line for widening the street, condemning the strip of land lying between this building line and the street line separate and distinct from the buildings, paying the owners for this land, but compelling each owner to pay the city 6% interest on the amount paid him as long as his building stood on the land. When the owner sets his building back to the new line, he would stop paying interest. In the meantime, the city would have been paying, say, 4½% on the bonds which it floated to pay the owners for the land.

The City of St. Paul has a provision in its charter for carrying out the first part of the procedure, that is, the condemnation of land separate and distinct from the buildings thereon. The objection to using this method is that the owner of the building then has the use of the land for which the city has paid until such time as the Council may take physical possession, and if the City takes possession before the owner has seen fit to set his building back, it must then pay for the building. Mr. Grunsky has thought this idea through to a more logical conclusion, and his proposal is worthy of more consideration than has yet been given it.

Clifford C. Muhs,[9] M. Am. Soc. C. E. (by letter).—The usual legal bias seems to be that the earth was created to demonstrate the beauties of the Illinois statutes. The viewpoint expressed in Mr. Williams' paper is so different from this that it is decidedly refreshing.

---

[9] (Muhs & Co.), Chicago, Ill.

Obviously, the more industrialized (which must also apparently mean the more thickly settled and migratory) a people become, the more surveillance is required to prevent irresponsible parties from taking advantage of their comparative obscurity. Among nomadic peoples anarchy can, and often does, exist as an ideal system. Among pastoral peoples, some faint beginnings of rules of conduct are discernible although there may be nothing more ponderable than public opinion to enforce them.

As civilization progresses, the code of conduct must increase in scope and complexity with a corresponding increase in economic life. It must be extended so as to protect the average person from the ruthless, irresponsible, or obdurate individual whom public opinion cannot now effectively curb.

Legislators, who have more frequently been chosen for their dynamic personalities (real or assumed), have been quick to recognize this trend. If their ability and familiarity with the ordinary economics of life had equalled their zeal, there might now have existed a fairly workable code in spite of the ability of organized minorities to advance their own interest in law at the expense of that of the public.

In the judicial branch of Government the case is different because the candidates are selected for entirely opposite characteristics to such an extent that they might be designated the "high priests of the objectors". To the utter negation of all progress, these objectors seem to abide by the slogan, "Whatever is is right. What has not been done cannot be done." Such men would say that justice is immutable and what was just in Lycurgus' day was just now, ignoring what justice might be essentially.

With such an attitude, legal procedure must always lag a century behind that of its contemporaries, thus becoming indeed the check upon Government it is often proclaimed. Such an apposite as that taken by Mr. Williams is, therefore, the more worthy of lay support, and of such support undoubtedly the most effective should be that of the engineer. The engineer is as little concerned with the past as the lawyer is preoccupied with it, and his hypothesis is that "anything can be accomplished."

In special assessment work the writer has had ample occasion to view the chronic objector in action, even when his interests are being advanced by the project to which he objects and when the compensation in money and enhancement far outweighs the loss.

If then the Bench can be induced to view, with less sympathetic eye, those who see in obstructionist tactics merely another chance to advance their own interests at the expense of others, it will be a consummation devoutly to be wished.

H. B. Cooley,[10] Assoc. M. Am. Soc. C. E. (by letter).—The tendency of the Courts to treat the establishment of set-back lines as a function of the police power of the municipality may be traced through a series of decisions of the Supreme Court of the State of Louisiana.

---

[10] New Orleans, La.

In 1915 (Clavo *v.* City of New Orleans, 136 La. 480, 67 So. 338), and, again, in 1917 (State *ex rel* Blaise *v.* City of New Orleans, 142 La. 73, 76 So. 244), the Supreme Court of Louisiana held that the Charter of the City of New Orleans did not give the Municipal Council the authority to enact a so-called zoning ordinance. The sections relied upon were those which granted the usual police power to a municipality. The following year the Legislature passed an Act enabling cities of more than 50 000 inhabitants to make such laws to regulate the kind, style, and manner of constructing buildings on certain streets and to permit or prohibit the establishment of business within designated limits. The scope of this Act was enlarged and its provisions were extended to all municipalities, regardless of size, by the Constitution of 1921.

Shortly afterward, a case reached the Supreme Court, which originally had been brought under the ordinance declared unconstitutional in the Clavo Case, but which also came under a later ordinance passed after the Act of 1918. On this occasion, the Court held that,

> "If the municipal council had not enacted Ordinance No. 6689 but had relied upon Ordinance No. 5599, we might, in respect for the expressions of the legislature and of the Constitutional Convention, and in the light of recent decisions of the Supreme Court of the United States and of several State courts of last resort, depart from the rulings made in Clavo's Case and repeated in Blaise's Case, and maintain that Ordinance No. 5599 was within the authority granted in the City's Charter and was a valid exercise of the police power".

While it was not necessary for the Court to over-rule its previous decisions, at the same time, it shows clearly a much broader view on the subject of the police power as related to zoning laws. (State *ex rel* Civillo *v.* City of New Orleans, 154 La. 271, 98 So. 440.)

In 1928, the question of a set-back ordinance was raised. This ordinance prohibited the City Engineer from issuing a permit for the erection of a building within 15 ft. of the property line of St. Claude Avenue, one of the principal thoroughfares of New Orleans, between certain streets. The Lower Court declared the ordinance unconstitutional, because the power to enact such a regulation was part of the power of eminent domain, and, therefore, could not be exercised without payment of adequate compensation to the owner for the taking of his property for public use or benefit. The Supreme Court in over-ruling the decision of the Lower Court held that a set-back ordinance does not constitute a taking of private property for public purpose under the power of eminent domain, but, like the so-called zoning ordinances, is merely an exercise of the ordinary police power. (Sampere *v.* City of New Orleans, 166 La. 776, 117 So. 827.)

In the last case the Court cited Gorieb *v.* Fox (274 U. S. 603). A city ordinance of Roanoke, Va., created set-back lines to be at least as far from the street as the line occupied by 60% of the existing houses in the block. In this case the term, "block", denotes that portion on the same side of the street as the proposed building and bounded by nearest intersecting streets to the right and left of the building site. The Supreme Court of the United States held that there was no difference between ordinances prescribing the height of buildings to be erected and the area to be left open for light and air and in aid of fire protection, which have been held valid under the Federal Constitution, and ordinances which required an owner to set back his house a reasonable distance from the street. (In this case the set-back was equal to 34 ft.).

In two recent zoning cases (State *ex rel* Dema Realty Co. *v.* McDonald *et al* 168 La. 172, 121 So. 613; and State *ex rel* Dema Realty Co. *v.* Jacoby 168 La. 752, 123 So. 314), the Court upheld an ordinance which required business to liquidate and move out of the zoned area within one year, as it did not deny defendants of property without due process of law.

In view of the tendency shown by the cases cited, it does not seem a very "far cry" to the time when, as Mr. Williams suggests, such set-backs may be created. Owners of buildings erected over the set-back line will then be given a limited time to move back the proper distance and after that period the property will be used by the municipality under its "police power", for the purpose of handling the ever-increasing and, consequently, more dangerous traffic problem.

WALTER C. SADLER,[11] M. AM. SOC. C. E. (by letter).—This paper is an exceedingly interesting presentation of a proposal to extend the police power of the State to the acquisition of property for the widening of congested thoroughfares. The present discussion will be confined to two aspects of this problem: First, the legal issues involved; and, second, the desirability of such a doctrine.

It is quite clear that the police power has never been used in this type of condemnation of land, or property rights, because all cases of such power bear some element of emergency, where time of action is of the essence. In the case of removal of oyster-bed stream obstruction to stop an epidemic, it is imperative that the obstruction be removed at once without recourse to the slower alternative of applying a suitable chemical to the water. In the case of fire, it is necessary to destroy the intermediate block at once, to prevent the spread of the conflagration; and this is also true in the case of the destruction of gambling devices, to prevent the spread of this vice. Each overt act is taken to prevent a greater harm to the public, with immediate action essential. The nature of the remedy suggested by Mr. Williams bears no such time element of emergency. In fact, the suggested program involves from five to twenty years for securing the proposed result. Surely that period of time is sufficient in which to find some other engineering solution of the problem, such as the construction of an elevated highway, subway, or detour. In other words, the police power of the State is an emergency device with no proper application to a long-term project.

The only justification for the exercise of this power lies in the preservation of public life. Surely it could not be applied to the case of "public convenience", or the doctrine could then be extended to grade-crossing eliminations, etc. If the doctrine is to be applied to the preservation of life, wherein lies the emergency of a remedy twenty years in the future?

---

[11] Associate Prof., Civ. Eng., Univ. of Michigan, Ann Arbor, Mich.

The case of levee work in the South appears to bear out the doctrine suggested by Mr. Williams, but even this group of cases does not seem applicable, for the land there is held under the Napoleonic Code. In that territory, a man holds the property with the understanding that his rights in land are limited in this respect. In the present case of set-back lines, the abutting owners on the congested thoroughfare purchased their property secure in the knowledge that their rights would not be taken without compensation except in emergency cases. The situations are easily distinguishable.

The "zoning case" cited presents a particularly interesting situation. It is a clear case of a taking of property. In fact, it is just as much a taking as though the State had established an easement for highway purposes, the owner retaining the fee. However, the results obtained are due to the peculiar shape of the ground, and its location, and the precedent does not seem to be a very strong one upon which to justify the taking of extensive abutting property rights. Certainly the zoning of 15 ft. on the lawn of a lot in the center of a block would not be suggested as justification for the taking without compensation of that 15 ft. for road purposes.

It is the writer's understanding that Mr. Williams is not trying to establish his doctrine as existing law, but merely as a near step to existing law. The present discussion is offered merely to question the proximity of his doctrine to existing law. It is felt that the taking of property without compensation is quite a long stride.

It would seem appropriate to question the very desirability of the taking of land without compensation. It is certainly shocking to the American concept of property rights. The inviolable nature of property is accepted throughout the land, and the average American understands the essence of the protection. In fact, it is so thoroughly embedded in the American concept of government that should the Courts adopt Mr. Williams' theory and interpret the law as authorizing the taking of this property without compensation, every law-making body in the United States would come to the aid of the abutting land owner.

Mr. Williams has suggested that the problem is an extensive one, involving enormous sums of money, and offers this as a partial justification for the plan. For every square foot of land acquired there must have been an equal amount lost by some individual. The expense to the community is scarcely a justification. In one place it was stated that the cost must be borne by the municipality; that, in the final analysis, the problem is not one of State or Federal concern. The Courts have stated that grade-separation problems are distinctly of State concern. The law itself takes cognizance of this situation. For instance, statutes in New York provide that the State pay 49% of the expenditure and the county 1% in the grade-separation project within a city. Other States contribute in varying amounts. The same relationship should apply to the widening of existing streets used as State trunk lines. It is certainly logical in view of the amount of automobile weight taxes and gasoline taxes, which go directly into the State Treasury. It would appear that the Engineering Profession might do better to sponsor a re-apportionment of the expenditure of these enormous State taxes, than to endeavor to secure legal sanction to the establishment of the doctrine of "taking of property without compensation".

Mr. Williams should certainly be commended for his able and interesting presentation of a proposed solution to a serious transportation problem.

H. J. McFarlan,[12] Assoc. M. Am. Soc. C. E. (by letter).—In this paper Mr. Williams is making an appeal for engineers to lend their influence in convincing the Courts to accept his "new idea, based on the age-old functions of sovereignty". If engineers have and are to maintain any influence it is only because they may have some ability in making an adequate analysis and a reasonable solution of the problems that come to them. It is the purpose of this discussion to consider further the function of sovereignty, to refer in a general way to some of the cases cited by Mr. Williams, to suggest a different point of view, and to submit an argument in its defense.

There can be little question about the right or power of sovereignty to do whatever is necessary for the public good; but there can be many questions as to what constitutes the public good. That the function of sovereignty extends back beyond the time of any formulated expression, is true. In fact, it might be called a "natural" function, first exercised unconsciously when men began to live together, and first exhibited when the power of the group was exercised coercively.

That the widening of streets is a matter of serious public concern is not denied. This admission is also a concession that this problem is a function of sovereignty. More than that, it is agreed that it is a function of sovereignty (and a necessary one) to solve all serious public problems, and that these are rapidly increasing in modern society. Little more than a century ago highway construction and maintenance were not recognized as of public importance. To-day, sovereignty is exercised in varying manner and degree ranging from actual ownership and control of highways to regulation and quasi-regulation of numerous other public utilities.

A change in the nature of vital functions can be foreseen in the future. Many now considered as private, will be recognized as public. If industry is speeded to the point of producing nervous wrecks, sovereignty will intervene. The beginning phase of this is already appearing in safety laws, the regulations of working hours for women, the establishment of food laws, and numerous other types of regulatory measures. If existing economic devices do not or cannot be made to assure the means of livelihood to the masses, sovereignty will re-adjust the devices. These are implications that must be drawn if one is to consider seriously the functions of sovereignty. These are things that the engineer should be concerned about because, unless there is some careful and precise thought exerted, the adjustments are likely to be made in a bungling way. Sovereignty is a "natural" power and Nature has little concern for economy, as men conceive it. If some measure of human economy is to be secured it is by directing sovereignty in such a way that the predictable effect will be desirable. It is the business of engineers working in the physical field to direct forces to the accomplishment of desirable ends. The attempt to interest engineers in getting an understanding of the problems of sovereignty is laudable.

---

[12] Asst. Prof. of Surveying, Univ. of Michigan, Ann Arbor, Mich.

The legal attitude is to seek authority in the shape of precedent to justify a conclusion. Cases in which sovereignty confiscates rather than condemns are cited in support of confiscation for street-widening purposes. It would seem that the analogies between cases cited and the proposed confiscation are not entirely sound. The Fourteenth Amendment to the Constitution of the United States is a formulation of a principle that was recognized before constitutions, as being necessary to the continuance of law. The demand on the part of laws for socially acceptable conduct is not in contravention of that principle. Neither can it be expected that by law one can be protected against the vicissitudes of Nature. It is true that as society has become more complex there has been a growing tendency toward restricting the use of private property. If an increase in social complexity makes it necessary seriously to restrict, or to confiscate, as a common thing, sovereignty may re-adjust values to the extent that all rights in property may become social.

The taking of property for street widening would seem a step in this direction. It does not seem analogous to the prevention of fire, flood, or disease, and even seems somewhat different from zoning. The precedents cited are of two classes. One is of the emergency type due to a condition caused by what is known in law as "an act of God." The other is a demand for socially acceptable conduct. There is great necessity when a building has to be destroyed to save the spreading of fire. The right of a quarantined man to expose the community is frowned upon socially. The right to build a factory in a residence district is also denied. As will be argued subsequently, social insurance for the unfortunate ones suffering loss might not be unreasonable. If a set-back line is established before property is developed, this is of the nature of zoning. This, in effect, is done now through the power exercised by planning boards. No one arguing for zoning would be so bold as to suggest the destruction of factories to provide a residence district. The demand for socially acceptable conduct is vastly different from upsetting values that have accrued through legitimate use. The proposed confiscation is not necessary because of an accident of Nature, it is not a demand for the regulation of conduct (in an active sense), and it is fraught with dangers because the "when" and "where" of its being practiced is within the control of men. This latter fact also makes it different under the "equal rights" law from all the cases cited, except perhaps zoning, and that is not retroactive, so to speak, against improvement.

The business of the engineer is to conceive the desirable and then to set about to find ways and means of accomplishment. He does not ignore prejudice and precedent, because an account of these must be taken in making his evaluations. Neither does he accept what has been done as authority for new endeavors. To him the worth of an idea is dependent upon the effect it will have. This is what is known in the terminology of modern writers on the philosophy of science as the operational point of view. This is the point of view that has speeded the production of the marvelous creations of modern science. It is responsible for deliberate invention in contrast to accidental discovery.

It is true that an engineer works in the so-called field of the exact sciences. It does not follow, however, that the operational point of view cannot be held when dealing with problems that have to do with human reactions. Indeed, the difference between the two fields of endeavor is due probably only to the difference in precision with which the data are obtainable. One frequently reads or hears an appeal made for the engineer to lend his aid to the solution of some grave problem. If he is to have an effectiveness comparable with what he has had in the solution of his own problems, it will be because he carries over his scientific type of thinking to this other field. It is not conceivable that he would be likely to be more successful with lawyers' law, sociologists' sociology, or economists' economy than men who have made these studies their life work. It is within the realm of imagination, however, to think that the engineer—because he is active in a field that demands that the worth of an idea be tested by the effect it has—may be able to lend valuable aid to those engaged in the solution of social problems. Unless he is cognizant of the philosophy of science, he is likely to lend his support upon recommendation of the specialists in the other fields, and thus bring no more influence to the solution of the various problems than any other citizen.

The burden of the argument in favor of confiscation has been carried by a citation of precedent, aimed at persuading that the solution is in a realization of the fact that it is a problem of sovereignty. It seems like a begging of the question to assume that confiscation is the only remedy that sovereignty suggests.

The engineer, when called upon to attempt the solution of modern traffic problems, must consider all factors of the situation. He may doubt the wisdom of widening as a solution. He certainly can foresee that there are limits of the extent to which widening may be carried out. He must think about the feasibility of decentralization and its economic consequences. Granted that confiscation might expedite the widening programs, the engineer realizes that this might not be unmitigated good. There are limits beyond which almost any developmental change cannot be made to economic advantage. Congestion in crowded districts is already leading in a natural way to the development of new business areas in many cities. Therefore, engineers who are aware of their social responsibilities should not be misled into developing an enthusiasm for a point of view which apparently considers only one phase of the problem. The necessity for confiscation is predicated upon the fact that taxation and the management of municipal units (where the bulk of the burden would fall) are such that the resources for compensation under condemnation are not available. Possibilities for the exercise of sovereignty by means of taxation are without limit, except that taxes be made so great as to absorb all private values in property. A remedy for the municipal financial situation might be suggested as a solution of the problem under discussion.

It seems that "in the long run" the practice of condemnation would prove to be more equitable. In effect, this practice involves an insurance element. All citizens unite through the taxation system and agree to compensate those who have located where society later decides they are in the way. It would seem that an extension of the idea of compensating those who are caused to suffer loss for the public good by fire, water, or disease might be in the direction of justice. The question of accrued values occurring as a result of widening is another and broader one. Undoubtedly, many properties adjacent to widening appreciate in value without suffering any loss. The entire question of rights in property is involved. An unlimited extension of the idea of confiscation would lead to a reformulation of the principles which guarantee security in the possession and use of property. This unlimited extension of confiscation may be as logical a step as that from quarantine to street widening.

It is necessary to stop and consider desirability by making an estimate of effect. When land is taken for street widening there is a loss of that land for other uses. The question is whether that loss shall be borne by the freeholder or by the social group that needs the wider street. Confiscation would not remove the financial problems; it would merely shift the burden. Faulty taxation or abuses under existing practice do not necessarily argue for confiscation. Perhaps good arguments can be given, but it would seem that the author of this paper has not presented them. Until the effect of the proposed solution is injected into the argument and until engineers are convinced that all other possible solutions are by comparison not as good in effect, it should not be expected that they will respond to the appeal made to them.

DONALD M. BAKER,[13] M. AM. SOC. C. E. (by letter).—The theory advanced by Mr. Williams is interesting, but if it were generally adopted it might establish a dangerous precedent; and, through an extension of the same theory to similar subjects, it might lead to rather alarming consequences. The theory advocated is that narrow streets in the present age of intensive operation of motor-driven vehicles are dangerous to public health and safety and that the governing agency should be able, by giving proper notice to the owners of abutting property of its intention, to take sufficient of this abutting property, at some future date, to make a highway of a width adequate to satisfy traffic demands, this taking to be without compensation to the owners.

Narrow streets in themselves are not dangerous to public safety. On the contrary, due to their very narrowness, traffic is deterred from using them. Wider streets attract more and faster traffic; in fact, they invite traffic of a nature which is more likely to become dangerous to public safety through accidents than that occurring on narrow streets. As to public health, there are data pointing to the fact that on narrow streets lined with tall buildings the health of the users thereof, and particularly that of the occupants of buildings on adjoining property, may be somewhat affected by carbon monoxide (CO) given off from the exhausts of automobiles. Evidence on this point, however, is not conclusive. Narrow streets do cause a clogging of vehicular circulation, but this affects primarily the values of the adjacent property, and it alone suffers. Without adequate opportunities for circulation, activity moves elsewhere and values depreciate.

---

[13] Cons. Engr., Los Angeles, Calif.

If the principle advocated by the author were generally adopted by the Courts it might lead to a wholesale taking of property for public purposes without compensation. Consider, for example, the case of a badly congested neighborhood where there is urgent need for a playground. Such need might be just as severe from the standpoint of public health and safety as the need for wider streets. Under the principle advanced, the governmental agency could state that at a date five or ten years in the future it proposed under its sovereign powers to take property necessary for this playground from the owners thereof, without compensation. In the meantime, the owners must adjust themselves to the inevitable, being warned that any improvements or alterations made upon the property would be made at their own risk. It would be a simple matter in time to extend this principle to the acquisition of all property needed for public purposes.

The illustrations of the exercise of sovereignty, cited by the author, are emergency cases for which no other remedy is available. When buildings in the path of a fire are dynamited to stop the approach of a widespread conflagration, in all probability they would have been consumed by the fire in any event. The exercise of the right of quarantine is the only present feasible way of stopping an epidemic. It is an emergency measure. Property as represented by gambling devices may be seized because, in general, such devices are owned in violation of the law, and the owner may not come into Court with clean hands to reclaim them. The extermination of nuisances falls in a different category. If the nuisance existed before the surrounding development was made, the promoters of this later development would be forewarned of it and, in some cases, would have no remedy. If the nuisance commenced after the surrounding area was developed, the party causing the nuisance was forewarned and instituted it at his own peril.

The only reason for the establishment of set-back lines for future street widening is that it would be uneconomic to make the widening at the time the set-back lines were proposed. Either traffic needs are not sufficient at present to require it, or its cost would be such that the property assessed for the widening, be it a district or the entire city, could not afford to pay the resulting price. In other words, the benefits resulting from the widening would not equal the cost thereof. In the first instance, it is a perfectly proper procedure, which should be supported by the Courts, to establish lines beyond which no owner may build and expect to obtain future damages for the destruction of that portion of his building extending beyond the line. This procedure is a wise one and prevents the public from being subjected to excessive and unwarranted damages when widening occurs. However, if the public is not in a position to pay for the land at the time the set-back lines are established, the owners should be compensated for the land taken, at such time as the project becomes feasible and economical.

The writer also disagrees with Mr. Williams as to the general enhancement in values which result from a street widening or opening. It is true that such enhancement in value does occur in some instances where a portion of a parcel of property has been condemned, but this is rather the exception than the general rule. In many cases the widening and improving of a street with the resultant increase in traffic causes an actual detriment to the owners of abutting property, with the benefits, if any, accruing to property on side streets, which streets achieve greater accessibility without being injured by increased traffic.

City planners have established through investigation a definite relationship between business frontage and supporting population. With the present density of motor-vehicle traffic it is absolutely impossible to fill up the frontage on all the major traffic arteries with business. It is only in locations where business is justified and warranted that a resulting enhancement in values will occur. The widening of a quiet residential street into a heavily traveled artery will ruin such street for single-family residential use unless the property abutting thereon is developed into rather large holdings where the residences can be well set back from the property line, masked by shrubbery, hedges, etc., and thus screened from resulting confusion, noise, and dust.

Furthermore, such traffic arteries are not desirable for multiple residential or apartment-house purposes. Resulting noise, dust, etc., occasioned by heavy traffic makes the construction of these buildings—unless they too can be screened effectively from the traffic—an economic impossibility. The general effect of an extensive street-widening and improvement program, taking into consideration all the property involved, is a "freezing" of a considerable proportion of the frontage thereon. It cannot all be used for commercial purposes. In many cases, it is unsuitable for multiple residential or apartment structures, and entirely unsuitable for single-family residential uses. This has been the actual experience in Los Angeles, Calif., during the period from 1927 to 1930.

There is no question but that traffic congestion caused by the rapid increase of motor vehicles requires drastic remedies, but these remedies lie more along the lines of proper planning and budgeting of the program of street widening, proper methods to be developed for the allocation of costs, more aggressive opposition on the part of city authorities toward unduly high awards in condemnation proceedings, and greater realization on the part of the Courts that excessive awards will prevent the ultimate achievement of a satisfactory and necessary arterial traffic plan, rather than in the adoption of the principle suggested by the author. Acquirement of adequate traffic capacity solely at the expense of abutting property is not just, because usually not the abutting property, but the entire surrounding district, is benefited, and the district should contribute toward the benefits received. If these benefits do not justify the cost, then the project is uneconomical and should not be attempted.

E. G. WALKER,[14] M. AM. SOC. C. E. (by letter).—The new idea offered in this paper involves rather drastic action. There can be no question of the correctness of the basis upon which the author ultimately relies; namely, that, in an emergency, the community as a whole has the right to interfere with private rights and to upset them completely if necessary in the interests of the people. However, in stretching his analogies of fire-fighting and quarantine to make them the bases of proposals for a drastic alteration of the existing principles of dealing with street widening, the author is not completely logical.

---

[14] (Maxted & Knott), London, England.

Conflagrations that make it necessary to enter private land and destroy buildings and other property thereon, and epidemics that require the isolation of all individuals coming from an infected area, are both subjects which are but partly under human control. Drastic curtailment of individual liberty entailed by remedial measures to which the author refers in his paper are brought about for that reason.

On the other hand, the regulation of traffic is under the entire control of the authorities appointed to deal with it. There is, therefore, no more reason for expropriating private property in one place than there is in another. If a particular road becomes too congested the traffic can be diverted to another one, or new roads can be built through less congested areas to by-pass traffic which is not proceeding to a destination in the area. The logical outcome of the author's suggestion is that any land required for road development could be expropriated without compensation. It would then follow that any property required for any purpose—which any State or local government that happened to be in power at the moment might consider to be in the interests of the community—could also be expropriated without compensation.

There is certainly much to be said against the huge and frequently inflated values which are assessed upon property taken for street widening in congested areas. There is room for considerable improvement in making the assessments. The argument that has been advanced frequently, is that these values belong in great part to the community because, but for the activity of the community, central sites would not reach such high values. Attempts have been made in the past to appropriate to the community such proportion of the increase of value of property sites as could be claimed to be due to general communal development. These have failed primarily because of the impossibility of assessing any value for a site independently of the existence and activities of the occupants of surrounding sites.

The problem of taking land for road widening is full of difficulties and can be solved only by having reasonable regard to the interests of the individual as well as to those of the community as a whole. The suggestion that property should be taken without any compensation whatsoever is much too drastic. It is as unfair in one direction as the influences which frequently are brought to bear to enhance values for compensation, are in the other direction.

SYNOPSIS

This Symposium constitutes the final professional record of the construction of the 7.79-mile Cascade Tunnel by the Great Northern Railway Company. It is presented in three parts, each part being written by an official of the Great Northern Railway Company, or of A. Guthrie & Co., Inc., the contractors on this work.

Part I, by Mr. Kerr, is an outline of the history of the Great Northern Railway line over the Cascade Mountains in the State of Washington. It also contains a discussion of the reasons leading to the improvement of this mountain crossing.

Part II, by Colonel Mears, contains a description of the surveying methods and instruments used in constructing the tunnel. It presents the general plan of attack, the construction standards, and a description of the line improvement on the east and west slopes of the Cascade Mountains; and it gives a comparison of the physical characteristics of the new and old routes.

Part III, by Mr. Baxter, with two appendices by H. J. King, M. Am. Soc. C. E., is a study of the plans made for the tunnel and the detailed problems affecting methods of construction.

PART I.—PRELIMINARY STUDIES AND RESULTS OF IMPROVING CASCADE CROSSING

BY D. J. KERR,[2] M. AM. SOC. C. E.

The Great Northern Railway, while not the most recently built transcontinental line, was only opened through to the Pacific Coast in January, 1893. It was in December, 1889, that John F. Stevens, Past-President and Hon. M. Am. Soc. C. E., explored the Marias Pass in the Rocky Mountains and thus opened up a short and low summit route for a line not far south of the Canadian border. Mr. Stevens did not have the satisfaction of staying to complete the location survey over the Rockies because his success there resulted in the late James J. Hill, F. Am. Soc. C. E., sending him to the Cascade Range to determine the route of the Great Northern Railway across that barrier.

In 1890, there was little information available about the Cascade Mountain passes in Northern Washington, and the slopes were heavily timbered. The route to the sea by way of the Fraser River in British Columbia and by way of the Columbia River along the boundary between Washington and Oregon had been known to white men for nearly a hundred years. The Northern Pacific transcontinental line, opened in 1887, followed the Valley of the Yakima River (see Fig. 1) from its confluence with the Columbia, near Pasco, Wash., and crossed the Cascade Range through the Stampede Tunnel to the head-waters of Green River, and thence down the Green River Valley to the Pacific Coast.

Mr. Hill, as he had done across Dakota and Montana, wanted the line across the State of Washington to open up new territory, and Mr. Stevens proceeded to make a thorough examination of the Cascade Range between the Northern Pacific crossing and the Canadian boundary, a distance "as the crow flies" of 125 miles. A reference to the map, Fig. 1, will make the problem and the description clearer.

The result of Mr. Stevens' work was the selection of a pass which connected the head-waters of Nason Creek, a tributary of the Wenatchee River, with Tye River, a tributary of the Skykomish River. The Wenatchee River joins the Columbia River near Wenatchee, Wash., while the Skykomish flows into the Snohomish which enters the sea at Everett, Wash. The route, therefore, was fixed from Spokane, Wash., *via* Wenatchee, the new pass (since known as Stevens Pass), and Everett; thence, 35 miles along the seashore, to Seattle, Wash.

The pass had an elevation of 4 059 ft. The approach from the east was through the narrow Tumwater Canyon of the Wenatchee River and on the west side the slopes fell away so rapidly as to necessitate considerable development to obtain a reasonable grade line. Mr. Stevens selected 2.2% as the maximum grade of the permanent line which was to be located down hill on each side from the portals of a projected tunnel, 2.7 miles long. The summit was to be at the east portal of this tunnel at an elevation of 3 383 ft.

---

[2] Asst. to Vice-Pres., Operating Dept., G. N. Ry., St. Paul, Minn.

The Great Northern Railway Company had no land grant west of Minnesota, and it was necessary to develop traffic quickly to justify the construction of the extension. The opening of the through line could not be delayed awaiting the completion of a tunnel nearly three miles long and, therefore, a switchback route with 4% grades was located over the mountain across the open pass and connecting with the permanent line near the portals. This switchback route served to handle the through traffic of the Railway Company from January, 1893, until December, 1900, when the 2.7-mile Cascade Tunnel was completed. As a result the summit elevation was reduced from 4 059 to 3 383 ft., and all grades heavier than 2.2% were eliminated. The profile of the line from Wenatchee to Skykomish, Wash., is shown in Fig. 2.

FIG. 2.—MAP AND PROFILE, SHOWING OLD AND NEW MAIN LINES BETWEEN APPLEYARD AND SKYKOMISH, WASH

There was little evidence of snowslide trouble on the heavily timbered slopes along which the line located by Mr. Stevens lay, but the destruction of timber above the railroad by fire soon altered the situation. Snowslides of increasing extent developed and the need of protection became apparent as early as 1903. Nearly every year thereafter it was found necessary to extend the snowshed protection. The record of annual snowfall between Leavenworth, Wash., and Skykomish (that part of the line above Elevation 1 000) is of great interest; this record is shown graphically in Fig. 3. Particular attention is called to the heavy snowfalls during the winters of 1909-10, 1912-13, and 1915-16.

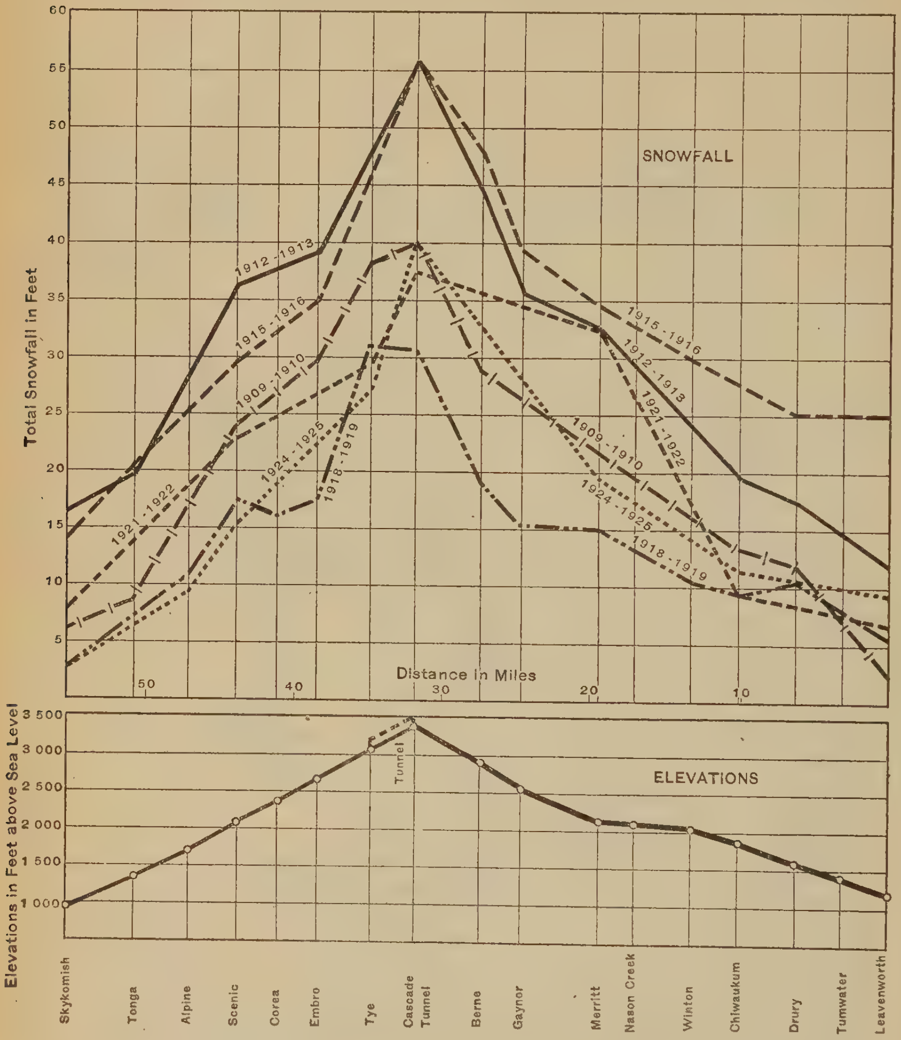

FIG. 3.—RECORD OF ANNUAL SNOWFALL BETWEEN LEAVENWORTH AND SKYKOMISH, WASH.

The sections of the line exposed to snowslide menace were rather limited and consisted of two districts—one on each slope. On the east slope the trouble was confined to the line through the Tumwater Canyon between Leavenworth and Winton, Wash., a distance of 13 miles; on the west slope the trouble zone extended from the west portal of the old tunnel to Scenic, Wash., a distance of 12 miles. The rapidity with which this menace developed and extended is shown best in Table 1 which gives the number of linear feet of track protected at the end of each year.

TABLE 1.—LINEAR FEET OF LINE PROTECTED AT THE CLOSE OF EACH YEAR

Year	TUMWATER CANYON, LEAVENWORTH TO WINTON	CASCADE MOUNTAIN CROSSING, MERRITT TO SCENIC	
	Sheds	Sheds	Tunnels
1903	.....	3 894	15 595
1905	.....	4 833	15 595
1907	.....	7 044	15 595
1909	.....	7 638	15 595
1911	1 429	14 766	15 595
1913	2 022	25 877	15 595
1915	2 022	26 221	16 816
1917	8 401	32 033	19 332
1919	8 401	32 412	19 332
1921	8 401	32 420	19 332
1923	8 401	32 313	19 332
1925	8 401	32 322	19 332

The earlier snowsheds constructed before timber and labor costs had advanced as they have in recent years, were built for about $70 per lin. ft. for single-track and $83 per lin. ft. for double-track sheds. Those constructed with concrete back-walls and timber roofs cost $175 per lin. ft. of double-track shed. Many of the roof timbers were 24 in. by 12 in. by 42 ft., and such timbers are now high in price and increasingly difficult to obtain. At present prices, a double-track concrete back-wall shed, with a timber roof, costs almost $210 per lin. ft.

The increasing cost of replacement and the constantly increasing length of line requiring protection caused considerable thought to be given to the finding of a route that would avoid the snowslide areas entirely. Studies were made from time to time by the late A. H. Hogeland, M. Am. Soc. C. E., and by O. S. Bowen, M. Am. Soc. C. E. A most complete study of the problem was made by Mr. E. J. Beard in 1917, which not only compared the relative economies of a long tunnel line with the existing line from the standpoint of the cost of maintenance and construction of snow-sheds, but also from the standpoint of the transportation savings from the shorter, lower summit and easier grade line, coupled with electrification.

The conclusions reached by Mr. Beard in 1917 are summarized, as follows:

"That the present line in Tumwater Canyon, Leavenworth to near Winton, and from Merritt to Skykomish, be abandoned, substituting therefor changes in line by which all snowsheds are avoided, providing either a 1.4% or a 1%

ruling grade and involving either a 14½ or a 17¼-mile tunnel, as chosen, and estimated to cost, including the changes, electrification, Leavenworth to Delta, necessary equipment, and 100-lb. rails, $25 000 000 or $27 000 000.

"This, because the present line, if retained, will have to be electrified some day, when the cost, plus the great expense that must be incurred account of snowsheds, existing and additional, would be $21 000 000, an investment that would make the property for years less profitable than it is at present; *per contra* the undertaking first above will, upon completion, increase net corporate income over that with the present line, electrified, about $350 000 per year, and the advantageous difference will increase each year.

"That neither the present line, steam operated or electrified, nor the undertaking first above should be double-tracked, because the surplus train capacity of either is enough for the increase in traffic of so many years in the future that no money whatever should be spent for, or in anticipation of, double-tracking.

"The present snow-sheds, with the minimum of additions that circumstances will permit—to be built of timber—be maintained at the least practicable cost until the undertaking first above is completed.

"That every effort be made and consistent expense be incurred to complete the undertaking first above in from 4½ to 5 years instead of the estimated 6½ to 7½ years, thereby reducing the estimates above by from $1 500 000 to $2 000 000."

Unfortunately, the intervention of the World War forced the project into the background and at the conclusion of the war neither the traffic nor the financial condition warranted the consideration of a large project. The full effect of the Panama Canal on transcontinental rail traffic was only felt as ship tonnage became plentiful in 1919 and 1920.

Discussion of the project was revived in 1921, and new estimates were made from that time until 1925. These were based largely on the 14-mile tunnel line recommended by Mr. Beard. By that time costs had changed materially and it was evident that the project would involve an expenditure in excess of $30 000 000. Such an outlay could not be justified economically at that time and, having reached the conclusion that a long tunnel would not be built, the Operating Department of the Railway Company began the improvement of operation over the existing line.

In earlier days trains were moved eastbound from Skykomish by coal-burning locomotives with the result that the atmosphere in the old tunnel (which was on a 1.69% grade against eastbound traffic) was intolerable. In 1909, a hydro-electric development was made in the Tumwater Canyon, a short distance above Leavenworth, and plans were begun for electrifying the tunnel.

The Tumwater Plant consisted of three 2 500-kw. units and power was transmitted to the tunnel at 33 000-volts, 3-phase, 25 cycles. The overhead trolley installation consisted of two 4-0 wires, carrying 6 600 volts, and extended about 3½ miles from Cascade Tunnel Station through the tunnel to Tye, Wash. Four 3-phase locomotives were purchased which had constant speed of 15 miles per hour, that being the only running speed available. The plan of operation was to have a train of about 2 000 tons leave Skykomish with a steam road engine and two steam pushers. At Tye (the west portal of the old tunnel), the train was cut in two and, with the road engine, was taken through to Cascade Tunnel Station (the east portal of the old tunnel) by electric locomotives.

The first move made in 1925 to improve operation was to re-arrange the electric locomotives so that the traction motors could be connected in cascade giving the locomotive when so connected a speed of 7.5 miles per hour instead of 15 miles per hour. This change permitted taking passenger trains through the tunnel at 15 miles per hour as before and freight trains in one section at 7.5 miles per hour. In this way the full power available at Tumwater (the only source) was used, and the tractive effort of all four locomotives was made useful for freight trains.

The success of this change prompted the Company to consider extending the electrification down the west slope to Skykomish, with the idea of using electric pushers throughout. The plan was to obtain two electric locomotives which, with steam engine working, would move a train from Skykomish to Tye on a 2.2% grade and which could haul the train and the steam road engine (not working) from Tye to the Cascade Tunnel through the old tunnel on the 1.69% grade.

The limited supply of power available at the Railway Company's Tumwater Plant and the need of variable-speed locomotives to work with steam road engines resulted in the selection of the motor generator type of locomotive with 11 000-volt, single-phase, 25-cycle trolley, and 600-volt, direct-current traction motors. Two such double-cab locomotives (each having a 1 500-kw. motor generator set) were ordered in 1925, and work had already been started on the electrification of the old line, when serious consideration was given again to the long tunnel plan.

The success of the operation of freight trains in one section through the old tunnel, the improvement in steam operation (which had permitted running freight trains through from Seattle and Everett to Wenatchee in less than the 16-hour crew limit), and the failure of the through freight traffic to show a material increase, made it apparent that savings in transportation expense alone could not justify any long tunnel line and that if such a project were to be warranted economically it must be the shortest tunnel which would permit the abandonment of all the line on the west slope subject to the snowslide menace.

A study made by Frederick Mears, M. Am. Soc. C. E., showed that this could be accomplished by a tunnel 7¾ miles long, having its east portal at Berne, Wash., and its west portal at Scenic. In contrast to the 14 or 17-mile tunnels recommended by Mr. Beard, this plan did not eliminate the 2.2% grade, but left in use the five miles of such grade against westbound traffic between Merritt, Wash., and Berne and eleven miles against eastbound traffic between Skykomish and Scenic.

Mr. Stevens was called upon to go over the ground that was so familiar to him and as a result of an exhaustive study in the summer of 1925, he urged the immediate approval of the 8-mile tunnel line as the only project that could be justified. He pointed out that there was much unwarranted prejudice against pusher districts and that with electrification the former objection to sections of 2.2% grade was largely eliminated, especially when such grades were comparatively short. Accordingly, the Board of Directors of the Railway

Company reached the conclusion in November, 1925, that the 7.79-mile tunnel should be built.

As a distinct and separate project on the east side of the mountains, a new line (the Chumstick Line) was projected from Peshastin (near Leavenworth) to Winton, Wash., a distance of 17 miles. It followed the open Chumstick Valley, eliminated all 2.2% grades east of Merritt, and provided a line with 3° maximum curvature, entirely free from the snowslide menace to which the old line in the Tumwater Canyon was exposed.

In addition to the major improvement made by the construction of the Chumstick Line on the east slope, numerous short sections of the old line between the west end of the Chumstick Line at Winton and the east portal of the new tunnel at Berne, were improved in alignment and grade.

When the decision to build the new tunnel was reached in November, 1925, the age of the existing snowsheds made it extremely important, if heavy renewals were to be avoided, that the new route be made ready for use before the snowslide season of 1928-29. To avoid delay, the firm of A. Guthrie & Co., Inc., of St. Paul, Minn., was instructed to proceed with the work on a fixed fee basis—a plan which later was extended to cover the construction of the Chumstick Line.

The need of an adequate supply of power for the driving of the new tunnel made it advisable to turn over the Company's power station at Tumwater to the Puget Sound Power and Light Company and to contract with that Company for power to be supplied from its widespread system. Having such power available brought with it the decision to electrify the entire district from Wenatchee to Skykomish (75 miles).

These four pieces of work (1) the 7.79-mile Cascade Tunnel; (2) the Chumstick Line; (3) line revisions between Winton and Berne; and (4) the electrification from Wenatchee to Skykomish, constituted a complete program for the improvement of the Cascade crossing.

The first, in addition to the improved alignment and lower summit obtained, permitted the abandonment of all the line on the west slope subject to snowslides; the second, which also improved alignment and grade, resulted in the discontinuance of operation over all that part of the line on the east slope subject to slides; the third resulted in a marked improvement in grade and curvature; and the fourth was a necessary step following the decision to build the long tunnel and to avoid too frequent locomotive changing.

The completion of the program has put the Cascade crossing on an equal footing with the remainder of the main line in character, freedom from interruption, and freight-train tonnage that may be handled.

A comparison of the old and new line from the east end of the Chumstick revision, at Peshastin, to the west end of the tunnel revision at Scenic, is given in Table 2.

The electrification program, together with the change in line, grade, and rise and fall indicated in Table 2, has permitted the operation of 5 000-ton freight trains eastbound out of Skykomish, using a three-cab road locomotive and a two-cab helper. These helpers are operated generally between Skykomish and Merritt—the foot of the 2.2% grade on the east slope—thus avoiding any stop at the summit at Berne. Westbound, in ordinary operation, the three-cab locomotive takes a 3 500-ton train from Wenatchee to Merritt, where a one or two-cab helper, whichever may be available, is used to Berne and remains in the train on the down-hill slope to Skykomish. As compared with the steam operation prior to any electrification on the slope west of the old tunnel, the train tonnage eastbound has been increased from 2 400 to 5 000. The average time for a freight train between Skykomish and Berne has been reduced 3½ hours and the gross ton-miles per train hour between Skykomish and Wenatchee have been increased from 11 520 to 70 000. The traffic on this part of the line is prevailingly eastward, substantially in the proportion of 5 000 to 3 000 tons.

TABLE 2.—COMPARISON OF OLD AND NEW LINES

	Old line.	New line.	Favorable to new line.
Length, in miles	49.32	40.90	8.88

Total degree of curvature	5 617° 34′	2 059° 06′	3 558° 28′

* Unfavorable to the new line.

The various steps in the improvement of the railroad between Wenatchee and Skykomish have so overlapped that it is impossible to divide the savings resulting from the entire project into the part due to electrification and the part due to the improved alignment, lower summit, shorter mileage, etc. These savings in the aggregate are not more than sufficient to pay interest on the entire investment. The Railway Company must look for the justification of the project to the benefit which the system as a whole has received through the elimination of a weak link in its transportation chain, with consequent increased traffic resulting from service that is absolutely dependable, quicker, and, in the case of passenger travel, extremely comfortable and pleasant.

PART II.—SURVEYS, CONSTRUCTION METHODS, AND A COMPARISON OF ROUTES

BY FREDERICK MEARS,[3] M. AM. SOC. C. E.

Surveying parties were put into the field on the west slopes of the Cascades in September, 1925, to locate a line that would meet the general requirements of the problem, which called for reduction in curvature, saving in distance, and permanent protection of the line against snowslides. From a study of the United States Geological Survey maps of the Cascade Range, and other engineering data available, it was apparent that a tunnel approximately eight miles in length would meet these requirments, with east and west portal near Berne and Scenic, respectively.

The line adopted provided for a single-track tunnel, 7.79 miles in length, on tangent, with 0.74 mile of new line approaching from the east and 1.54 miles from the west.

West Slope.—The locating party on the west slope made a detailed survey of the country in the Tye River Valley above Scenic, to determine suitable portal sites and proper gradients for the west approach, two portal sites in particular being developed, as shown by Fig. 4. Close topography was taken and soil and rock conditions were noted. The existence of a 0.99% grade on the main line, throughout the length of the old Scenic passing track, made it possible to raise the grade of the new line without exceeding the maximum 2.2% grade, so that 1½ miles of new embankment could be constructed on the floor of the Tye River Valley leading up to the face of the mountain.

The Cascade Range is in a region of high precipitation, particularly in the fall and winter months. Several hot springs were known to exist on the mountain slopes above Scenic, and every precaution had to be taken to locate the portal and approaches to avoid menace from snowslides, as well as to secure proper drainage.

The south slope of a ridge, in a bend of the Tye River, affording sufficient cover to "portal under" was finally selected as the west portal site, as shown in Fig. 5. The approaches were free from snowslides, and the Tye River provided good drainage for surface and underground water. It was known that the westerly ½ mile of the new tunnel would lie in a somewhat broken formation, requiring heavy timbering while in course of construction, but it was impossible to better this ground condition and, at the same time, meet other requirements.

East Slope.—On the east side of the Cascade Range, a portal site was located, as shown in Fig. 6, which met every requirement. A solid rock face of a mountain slope was selected for the portal, which could be reached from the operated line by the construction of less than a mile of new line, on good grade and alignment. This site was free from snowslides or drainage problems.

---

[3] Asst. Chf. Engr., G. N. Ry., Seattle, Wash.

Open Traverse.—As soon as the east and west portal sites were decided upon, a preliminary survey was made to connect the portals. This was an open traverse, about 10 miles long, following the operated line. (See Fig. 4.) The traverse showed that the tunnel would be on approximately a 1.6% grade, descending from east to west, and that the open approaches, at either end of the tunnel, could be built on a 1.5% grade, to provide for passing tracks of suitable length near the portals.

FIG. 4.—MAP SHOWING PRELIMINARY SURVEYS FOR NEW TUNNEL THROUGH THE CASCADE RANGE.

The preliminary traverse was extended up the valley of Mill Creek, and detailed surveys were made which developed that an intermediate shaft site could be located in the Mill Creek Valley, which would have the proper relation to the east and west portals and to the sub-grade of the proposed tunnel.

The floor of the valley of Mill Creek, where it is crossed by the axis of the tunnel (see Fig 7), was found to be about 622 ft. above the proposed tunnel sub-grade, at a point 2.41 miles west of the east portal. A shaft site, therefore, was laid out on the west slope of the valley, which will be referred to later. The relative location of this shaft is indicated on Fig. 8.

Second Survey.—Before establishing the tunnel tangent on the ground, a second survey was made, using more precise methods, but following very closely the first open traverse.

The azimuth of the long tunnel, calculated from this second traverse, was thrown across the four mountain ridges intervening between the portals. A light mountain type of transit was used in this field work and the error of closure between this first location of the tunnel axis and the open traverse, which followed the heavy curves of the operated line, was about 6 ft. The line thrown across the mountain tops was accepted as the preliminary tunnel axis, and the 8 by 9-ft. pioneer tunnel at the west portal, and the 10 by 10-ft. center heading at the east portal, were started by reference to it.

PRECISE SURVEYS OF THE LONG TUNNEL

The field work for the "definite location" of the New Cascade Tunnel, including the precise location of the intermediate shaft, in the rugged mountains of the Cascade Range, was an interesting problem, in which the following fundamental steps were involved:

> *1.—Alignment.*—The establishment of the tunnel axis across the mountain tops between portals, and the accurate projection of this line into the Valley of Mill Creek at the shaft site.
>
> *2.—Distance.*—The measurement of the tunnel axis and the determination of the exact position of the Mill Creek shaft with respect to the east and west portals.
>
> *3.—Grade.*—The determination of the difference in elevation between the east portal and the west portal and the mouth of the Mill Creek shaft.

Establishing the Tunnel Axis.—The first location of the tunnel axis across the mountains was made in December, 1925, using light, mountain-type transits. This was followed very shortly by a second survey conducted in a manner to secure greater accuracy. Precise transits of a larger type were used on this second survey, which were equipped with 11-in. telescopes of 28 power and horizontal plates, 7 in. in diameter, graduated to 10″ of arc. Several lines were run with these transits. The first operation showed that the preliminary tunnel axis established by the mountain type of transit was not a truly straight line; it contained a small constant error in the same direction, causing the line to follow a curve, with the east and west portals of the tunnel at either end. A "chord" to this curve, extending from portal to portal, was then calculated, and the offset distance determined for the two intermediate set-up points, at "Cowboy" Station and at "Big Chief" Station. (See Fig. 9.)

These two stations were then used to form a base line, from which the axis of the tunnel was produced toward the east portal and toward the west portal. Several trials were necessary before determining the exact points on Cowboy and Big Chief Mountains.

When the line had been refined by the precise transits to a degree such that it was considered safe to construct concrete monuments at the several observation points (seven in number, see Fig. 9), a high-power telescope direction instrument was used in the final adjustment of the line. Fig. 10 illustrates the type of instruments used for various parts of this work. As an ordinary tripod would not give the required stability, the precise transit was mounted on a 5-ft. section of 6-in. iron pipe, set vertically in concrete at each of the observation stations; it was equipped with a 22-in. telescope with two eye-pieces, one of 30 power and one of 45 power. The plate or horizontal circle has a diameter of 10 in. which, by use of a micrometer attachment, can be read directly to 2″ of arc. It is provided with a precise striding level, the graduations of which have a value of 5″ of arc. The instrument, without the bronze base on which it rests, weighs 41.5 lb., and with the base, 78.5 lb.; the detail of mounting, at the several observation stations, is shown in Fig. 11. About 18 in. of the lower end of the pipe was embedded in concrete, and openings, 3 in. in width and 7 in. in height, were cut in the pipe, just above the surface of the concrete, to permit the use of a plumb-bob in centering the instrument over the "point". Brass tacks, fixed in wooden hubs, were used at first to mark the points, but when the line was finally adjusted, the wooden hubs were replaced with brass plates set in concrete, on which the exact "point" was marked by a punch.

FIG. 9.—LONGITUDINAL SECTION, SHOWING OBSERVATION POINTS ON AXIS OF LONG TUNNEL, CASCADE RANGE.

Projection of Tunnel Axis from Top of Mill Creek Shaft.—The tunnel axis established on the surface of Mill Creek Valley, across the mouth of the shaft, was transferred to the bottom of the shaft in the following manner: The shaft was 8 by 24 ft., inside dimensions, with its long axis parallel to the tunnel tangent. Two piano wires, size No. 20, were suspended down the shaft 622 ft. to sub-grade, to which were attached two 60-lb. plumb-bobs in tubs of water to reduce pendulum motion. These wires were spaced 19 ft. apart.

The suspension of the plumb wires and their alignment at the top of the shaft was accomplished by means of two reels illustrated in Fig. 12. Each of these reels rested on two heavy timbers placed across the shaft collar. The piano wire was coiled in the groove of the drum marked "Hardwood Reel", and a small weight was attached to the free end of the wire and allowed to hang a short distance into the shaft, the wire being made to pass in the V-groove of the rod marked, "Rod 1 in. round by 1 ft. 4 in." Inspection of the diagram will show that the hanging wire can be seen through the frame from either end, so that the frame could be shifted into position by sighting on the wire with a surface transit, set up in proper relation to the tunnel axis.

The final adjustment was made by means of the grooved rod shown in Fig. 12. The nuts through which this rod turns, were bedded firmly in the wood, one of them being stripped of the thread and machined smoothly to act as a bearing. By turning the rod one way or the other, the position of the wire could be shifted very slowly in comparison with the turning of the rod.

When the small weights were lowered to the bottom of the shaft and replaced by the heavy plumb-bobs, these were brought to the required elevation by turning the reels with the cranks. They were held there by means of the pawls engaging the ratchet wheels as shown in Fig. 12. Any additional adjustment of the wires that might be required at the top after the heavy bobs had been attached, could still be easily made by turning the grooved rods.

Two transits were set up at the bottom of the shaft, on opposite sides of the plumb lines in the main tunnel excavation, and each transit was moved into exact line with the two suspended wires. The telescopes were then reversed to throw the line a greater distance from the bottom of the shaft, which was located "off center" from the main tunnel in such manner that 2 ft. of the shaft, along the longitudinal axis, would fall within the main tunnel excavation. The plumbed line was, therefore, an offset line which was corrected to true center by establishing a parallel tangent at the proper offset distance.

Determination of Length of Tunnel Axis

Chaining Legs of Traverse.—Measurements of the tunnel axis involved the determination of "distance" between two given points on the tunnel tangent, outside the portals, by means of an open traverse. A preliminary calculation was made from the two open traverses, which followed the general alignment of the operated line, a system of co-ordinates being used from which to compute "latitude" and "departure".

To determine "distance" in the most precise manner, an open traverse, consisting of four courses, was laid out on the ground and measured, beginning at a point on the tunnel axis produced east of the east portal, and ending at a point in the axis east of the west portal. (See Fig. 13.) One of the courses was laid through the old Cascade Tunnel, and produced eastward for some distance beyond the east portal of the old tunnel.

In laying out the courses through the timber, wide "cuttings" were made in order to secure unobstructed vision between the observation points at either end of each leg of the traverse. These "cuttings" extended for miles through fir, spruce, and hemlock, many of the trees being more than 3 ft. in diameter and 150 ft. in height. The actual measurement of the different "legs" of the traverse was done in the following manner: Substantial stakes were driven in the ground at proper intervals; a brass brad was placed in the top according to transit alignment, and the elevation of the top of the stakes determined by spirit leveling. The actual, or "slope" distance between tack points on the stakes was measured with steel tapes, a precise record being kept of the temperature and the tension on the tape at the time of measurement.

Two tapes were used on the survey; one, 500 ft. long, was used in measuring the old Cascade Tunnel, 2.63 miles in length, through which a part of one of the sides of the traverse was located; the other tape, 300 ft. long, was used entirely in the open.

These tapes were calibrated in Seattle by comparison with U. S. Government Standard, at Government Locks, Lake Washington Canal, at intervals of 100 ft. In addition to the calibration, experiments were conducted to test the standard formulas for lengthening due to tension and for shortening due to sag, with the tape in horizontal and inclined positions. These tests were made for the full length tape, and for 100-ft. fractional parts of it. From the data thus obtained, in order to facilitate the reduction of notes in the office,

The corrections applied were, as follows:

I.—A sag correction graph for the 300-ft. tape supported on level supports at the 0-ft. and 300-ft. marks, with the pull varying, in 10-lb. units, to 60 lb.
II.—A sag correction graph for the 500-ft. tape—conditions similar to those outlined for Correction I.
III.—A correction graph to apply to results taken from Corrections I and II, where tapes are supported by more than two level supports.
IV.—Graphs showing variation in elongation due to variation in pull.
V.—Graphs showing correction for temperature.

VI.—Graphs for corrections required in order to reduce measurements to a datum plane of 2 247 ft. above sea level, this datum being the elevation of the sub-grade at the west portal.

VII.—A graph for applying corrections for sag when the supports are not level, but on a uniform grade.

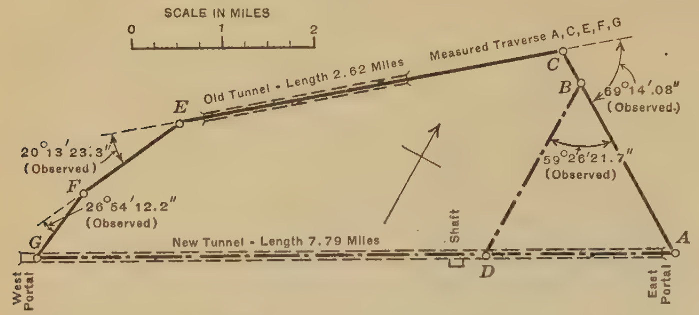

FIG. 13.—PRECISE TRAVERSE, NEW TUNNEL THROUGH THE CASCADE RANGE.

The following is a typical example of computation and applied corrections: The actual field notes for chained distance between Traverse Station No. 159 to No. 160 disclosed that the observed reading, with 30-lb. pull, was 299.900 ft. The tape was supported at five points, uniformly spaced, on a grade with a difference of elevation of outside supports equal to 37.40 ft. The temperature was 79° and the elevation of an end support was 2 904.06 ft. The computation was arranged as shown in Table 3.

True horizontal distance at elevation datum, 2 247 ft., in feet			297.679

Observing Angles.—The precise transits, used in establishing the tunnel axis, were also used to observe the five angles of the precise traverse. The angles were observed in three sets of repetitions by two observers, each repetition consisting of three readings.

An exact record made of each angle reading was entered in the field book. The lengths of the courses were computed from these various field observations, curvature of the earth being disregarded, because the error involved in assuming the surface of the pentagon to be plane instead of spherical, was found to be less than 0.1 ft. for the longest side.

The short distances from Observation Stations *A* and *G*, Fig. 13, to the east and west portals, were measured by the same method used in measuring the sides of the precise traverse.

Triangulation Survey.—As a further check on the distance between portals and the relation of the Mill Creek shaft to either portal, it was decided to make a triangulation survey of the project. The work was carried out in the summer of 1926 by Henry B. Alvord, Assoc. M. Am. Soc. C. E.

The first course of the precise traverse near Berne, which had been measured by methods previously described, was used as the base line for the triangulation system. The results of the first and second measurements of the precise traverse, as compared with the triangulation survey, are shown in Table 4. In determining final measurement, one-third weight was given to the first measurement over the Great Northern traverse and two-thirds weight to the second measurement, the result of the triangulation being used for the purpose of comparison.

TABLE 4.—COMPARISON OF RESULTS

(H. B. Alvord's Results Proportioned to Conform with Observed Length of Base Line, *A C*, in Each Case)

Measurement	Observer	LENGTH OF LINES, IN FEET		
		A D	*C E*	*A N*

	H. B. Alvord	11 402.921	25 064.144	43 751.02
Second	Great Northern Engineers	11 400.358	25 061.449	43 750.22
	H. B. Alvord	11 401.451	25 060.913	43 745.38

Location of Mill Creek Shaft.—The 8 by 24-ft. shaft was "lined in" on the tunnel axis from two intermediate theodolite stations on the east and west slopes of Mill Creek Valley, shown in Fig. 9. The plumbing of the shaft has already been mentioned.

To determine the distance from the east portal to the shaft, the triangle, *A-B-D* (see Fig. 13), was laid out on the ground, the station, *B*, being a point on the base line, *A-C*. Station *D* was a point accurately set on the tunnel axis. The solution of the triangle, *A-B-D*, gave the length of the side, *A-D*, to which was added the measured distance from Station *D* to the mouth of the shaft.

Determination of Grade.—The west slope of the Cascades is everywhere much steeper than the east slope, the rise to the summit of the range being made in a shorter distance. In order to overcome this difference in natural ground slopes, the summit of the tunnel grade was placed at the east portal, which provided a longer distance on the west slope in which to make the climb to the summit, than would have been possible with the summit at some intermediate point between the portals. By following this plan, the same ruling grade was established over the engine district for eastbound and westbound movements.

A uniform grade of 1.565% was laid through the tunnel, descending from east to west. A long vertical curve of 0.10 variation per station connected the tunnel grade tangent with the 1.665% grade, ascending from east to west, on the new approach tracks to Berne.

When the elevation of the top of the shaft had been determined in its proper relation to the east and west portals, the sub-grade of the main tunnel was set 622 ft. below the top of the shaft. A steel tape was used to carry the measurement down the vertical side walls of the shaft.

Table 5 shows the comparison between the old and new line, between Berne and Scenic.

TABLE 5.—COMPARISONS BETWEEN THE OLD AND NEW LINES BETWEEN BERNE AND SCENIC

Items	Old line	New line	Favorable to new line

GENERAL PLAN OF ATTACK

The final plan for the construction of the Simplon Tunnel in the Swiss Alps was devised by the Jura-Simplon Railway Company in 1893, and was submitted, by an arrangement with the Swiss and Italian Governments, to a commission of experts, made up of Guiseppe Columbo, an engineer of Milan, Italy; Francis Fox, of London, England; and C. J. Wagner, of Vienna, Austria, State Inspector of Railways, formerly one of the engineers of the Arlberg Tunnel.

The plan provided for the driving of a secondary gallery, or pioneer tunnel, parallel to the main tunnel and 55.75 ft. from it. This pioneer tunnel was to be used to drain off underground water and to convey fresh air and cold water to the working faces. The plan had special merit in that it made it possible to enlarge the auxiliary gallery to a full-sized tunnel for double-track operation, whenever traffic conditions warranted such expenditure.

In formulating the plan for driving the New Cascade Tunnel, considerable study was given to the method of construction used on the Simplon Tunnel, and, as a result, it was decided to drive a pioneer tunnel between Mill Creek and the west portal.

The Mill Creek shaft divided the tunnel into two segments, the easterly portion being 2.41 miles in length, and the westerly portion, 5.38 miles. A study of time schedules showed that the section of tunnel between the east portal and Mill Creek could be completed within three years by following the center-heading method, without the aid of a pioneer tunnel, but that the section of tunnel between Mill Creek and the west portal would require the use of an auxiliary haulage-way.

Accordingly, a pioneer tunnel was laid out between the shaft and the west portal, 66 ft. to the south of, and parallel with, the center line of the main tunnel, corresponding to the 55.75-ft. offset distance used in the Simplon Tunnel. (See Fig. 14.) It was considered that this interval provided sufficient distance away from the main tunnel to avoid disturbance to the rock formation without being too far away to complicate the construction of cross-cuts and the movement of spoil trains and construction supplies, back and forth between the pioneer and the main tunnel. In the event of future double track, the pioneer tunnel could be enlarged for second track, as was done in the Simplon Tunnel, or it could be used as a haulage-way from which to attack the new tunnel at intermediate points, as might be required. Likewise, the pioneer tunnel made permanent provision for taking care of the drainage from the main tunnel.

FIG. 14.—PLAN OF MAIN TUNNEL, PIONEER TUNNEL, AND CROSS-CUTS.

CONTROLLING FEATURES OF PROJECT

The controlling features of the project, which made it necessary to attack the work simultaneously at several intermediate points between portals, were as follows:

(1) Length of tunnel, 7.79 miles.
(2) Size of tunnel, single-track (see Fig. 15).
(3) Grade, 1.565%, descending east to west.
(4) Tunnel to be lined with concrete throughout.
(5) Possibility of encountering heavy volume of water.
(6) Time for completion, 3 years.

In formulating a plan of attack, every consideration had to be given the water problem, with the possibility of encountering water in such quantities that drifting operations, down grade, might be brought to a standstill.

The tunnel grade descended from east to west, and at the time of starting construction it was not known how successful the tunneling operations would be, if driven down grade. Judging from the rainfall in the winter months throughout the Cascade Range, with its numerous mountain streams and springs, it was reasonable to expect water-bearing rock formation in all primary penetration. These uncertain factors, together with the speed requirements of the time schedule, were responsible for the decision reached to sink the Mill Creek shaft and drive a pioneer tunnel west of the shaft. The shaft opened up several new points of attack, and in case water in any considerable quantity was met between the east portal and the shaft, drifting operations could be continued up grade from the bottom of the shaft, the water encountered being drained by gravity into large sumps, and then lifted to the top of the shaft by electrically driven force pumps. Similarly, the pioneer tunnel, in advancing eastward (up grade) from the west portal, made it possible to drive the several cross-cuts to the main tunnel up grade, so that water from the enlargement operations would have gravity flow to the west portal.

Tye River Incline.—The surface indications at the west portal were of such a character that it was practically certain that soft ground would be encountered for a distance of about 1 000 ft. To avoid the delay which would result from excavating through this heavy ground, it was decided to drive a 30° incline adit, 251 ft. long, from the Tye River Valley to the pioneer tunnel, intersecting the pioneer center line and grade at a point 2 279 ft. from the west portal. Subsequent developments justified this move, as the material encountered in the pioneer tunnel, west of the adit, was of such a character that the advanced pioneer drifting crews, served from the Tye River incline, had penetrated to a point 5 703 ft. from the west portal by the time the west portal crews broke through into the advanced drift.

UNDERGROUND INSTRUMENTAL CONTROL

To obtain the location of the tunnel portals for starting the underground operations, the axis of the tunnel, as determined by the line over the mountains, was transferred to a point near each portal by a direction theodolite (see Fig. 9).

In the case of the east portal, the line was thrown down from the theodolite set up on the mountain east of the east portal (near Berne), using the monument east of Mill Creek as a foresight. A transit was then set up over the "point" near the east portal, and the monument east of Berne was used as a back-sight to produce the line into the tunnel. At the west portal, corresponding operations were carried out and, in addition, a base line was established to control the pioneer tunnel. An offset line, 66 ft. parallel to the main tunnel axis, was laid out on the south side of the tunnel tangent, and this base line was used to project the line into the pioneer tunnel. In the case of the underground workings near the Mill Creek shaft, the 19-ft. base line, plumbed down from the top of the shaft, was used to carry the line forward toward the east and west portals.

All the advanced workings in the main tunnel between the west portal and the Mill Creek shaft, were controlled from the pioneer tunnel, both as to line and levels. As soon as the underground operations had advanced any considerable distance, more precise methods of establishing line and grade were used. In following up the main enlargement from the east and the west portals, the large direction theodolite, mounted on a 6-in. iron pipe support, was used to give the final line. On account of the heavy smoke, long sights were, as a rule, impossible. Leveling was done with levels having 24-in. telescopes, 4-ft. Philadelphia rods being used, where required.

In driving the 10 by 10-ft. center heading between the east portal and the Mill Creek shaft, under the instrumental controls previously described, the drifting crews met on March 4, 1927, at a point 3 200 ft. east of the shaft, 9 543 ft. west of the east portal. The error of closure was 0.23 ft. for "line", 0.2 ft. for "grade", and 1.9 ft. for "distance".

In driving the 8 by 9-ft. pioneer tunnel eastward from the west portal, and westward from the shaft, the two crews came together on May 1, 1928, at a point 17 775 ft. from the west portal. The error of closure was 0.64 ft. for "line", 0.78 ft. for "grade", and 1.0 ft. for "distance". (See Fig. 14.) This junction of the two control lines in the pioneer tunnel, well in advance of enlargement operations in the main tunnel, provided a ready means of checking back over the offset lines, connecting the pioneer with the main tunnel, so that a perfect tangent was established in the main tunnel, before the concrete lining was placed.

General Standards of Construction

Tunnel Section.—The internal width of the tunnel, between the concrete side walls, was determined from Great Northern tunnel standards which provided for a 16 ft. 0 in. width on tangent track. The internal vertical clearance did not follow the Great Northern standard of 22 ft. from top of rail to center of roof arch.

The electrification of the tunnel had been decided upon in the preliminary studies and in designing the tunnel section, a three-centered roof arch was provided. An 11 000-volt contact system was specified for present installation but, in planning the electrification, it had been decided to provide space for insulation against a future 22 000-volt trolley line and, in order to avoid the necessity of increasing the height of the roof arch, to provide for the longer insulators which would be required for the higher voltage, special plans were made for attaching the overhead trolley system to the roof of the tunnel, which reduced the distance between the trolley and the tunnel roof. Circular domes, 5 ft. 0 in. in diameter and 1 ft. 2 in. deep, were provided at the center of the concrete roof arch, at 75 ft. 0 in. intervals, from which the trolley insulators were suspended by means of a bronze insert, set accurately in place during the process of pouring the concrete lining.

The use of these domes and the three-centered roof arch was economical in that for a given height of trolley wire, as shown by Fig. 15, it resulted in reduction in quantity of rock excavation and diminished height of concrete side walls throughout the length of the tunnel.

The external horizontal and vertical axes of the tunnel section are variable according to the nature of the rock and the amount of excavation necessary to provide proper thickness of concrete lining. (See Fig. 15.) As a general rule, the following vertical and horizontal dimensions were used in the process of enlarging to full tunnel section:

Hard rock, requiring no timbering, 18 ft. 0 in. width by 25 ft. 0 in. above tunnel sub-grade.

Soft rock, requiring no timbering, 20 ft. 0 in. width by 25 ft. 6 in. above tunnel sub-grade.

Earth or rock, requiring timber lining, 22 ft. 0 in. width by 27 ft. 6 in. above tunnel sub-grade.

In placing the 12 by 12-in. timber lining, the timber sets were spaced, longitudinally, according to the character of the earth or rock.

Track.—Track is laid with Great Northern section, 110-lb. rail, and 7½ by 10-in. steel tie-plates, weighing 13.05 lb. each; 3 200 creosoted ties, 7 by 9 in. by 8 ft. long, are used per mile of track; 21 in. of washed gravel ballast was placed under the ties after the tunnel floor was built and leveled off to sub-grade with broken rock.

Drainage System.—The quantity of water encountered in underground operations differed greatly throughout the tunnel, and the permanent drainage system was designed to meet these varying conditions so as to provide ample capacity without unnecessary expense.

The east half of the tunnel was driven through comparatively dry formation, so that from the east portal westward for 3.85 miles, water, entering the tunnel from 4-in. weep-holes through the concrete lining along both sides of track, was carried in side ditches. In this distance, there was not a sufficient quantity of water to cause any trouble. At a point 3.85 miles from the east portal the accumulation of water was turned into the pioneer tunnel by means of a 12-in. pipe, embedded in the south wall of the concrete tunnel lining.

From this easterly cross-drain westerly, for a distance of 2.38 miles, the tunnel passed through a heavy, water-bearing formation, which required that cross-drains to the pioneer tunnel be constructed about every 1 500 ft. The pioneer tunnel, therefore, became the permanent artery of the drainage system, into which all water entering the main tunnel between the east portal and the most westerly cross-drain, a distance of 6.23 miles, was diverted. No cross-drains from the main tunnel to the pioneer tunnel were found necessary, from a point 1.56 miles east of the west portal to the west portal, because no heavy, water-bearing formation was encountered in this westerly section.

The bottom of the Mill Creek shaft was filled with concrete to a point 10 ft. above the top of the concrete tunnel arch. A 6-in. pipe was placed in the concrete, discharging into the south side ditch of the main tunnel. The Mill Creek shaft was then completely back-filled with the broken rock, removed in the process of sinking the shaft.

FIG. 16.—PLAN SHOWING METHOD OF DIVERTING WATER FROM SIDE DITCHES OF MAIN TUNNEL TO PIONEER TUNNEL.

Fig. 16 shows the typical plan used to divert water from the main to the pioneer tunnel. The size of the cross-drain pipe was dependent upon the flow of water, 20-in. pipe being used in most cases. Thirteen permanent cross-drains were built and these continue in service. At present, there are about 5 000 gal. per min. flowing out of the pioneer tunnel at the west portal, and steps are now being taken to maintain the pioneer tunnel, west of the first cross-drain (3.85 miles from east portal), by placing concrete lining in such sections as require it. Thus, there will be 3.94 miles of the pioneer tunnel in permanent use as a water tunnel.

Refuge and Transformer Bays.—Refuge bays, 8 by 8 ft., were placed in the south tunnel wall at 1 200-ft. intervals, within 1 mile of the east and the west tunnel portals and at 2 400-ft. intervals in the middle section of the tunnel. Transformer bays were placed in the north tunnel wall at 2 400-ft. intervals.

Three lines of 4-in. sleeve-joint fiber conduit were placed in the north tunnel wall. One of these conduits was used to carry the 13 200-volt lighting and signal primary; one was used for the tunnel telephone circuit wiring and signal wiring for the operation of the track circuits; and one conduit was reserved for future use. One 3-in. galvanized-iron conduit was placed in the south wall to carry telegraph and telephone cables.

Automatic Signal System.—The automatic signal system through the tunnel provides positive blocking in both directions for following and opposing train movements. It consists of an eastward starting signal at the east passing-track switch at Scenic and a westward starting signal at the west passing-track switch at Berne, together with five double-signal locations within the tunnel.

These signals are of the color-light type and, on account of the positive block, are of two colors only, with the exception of the "distant to entering" signals at Scenic and Berne, where the third indication is given.

The locations within the tunnel are spaced 9 600 ft. apart and are located so that one pair is at the center, one pair 2 miles in from either end, and one pair approximately 1 400 ft. from each portal. All the locations are at the transformer bays. Track circuit sections extend from location to location 9 600 ft. in length and are of the center-fed type, making insulated joints and reactance bonds necessary only at signal locations.

Power is supplied at a frequency of 60 cycles, to make it distinctive from the 25-cycle propulsion power. It is possible, therefore, to separate the 60-cycle signaling current on the rails from the 25-cycle return propulsion current by use of centrifugal type track relays, which respond only to the higher frequency.

The 13 200-volt signal transmission line is tapped in the transformer bay every 2 400 ft. for lighting and every 4 800 ft. for signaling connections. This is a lead-covered cable consisting of two No. 4 soft-drawn conductors. It is stepped down in the transformer bays to 110 volts for signaling and 220 volts for lighting. The cable is entirely sectionalized at the center bay and at the 2-mile bays. The track reactor bonds, with a capacity of 500 amperes per rail, which make the track continuous for propulsion current, but permit it to be cut into insulated sections for signaling current, are located in the transformer bays at the signal locations. The control circuits are carried in rubber-covered wire through a fiber conduit in the tunnel wall and alternating-current line relays are used throughout.

The light signals are bolted directly to the tunnel wall so that their lowest point is at the level of the top of the rail, without encroaching on the side clearance. They are 8-volt 10-watt lamps, lighting directly from the alternating current, with a second or emergency light arranged to cut into the circuit automatically if the bulb in the green unit should burn out. All lights are operated on the approach lighting system. The two-color units show red for "Stop" and green for "Proceed", while the three-color units show red for "Stop", yellow for "Caution", and green for "Proceed".

Telegraph and Telephone Circuits Through Tunnel.—The railway and commercial telegraph and telephone circuits were carried through cable in a 3-in. galvanized-iron conduit in the south tunnel wall, below the floor level of the refuge bays. The iron conduit was used in order to get the benefit of its magnetic shielding effect, the usual lead sheath of the cable having no such magnetic qualities, although, of course, it does possess electrostatic shielding properties. The conduit run was broken every 600 ft. by cast-iron pull-boxes of special design, the cable being pulled in in 600-ft. lengths, and spliced at each box. The electrical continuity of the conduit was preserved past the box joints by spot-welded bond wires carried around each box. The entire conduit system was grounded, to provide effectual drainage of stray high-tension current.

The cable used was of American Railway Association, Telegraph and Telephone Section, Type H, 14 pairs, with the added dielectric strength of the double-paper insulation, providing for 2 000-volts breakdown between conductors, and 3 500 volts between conductor and sheath. All conductors were both paired and quadded, and all are 13 B. & S. gauge. Three quads, or six pairs of conductors, were equipped with loading coils, for telephone service. Load coils are located every 6 000 ft., or at every tenth pull-box, where an additional niche was cast in the tunnel lining of sufficient size to accommodate the coil on the top of the pull-box. As the load coils are enclosed in iron casings, no further mechanical or electrical protection was required for them. The loading coils reduce the impedance of the cable conductors to approximately that of open wire. The cable was extended at the portals sufficiently to run out even 6 000-ft. sections, and was terminated in fireproof tile and concrete cable houses, where it is protected against high voltages from outside the tunnel by two sets of standard carbon block protectors, with 14-ampere fuses, and with a set of gas protectors between the two sets of carbon protectors.

Communication locally in the tunnel is carried on through a separate rubber-insulated lead sheath cable, carried in the conduit with the signal secondaries in the north wall. Telephones of the weather-proof, iron-box, mine type are provided in each refuge bay, and the circuit is continued to the depot office near each portal, where necessary switching apparatus is provided to connect such tunnel circuit to the dispatcher's or other telephone circuits, as may be required. Extra conductors are also provided in this cable to take care of the dispatcher's telephone and to provide necessary test conductors, should the main cable be damaged beyond immediate repair. Each telephone on the tunnel circuit is operated through an insulating transformer, to insure operation under adverse inductive conditions without danger to the user.

Tunnel Lighting.—Lighting recesses were placed at 112½-ft. intervals, "staggered", throughout the length of the tunnel. A plan was developed to utilize the 3/0 conductor No. 2 cable, which was used to furnish power for tunnel construction, as a means of providing for flood lighting at any point throughout the tunnel. These cables are attached to the side walls of the tunnel in such a manner that any part of the track can be lighted for the benefit of track gangs.

Trolley.—The 11 000-volt contact system throughout the tunnel is of simple catenary construction, consisting of a 350 000-cir. mils, stranded, copper messenger from which is suspended, by flexible loop hangers, a single 4/0 hard-drawn copper contact wire. The messenger is supported at 75-ft. intervals by a three-unit suspension type insulator and the entire contact system is sectionalized with an air gap and anchored at spacings of approximately 1 mile. Suspension type insulators were used throughout, both for messenger suspension and for strain insulators at the air gaps, with a voltage rating of 60 000.

Line and Grade Improvements, East Slope of Cascades

Coincident with the construction of the New Cascade Tunnel, and the electrification of the main line, a comprehensive program of grade and curve reduction and elimination of snowsheds was carried out on the east slope of the Cascade Range between Peshastin (a station 19 miles west of Wenatchee) and Berne, near the east portal of the new tunnel. (See Fig. 2.)

The Chumstick Line.—The important part of this line revision was the construction of the new Chumstick Line from Peshastin to Winton, 16.92 miles, at a cost of nearly $5 000 000. The building of the Chumstick Line, so-called from the name of the creek valley which it follows for 7 miles, had been under consideration for a number of years prior to the construction of the New Cascade Tunnel.

In 1921, surveys were made for various routes *via* the Chumstick Valley, to avoid the Tumwater Canyon of the Wenatchee River. Most of these investigations contemplated turning off the old line near the Town of Leavenworth. The line that was constructed was a more radical improvement, in that better standards were used, with maximum curvatures of 3°, and a maximum grade of 1.6 per cent. In order to adhere to these standards, it was necessary to construct a spur line, 8 860 ft. long, to Leavenworth, to serve that community with carload freight.

The old main line followed the water grade of the Wenatchee River from its mouth to a point about 2 miles east of Winton, as shown in Fig. 2. The fall of the Wenatchee River between Leavenworth and its confluence with the Columbia River, is only 23 ft. per mile, but above Leavenworth, as far as Chiwaukum, the river passed through the Tumwater Canyon in a succession of rapids, where the rate of fall, in certain sections, is 100 ft. per mile. The old line was benched in on the north bank through this canyon, which required the use of 2.2% grades. For some distance through the canyon, the old track was protected against snow and rock slides from the upper slope by timber sheds, a large percentage of which required renewal in 1928 and 1929. Of these sheds, 8 401 lin. ft. were already in place, and to protect the line adequately through the Tumwater Canyon, it was considered necessary to build approximately 4 000 ft. of new sheds. The large snowshed program confronting the Railroad Company in the near future was a deciding factor in favor of the new route, but there were other advantages to be gained by the construction of the Chumstick Line, which may be briefly listed as in Table 6.

TABLE 6.—ADVANTAGES OF CHUMSTICK LINE COMPARED WITH OLD LINE, PESHASTIN TO WINTON (16.92 MILES)

Item	Old line	New line	Saving

General Route.—Chumstick Line.—The new Chumstick Line turns off from the old line at Peshastin, and follows comparatively level bench lands until the Chumstick Valley is reached. The line then turns up this valley for about 7 miles, with very good general alignment; it penetrates a ridge, separating the Upper Chumstick Valley from the Wenatchee River Valley, by a tunnel 2 601 ft. long, and crosses the Wenatchee River ½ mile from the west portal of the tunnel on a 360-ft. steel bridge, at a point about 5 miles above the old line crossing, near Chiwaukum. For the next 2 miles, the line is laid along the slopes above the Wenatchee River, and follows Dead Horse Canyon for 1 mile, to a tunnel, 4 059 ft. long, through the ridge to Winton, where it connects with the old grade.

The maximum grade on this line is 1.6%, against westbound traffic, and is compensated for curvature. The first section of the 1.6% grade is 3 miles long, and the second section, 3½ miles long, and, except for these two stretches, the maximum grade is 1.5%, compensated.

Minor Line Revisions.—In addition to the new Chumstick Line, numerous short sections of the old line between Winton and Berne, a distance of 14 miles, were improved in alignment and grade. From Winton westward to Nason Creek (3 miles), a radical line change was made at a cost of about $500 000, which crossed and recrossed the old line, eliminating considerable curvature and improving the grade. There was a false summit on the old line at Winton which was approached by 2.2% grades westbound and 1% grades eastbound. This summit was lowered, and the sag to the westward was raised so as to provide a 1% westbound and a 0.6% eastbound grade.

Several other small line changes, in which a number of sharp curves were eliminated or reduced, were made on the east slope of the Cascades, by the distribution of 254 109 cu. yd. of tunnel spoil in a distance of 7 miles.

PART III.—CONSTRUCTION PLANS AND METHODS

BY J. C. BAXTER,[4] M. AM. SOC. C. E.

As stated in Part I, the snowshed problem on the west slope of the Cascade Range early brought under consideration, by the Chief Engineers of the Railway Company, routes avoiding the snowslide area. All these routes embodied long tunnels through the Cascade Range and in the later examination of these various projects, studies were made by the contractor (A. Guthrie & Co., Inc.), of the probable time required for driving the tunnels.

These studies were made with the primary thought of rapid progress:

First.—To save interest during construction.

Second.—Because additional savings could be made during the last year and possibly during the last two years of the construction period by not spending any money on replacement of snowsheds.

Before proceeding with a detailed time study of any of the various tunnel projects, an examination was made of the methods that had been used for driving railway and mine tunnels, and of the probable drainage requirements of a long tunnel through the Cascade Range. From this examination the following statements were developed:

(*a*) The highest rate of progress in a long railway tunnel, as represented by total length divided by total time, had been made in the Simplon Tunnel, completed in 1906, and driven from an outside working gallery, or pioneer drift.

(*b*) The next highest rate of progress had been made in the Rogers Pass or Connaught Tunnel on the Canadian Pacific Railway in British Columbia, which was completed in 1916 and was probably the first example in the Western Hemisphere of the use of the Simplon outside gallery, or pioneer drift.

(*c*) The lowest cost per cubic yard for heading excavation obtained by the contractor had been made in a double-track tunnel through shale in the Rocky Mountains on the Great Northern Railway, where working galleries on each side of the tunnel at the wall-plate elevation had been driven its entire length before proceeding with the heading excavation, which was then carried out from cross-cuts connecting the two working galleries, or pioneer drifts.

(*d*) The advantages of an outside working gallery could be obtained, under certain conditions, by the use of a shaft, as exemplified by the Ozark Tunnel, in Illinois, on the Illinois Central Railway.

(*e*) Where, as in the case of the Simplon Tunnel, the pioneer drift was afterward enlarged to a second railway tunnel, a pronounced saving in cost accrued, in addition to the increases in speed, and it was possible that a long tunnel through the Cascade Range might eventually require double track, or at least the construction of a passing track at its mid-length.

From a study of mining methods it appeared that most low-cost coal mining operations were conducted from working galleries or drifts. A study of the probable drainage requirements indicated that:

---

[4] Contr. and Engr. (Carey, Baxter & Kennedy), New York, N. Y., formerly Vice-Pres., A. Guthrie & Co., Inc.

(1) Practically all long tunnels driven in the past had developed large flows of water.
(2) The rocks of the Cascade Range, on account of the heavy annual precipitation, might be expected to carry water in large quantities.
(3) An outside working gallery, or pioneer drift, would facilitate the handling of water during construction, and provide an auxiliary drainage gallery into which any permanent flows of water could be diverted.

In consideration of the foregoing it was decided to assume a pioneer drift, or vertical shaft, where either were applicable, in making studies of the probable time that would be required to drive any of the projected tunnels.

These studies indicated that the tunnel on the route finally selected could be driven in three years. To arrive at this time the following plan had been outlined:

(*a*) The line of the tunnel was crossed at a point about one-third the distance from the east end by the Valley of Mill Creek, the tunnel grade at this crossing being only 622 ft. below the floor of the valley. A shaft at this point would cut the tunnel into two portions: An eastern section, 2.41 miles long, and a western section, 5.38 miles long; thereby reducing the continuous length of tunnel to be attacked to the length of the western section; that is, 5.38 miles.

(*b*) The Western section if attacked from both ends (through the west portal and the Mill Creek shaft), could be completed in three years, using a pioneer drift and center heading and removing all the enlargement muck from one face if the ground was favorable to enlargement from a center heading. If the ground was not favorable to such an operation, then the section could be completed in three years by as many secondary enlargement operations served through the pioneer drift as were necessary.

(*c*) The eastern section was obviously one that could be completed in three years in many different ways. However, it was almost certain the tunnel would require concrete lining throughout. There was no suitable aggregate for concrete near the Mill Creek shaft, which was two miles from the operated line of the railroad. The plan on this section was to speed it up by driving a center heading from both the east portal and the Mill Creek shaft, enlarging this section entirely from the east portal while securing access to the center heading from the Mill Creek shaft instead of a pioneer drift. In this way it would be possible to complete the eastern section early enough so that aggregate for the concrete lining of that section and of the section driven west from the Mill Creek shaft, could be delivered by rail at the east portal, which was practically on the line of the existing railroad.

(*d*) The ground from *A* to *B*, Fig. 17, consisted of the remains of an old slide, and it was certain that the penetration of this distance would be very slow. Therefore, an inclined shaft was proposed at *B* in the Valley of the Tye River, in order that the pioneer drift might be advanced continuously during the period that would be required to drive through from the west portal to *B*.

A time-distance chart based on this general plan is shown in Fig. 18, on which has been superimposed the actual progress in the various operations. After decision to construct the tunnel had been reached, this general plan was adopted and the tunnel successfully completed. However, this success was due to the flexibility of the general plan adopted, in that it permitted wide variations of procedure where necessary to meet changing ground and water conditions. Sudden and great changes in ground and water conditions have been typical of all long tunnel operations, and the Cascade Tunnel ran true to type, but, as mentioned, the basic plan of operation lent itself readily to meeting these contingencies.

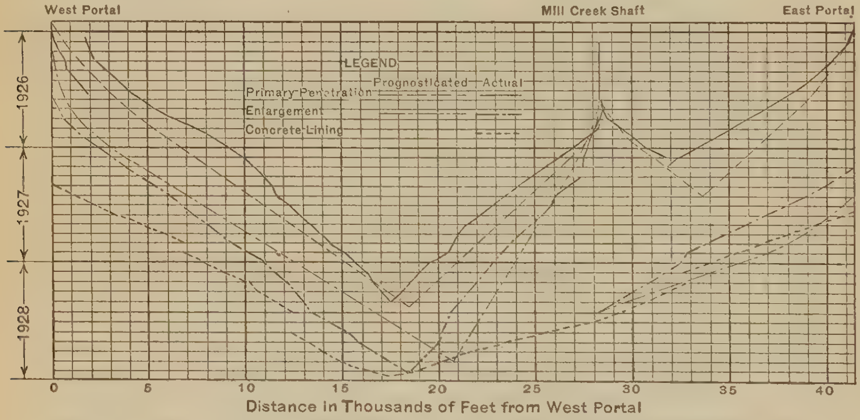

FIG. 18.—TIME-DISTANCE PROGRESS CHART, SHOWING ACTUAL COMPARED WITH PROGNOSTICATED PROGRESS, CASCADE TUNNEL.

To meet the various ground conditions encountered, seven general methods of attack were utilized, with combinations of some of them for short distances. These methods of attack and the conditions governing their use, were:

1.—Center heading, followed by enlargement (shown in Fig. 19). This was the basic method in the Cascade Tunnel plans. However, it only produces the best results where the ground is such that a full section of the tunnel will stand without timbering.

2.—Center heading, followed by top heading and bench (shown in Fig. 20). This method was used in ground where, after driving the center heading, it became apparent that the full tunnel section would not stand without timbering.

3.—Top heading and bench (shown in Fig. 21). This method is the usual so-called "American Method" and was used in ground which, from indications in the pioneer drift, obviously would not stand without timbering.

4.—Wall-plate drifts, followed by top heading and bench (shown in Fig. 22). This is a modification of the method described under Method 3 and was used in ground too soft to stand for a full top heading.

FIG. 20.—METHOD OF ENLARGING TO FULL TUNNEL FROM CENTER HEADING FOLLOWED BY TOP HEADING AND BENCH.

5.—Center top heading and wall-plate drifts simultaneously, followed by full top heading and bench (shown in Fig. 23). This is the so-called "Crown Bar Method" and was used for penetrating the old slide material at the west end of the Cascade Tunnel.

6.—Bottom heading followed by raises and top heading, the wings being removed by shovel (shown in Fig. 24). This is a method very similar to that under which the original No. 1 Tunnel of the Simplon was driven, and was made use of in the Cascade Tunnel in order to expedite completion by introducing hand-tunneling operations through several of the cross-cuts after the pioneer was holed through.

FIG. 24.—DIAGRAM SHOWING METHOD OF ENLARGING TO FULL TUNNEL FROM BOTTOM CENTER HEADING BY TOP HEADING AND RAISES.

7.—Full tunnel face (shown in Fig. 25). This is a method seldom used in tunneling, but was adopted in the Cascade Tunnel in order to expedite completion by providing additional mechanical loading places, reached through cross-cuts from the pioneer drift in advance of the main enlargement operation. The procedure is to shoot 1*A* first and 1*B* immediately thereafter. The independent round is then drilled and shot as soon as ready.

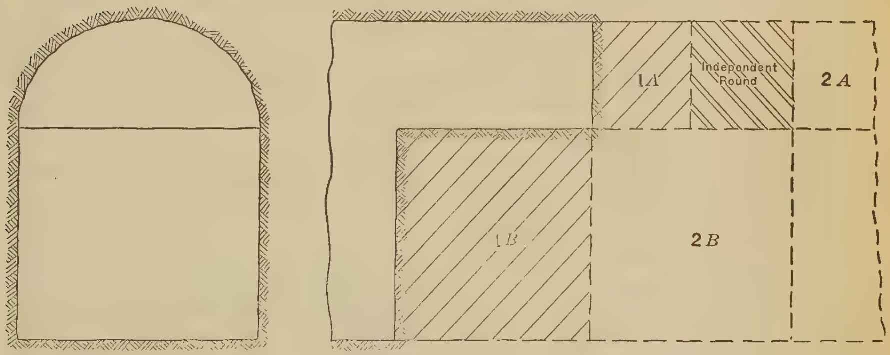

FIG. 25.—DIAGRAM SHOWING METHOD OF DRIVING FULL TUNNEL FACE.

DRAINAGE

When laying out the plan of operations the problem of water to be encountered was given careful consideration along the following lines:

(*A*) The tunnel was located through the Cascade Range in an area of high precipitation, cut by many sturdy mountain streams and containing many springs, several of which in the near vicinity were warm. It was, therefore, almost certain that water in large but unknown quantities would be encountered.

(*B*) The tunnel grade was all in one direction, down hill from the east portal.

(*C*) Water in any quantity would slow up the operation, but in large quantities (from 3 000 to 5 000 gal. per min.) would probably cause the abandonment of an operation being carried out down hill.

(*D*) The continuity of the down-hill operations from the east portal and from the Mill Creek shaft was uncertain.

(*E*) If abandonment of the down-hill operations was forced by the inflow of water, the tunnel could probably be completed in three years and six months (as indicated by the time-distance chart, Fig. 26).

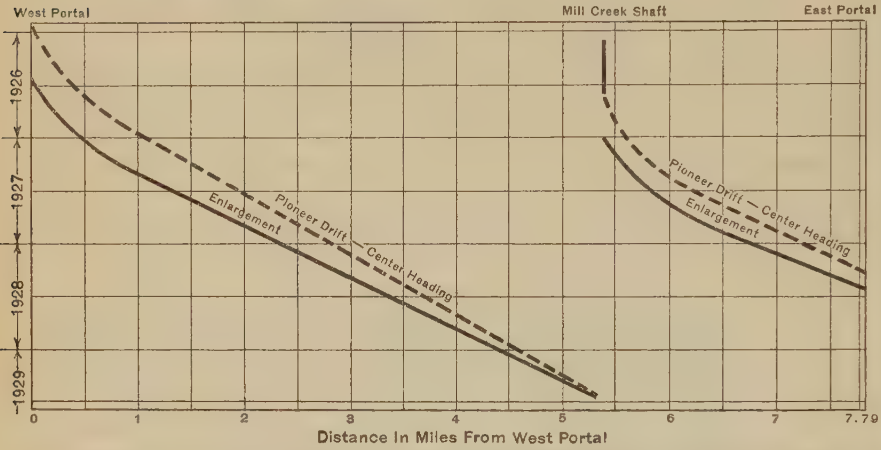

FIG. 26.—TIME-DISTANCE CHART SHOWING PROBABLE PROGRESS BASED ON UPGRADE OPERATION FROM WEST PORTAL AND MILL CREEK SHAFT.

Actually no water of any consequence was encountered between the east portal and the Mill Creek shaft, and the center heading between these points was holed 2.93 months ahead of schedule.

The Mill Creek shaft was originally equipped with pumps having a capacity of 2 200 gal. per min., with the idea that before this capacity was reached additional pumps would be installed.

The operations west from Mill Creek developed a maximum of 2 800 gal. per min. and this was successfully handled without flooding the entire work, although on several occasions it became necessary to flood the main tunnel in order to protect the pioneer. The maximum flow from a single point of discharge in the operations west of Mill Creek was 800 gal. per min. This flow, added to the other water then being handled, threatened to flood the work, but was shut off by a concrete bulkhead and developed against the bulkhead a pressure of 100 lb. per sq. in. The bulkhead was fitted with an outlet pipe and valve and the water behind this bulkhead was gradually drained to the pumps at a rate they could handle. A curve showing the total water discharge from the Mill Creek shaft is given in Fig. 27.

Fortunately, the worst water conditions were encountered in the operations being driven up hill from the west portal where the water could flow out by gravity and where a maximum discharge of 10 300 gal. per min. was developed. Practically all the water encountered was ground-water filling fissures in the rock. These fissures were of all sizes—from hair-cracks to 6 or 8 in. across. All these fissures acted in the same manner: A maximum flow when first encountered; a radical decrease in the flow in the next few days (sometimes hours), with a gradual decrease over weeks and months, at times drying up entirely.

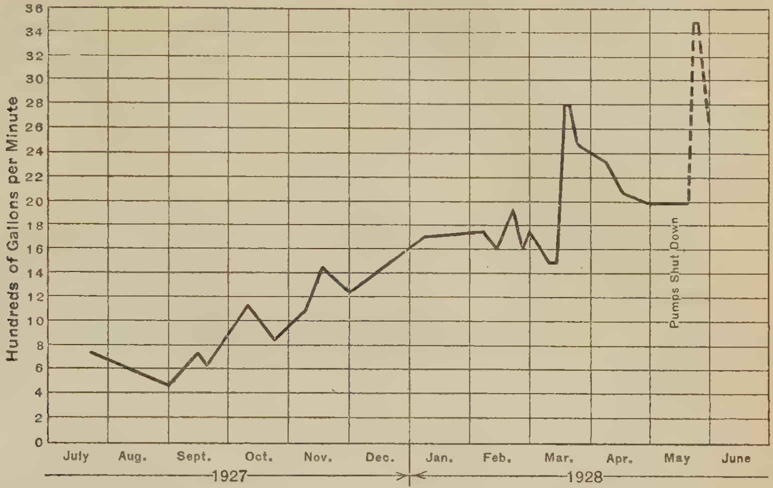

FIG. 27.—CHART SHOWING QUANTITY OF WATER IN GALLONS PER MINUTE PUMPED AT MILL CREEK SHAFT. BROKEN LINE INDICATES FLOW TO WEST PORTAL.

Very high pressures were occasionally encountered in drilling, but were never measured accurately; for instance, a 12-ft. drill steel, 1¼ in. in diameter, when released from the drill, was forced out of the hole by the water pressure, the steel passing back over the drill carriage and injuring a nipper who was about 15 ft. back from the face.

The maximum flow from a single point of discharge in the west portal operations was 5 000 gal. per min., but this dropped rapidly within 24 hours. A curve showing the total water discharge from the west portal operations is given in Fig. 28.

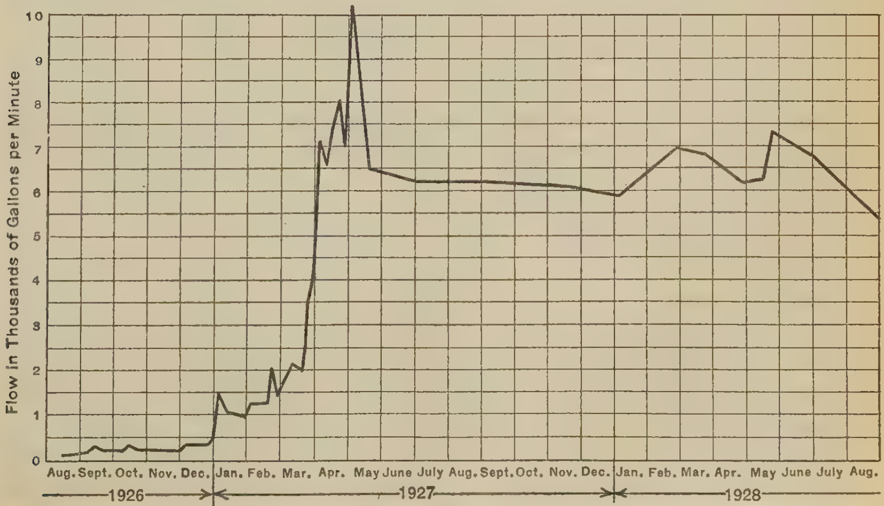

FIG. 28.—CHART SHOWING FLOW OF WATER IN GALLONS PER MINUTE AS MEASURED AT PORTAL OF SCENIC PIONEER TUNNEL.

The original plan of the pioneer tunnel is shown in Fig. 29. This was wrong in two respects:

1.—The drainage ditch shown at the side was not of sufficient capacity to carry the quantity of water encountered and was difficult to maintain. Fig. 30 shows the water conditions in the pioneer at their worst and Fig. 31 shows one of the larger flows in this same operation. For a tunnel expected to take care of large quantities of water, a plan shown in Fig. 32 has been developed and is now (1931) in use in driving the Mahr Drainage Tunnel, 6 miles long, for Cerro de Pasco, in Peru.

2.—The pioneer is shown in Fig. 29 as level with the center heading. This location is simple and to be preferred when considered with relation to driving the center heading, but does not lend itself to the future permanent drainage of the main tunnel. In order to accomplish this latter purpose, the grade of the pioneer should be level with the grade of the main tunnel. In the Cascade Tunnel the grade of the pioneer was dropped and 1.32 miles of it are level with the main tunnel grade.

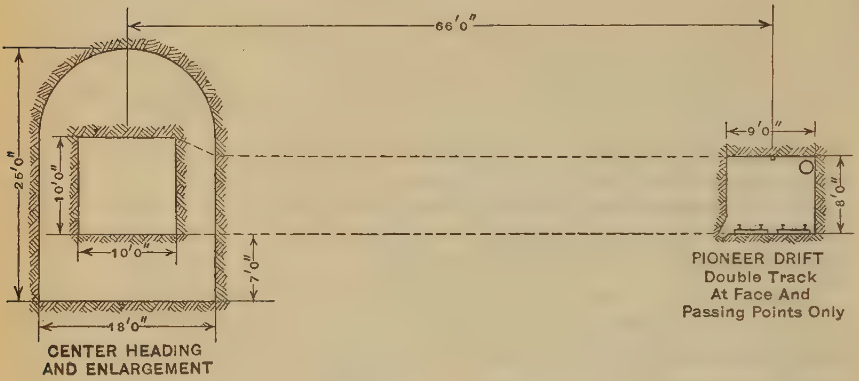

Fig. 29.—Diagram Showing Cross-Section of Pioneer Tunnel and Relation to Main Tunnel as Originally Planned.

Ventilation

After deciding upon a general plan of operation for driving a long tunnel, the next subject to be considered is the tunnel plant, the most important elements of which are the ventilating units, which, in turn, are dependent to a large degree upon the plan of operations.

In the case of other tunnels driven before this one, experience had shown that about 4 000 cu. ft. per min. of fresh air was necessary at each working place and that about 20 000 cu. ft. per min. was the minimum that would keep the full tunnel section reasonably clear. These values were used in preparing the ventilation layout and proved to be ample. The general opinion of the men, some of whom had worked in nearly every recent underground operation in the United States, was that the Cascade Tunnel was one of the best ventilated.

The most difficult ventilation problem occurred in the operations carried on from the west portal, which were planned to go 3.5 miles underground and actually were carried forward 3.36 miles before the hole through.

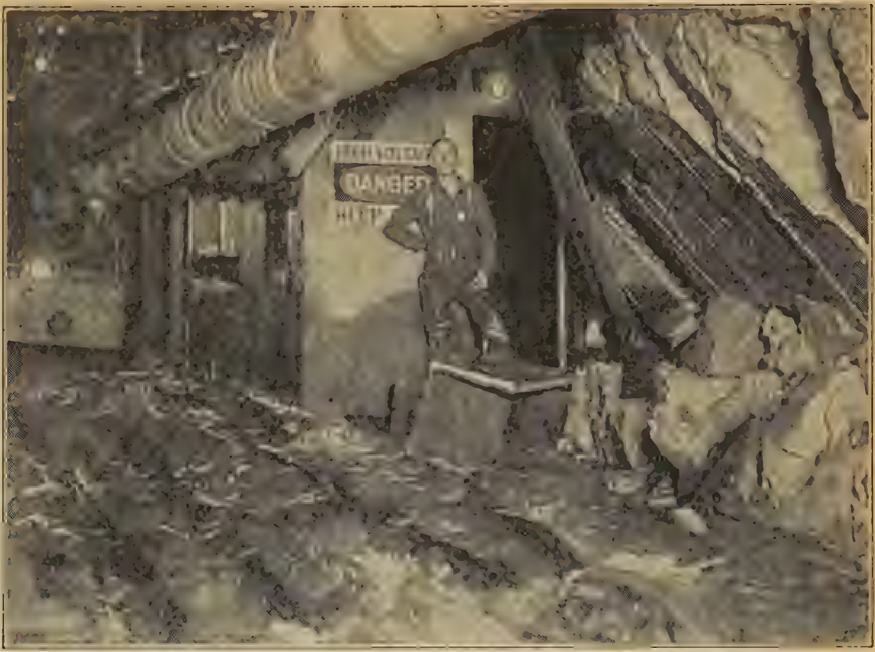

Fig. 30.—Water in Pioneer Tunnel Near the Scenic End, West Portal.

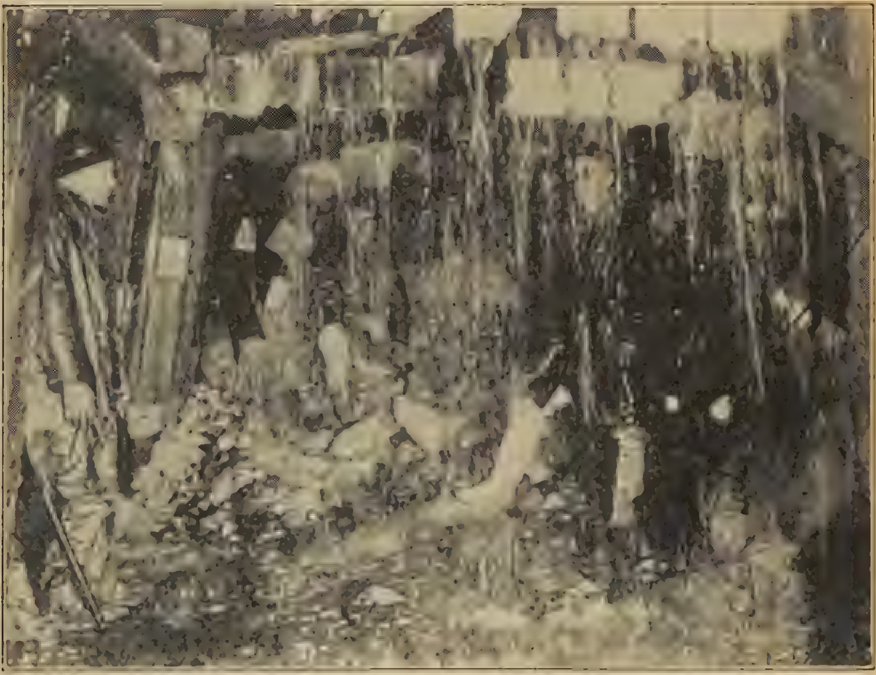

Fig. 31.—Water in Mill Creek Pioneer Tunnel.

The plan adopted at the west portal was to bulkhead the pioneer and force air into it with low-pressure fans in volumes ranging from 20 000 to 30 000 cu. ft. per min., the air passing through the pioneer to some advanced cross-cut where a bulkhead was to be erected, diverting the air current through the cross-cut into the main tunnel and thence out to the portal. The cross-cuts between the portal and the advanced bulkhead in the pioneer were to be closed. This plan provided the primary ventilation.

FIG. 32.—DIAGRAMS SHOWING CROSS-SECTION OF DRIFT DESIGNED TO CARRY LARGE FLOW OF WATER.

At an advanced bulkhead in the pioneer was to be installed a high-pressure fan, capable of delivering 12 000 cu. ft. per min. against a static head of 20 to 30 in. of water, taking air from the primary ventilation current and delivering it through a 20-in., 18-gauge, riveted and soldered ventilating pipe to the various advance heading operations, at the rate of about 4 000 cu. ft. per min. for each working place. Furthermore, at the advance bulkhead an equalizing fan was to be installed to pass the returning air through the bulkhead back into the primary ventilating current. This plan is shown diagrammatically in Fig. 33 and worked perfectly, with the following exceptions:

(*a*) The use of an advance bulkhead and the equalizing fan was found unnecessary. The primary ventilating current was simply allowed to find its way through the only cross-cut remaining open from the pioneer to the main tunnel and the high-pressure fan was set at this cross-cut, drawing fresh air from the primary

current at a point portal-ward from the cross-cut, the returning air finding its way back into the primary current.

(*b*) The high-pressure fans that were available, while delivering their rated capacities against the rated static heads, were too lightly constructed for the service and required heavy repairs. This is a detail, however, that can easily be corrected by the fan manufacturers in future installations of this character.

At the operations east and west from the Mill Creek shaft common pressure blowers forced air from the surface through 20-in. pipe, passing down the pipe road of the shaft and thence to the working places, the returning air finding its way back and up the shaft. This method is shown diagrammatically in Fig. 34.

At the east portal, while the center heading was being driven, similar pressure blowers were used, but after the center heading had been holed through, between the east portal and the Mill Creek shaft, dependence for a short period was placed on natural ventilation. This was found to be entirely unsatisfactory on account of changes in atmospheric conditions, which reversed the air current without warning. To overcome this difficulty the center heading was bulkheaded just east of the Mill Creek shaft and a fan was installed to maintain the ventilating current in a fixed direction.

All ventilating pipes were 20-in., 18-gauge, galvanized, with riveted and soldered seams, the length being connected by a special packed joint, as shown in Fig. 35, while for changing the air current from blowing to suction, reversing gates, as shown in Fig. 36, were used.

CAMPS AND FACILITIES

After having decided upon a plan of attack and a method of ventilation, the next step in the construction of a long tunnel is to provide adequate living facilities for the men required to carry on the work. In the case of the Cascade Tunnel, it was estimated that the maximum force would be approximately 1 500 men. The actual maximum number was 1 700.

The site of the tunnel is situated geographically in a mountainous region. The old main line of the Great Northern Railway lies in close proximity to the east portal and is about a mile from the west portal; and there is a highway over the summit from Scenic to Berne, impassable on account of snow during half the year. Before any real progress could be made, it became necessary to construct camps and service buildings, together with living quarters for married employees, at all points of attack. It was also necessary to construct a road, about 3 miles long, from Berne on the main line of the railroad to the Mill Creek shaft.

The buildings in all the camps were erected 6 to 10 ft. above the ground and connected with sidewalks for two reasons: (1) To avoid the tremendous expense of grubbing the natural surface; and (2) to aid in the disposal of snow which, in the vicinity of the tunnel, varies from 2 to 14 ft. in depth.

Each camp was provided with change houses, or "drys", equipped with steel lockers and shower baths, adjacent to the underground openings, and also with wash-houses and toilets conveniently spaced. The camps were all provided with running water for domestic use and fire protection, and with sanitary sewers discharging into septic tanks. They were electrically lighted, and the cook camps had electrically driven refrigerator plants for the proper care of food. Each camp was provided with a recreation building where various forms of entertainment, including moving pictures, were held and, in addition, there were buildings devoted to the use of the men for reading, writing, card playing, etc.

Adjacent to each camp a group of small buildings was constructed for the use of married employees, and in proximity to these buildings, a school-house and school teachers' dwelling. Each camp was provided with first-aid stations and an emergency hospital, presided over by a resident physician. Fig. 39 shows the general type of camp construction; Fig. 40 the type of toilet and change houses; and Fig. 41 shows the type of quarters provided for married employees.

POWER

One of the vital necessities for a successful tunnel-driving operation is a reliable source of power. There was no power immediately available at the site of the tunnel, and it was determined to commence all operations with portable gasoline-driven air compressors and lighting plants, pending a study of the power situation. This study developed that, in a few weeks, the Great Northern Railway Company could furnish sufficient power from its Tumwater hydro-electric plant, about 25 miles east of Berne, to carry the entire load of the east portal and Mill Creek operations at least during the first year, and that in the course of 8 or 9 months an adequate supply of power could be secured from the Puget Sound Power and Light Company for the west portal operations—this supply to be eventually carried over the summit and augment that secured from Tumwater.

In view of the long time that would elapse before power could be delivered at the west portal, it was determined to install a 1 200-h.p. Diesel engine-driven generating plant, producing 2 300-volt, 3-phase, 60-cycle current, to carry the west portal operations until power from the Power and Light Company was available. It was also determined to install at the Mill Creek shaft a 720-h.p. Diesel engine-driven generating plant as a stand-by unit, to furnish power for the shaft pumps at any time when the transmission line might be out of service.

In a few instances, during the period of maximum pumping from the Mill Creek shaft, the Power and Light Company's transmission line was out of service. On these occasions all tunnel operations were shut down, and the output of the Scenic plant, was carried over the hill to supplement the Mill

Creek plant and thus carry the pumps in the Mill Creek shaft. All power was either transformed to or produced at 2 300 volts and utilized at that voltage on all primary motors.

HAULAGE

All underground haulage in the tunnel operations was electrical, using direct current at 275 volts, furnished from motor-generator sets, spaced at suitable intervals.

All drifting operations were equipped with 6-ton, 24-in. gauge, trolley locomotives, supplied with gathering reels, holding 500 ft. of cable. The main tunnel operations were equipped with 20-ton, 36-in. gauge, trolley locomotives, also supplied with gathering reels holding 500 ft. of cable.

In addition, each working opening was equipped with one 6-ton combined trolley and storage-battery locomotive, which was kept on outside work, in order to be available for rescue purposes at any time the trolley line was out of service. All 2-ft. gauge tracks were laid with 40-lb. rail and 3-ft. gauge tracks, with 60-lb. rail.

COMPRESSORS

Compressed air was furnished for all operations by two-stage compressors, driven by direct-connected 3-phase, 60-cycle, 2 300-volt synchronous motors, the compressor capacity being as follows:

East Portal: Three 18 by 11 by 14 compressors:	
Total actual free air per minute, in cubic feet.....	2 850
Mill Creek Shaft: Four 18 by 11 by 14 compressors:	
Total actual free air per minute, in cubic feet.....	3 800
West Portal: Five 18 by 11 by 14 compressors:	
Total actual free air per minute, in cubic feet.....	4 750
Total actual free air, in cubic feet..............	11 400

STEEL SHARPENING

Steel sharpening shops were established at each camp and a general machine and repair shop for the entire work was located at the west portal.

The furnaces, both for forging and tempering, in all steel-sharpening shops were supplied with automatic-control pyrometers, and the blacksmiths were not permitted to use their judgment as to forging or tempering temperatures. This close control of drill steel-sharpening temperatures resulted in a remarkably low record of drill steel breakages, an illustration of which is shown in Table 7.

This practice of automatic control of furnace temperature and rigid instructions as to practice, was very difficult to enforce, as the blacksmiths were inclined to follow their own ideas. An example of one of these cases is shown in Fig. 42. The blacksmith decided to heat only the extreme ends of drill shanks with the result that breakage increased as shown. In the period, October 15 to December 3, inclusive, 67 045 drills were sharpened, and the number broken during the same time was 1 672. The total average breakage was 2.49%, as compared with the value of 0.59% given in Table 7.

DRILLS AND DRILLING LAYOUTS

Drilling in the various operations was done by many types of drills, produced by several different manufacturers. Great credit is due the American manufacturers of rock drills, who have produced what is perhaps, when considered from all angles, the most effective machine known to present-day construction. Fig. 44 is a view of drilling operations. Typical drilling and loading diagrams, which are largely self-explanatory, are shown in Fig. 45.

EXPLOSIVES

The next item of importance in tunneling operations, after drilling, is a proper explosive. In the Cascade Tunnel gelatine dynamite varying from 60 to 80% in strength, was used, in a total of 4 197 877 lb. In the tunnel 994 178 cu. yd. of rock were excavated, requiring an average of 4.2 lb. of per cu. yd. It is worthy of note, in this connection, that this large high explosive was handled without a single fatality.

ives were carried into the tunnel in rubber-lined and insulated , as illustrated to in Fig. 46. All primers were prepared by powder ing in isolated powder thawing and make-up houses, on the outside, ration. These houses were designed to be at least slow burning, ting stoves were in another compartment. Their construction is Fig. 47.

MUCKING

e of the restricted space available the work of removing broken rock ly called "mucking") is the most difficult operation to equip properly chanical appliances. With modern rock drills and explosives, little need be expected with breaking the ground, but under present con- di and labor for "mucking" on a long tunnel is not to be considered and lo machines that will work within the cross-section areas of drifts and fu railway tunnels are highly specialized machines.

ucking" in drifts was done by machines, such as illustrated in Figs. 48 . The best record of a machine of this type is the loading of 32 cu. ard, coarsely broken granite in 1½ hours, including the time occupied in cle g up the fly rock.

The "mucking" in the enlargement was done by rebuilt railway-type shovels operated by compressed air. The longitudinal and cross-sections of the general arrangement of these shovels are shown in Fig. 50. These were originally steam shovels mounted on two 4-wheel railroad trucks, which were removed and replaced with caterpillar treads. Their boilers were removed and replaced with air receivers.

The shovel engines were of the slide-valve type and in order to prevent freezing at the exhaust, the air receivers were equipped with eighteen direct-current, 220-volt, immersion heating units connected at 100 volts to prevent destruction by overheating. Each receiver was also equipped with an indicating thermometer, the indicating element being mounted in front of the shovel operator, together with a switch that controlled the heating elements, in order that the temperature could be kept within practical limits.

CARS AND SWITCHING

The success of all mucking operations in tunnels and drifts depends upon the speed with which cars can be switched behind the mucking machine. In the Cascade Tunnel the switching was accomplished by transferring the empty cars from one track to another with car transfer hoists. On the model of shovel used in the main tunnel these car transfer hoists were constructed on the rear of the shovel, as shown in Fig. 50, the switching operation being shown in plan diagrammatically in Fig. 51. For use in the drifts where mucking machines (Fig. 48) were used, special car transfer hoists, running on their own trucks, were designed and built. The design of these car trans-

fer hoists is shown in Fig. 52 and the switching layout is shown in plan diagrammatically in Fig. 53.

The cars used for conveying muck from the shovel in the main tunnel were of 6 cu. yd. capacity and 3-ft. track gauge (see Fig. 54). The cars used in the drifting operations for serving the mucking machines were of 50 cu. ft. capacity and 2-ft. track gauge (see Fig. 55). Both types of cars were the largest that could be used in their respective places and give adequate clearances.

PIPE LINES

The laying of pipe lines for compressed air and water is one of the lesser problems in tunnel operations, but still one of considerable magnitude, as the main air and water lines must be kept close up to the face, and the work of laying them must be performed without interfering with the major operation of drifting and enlarging the tunnel.

After careful studies of the pipe materials and supplies available, it was decided to use so-called "gas line" pipe, for all pipe lines more than 2 in. in diameter. This pipe is considerably lighter than standard wrought-iron pipe of equal diameter. It was connected with flexible couplings which were very easily applied, did not require any threading of the pipe, and permitted each length of pipe to be laid several degrees out of line. The use of this light pipe with flexible couplings was found to be entirely successful.

WORKING TIME

As the entire Cascade Tunnel operation had been laid out on the basis of securing "high speed", the work was run on three 8-hour shifts, and the shifts were changed, in the vernacular of the tunnel man, "at the handles of the drills", that is, every man stayed on duty until his relief actually took his place on the work, and the entire job throughout its progress worked three shifts on every day, including Sundays, holidays, the Fourth of July, and Christmas.

As the length of any tunnel operations increases, it becomes necessary to transfer men to and from work, and passenger cars consisting of flat-cars provided with a seat down the center on which two ranks of men could ride, sitting back to back, were constructed and used. These cars are shown in Fig. 56.

TIME CYCLE

The ideal time cycle per round in the various headings is well illustrated by that from the west portal pioneer taken on a day when five rounds were pulled and mucked in three shifts. The following tabulation of one cycle of operations at the Tye River heading on August 25, 1926, represents what was accomplished under ordinarily favorable conditions.

Time of blast	7:10 A. M.
Ventilation	27 min.
Enter drift, clean up fly rock with mucking machines and hand muckers	38 min.
Remove the main muck pile	1 hr. 22 min.
Remove the mucker and set the drill carriage	38 min.
Time required for drilling	1 hr. 17 min.
Load and retire	18 min.
Time of blast	11:50 A. M.
Total time required for one cycle of operations	4 hr. 40 min.

The men, equipment, and supplies used in this cycle were as follows:

16 men, including the shifter and the underground mucker boss.
28 loaded cars, capacity 50 cu. ft.
4 drills on a carriage, drilling in rock (altered granite).
195 lb. of 60% gelatine to load 28 holes with an average depth of 8 ft. 6 in.

The average advance per cycle was 7 ft. 6 in. for an 8 by 9-ft. cross-section.

CONCRETE LINING

When planning the construction of the Cascade Tunnel it was assumed that concrete lining would be required throughout its length; this assumption proved to be correct.

On account of the character of the ground certain parts of the tunnel required timber lining as the work progressed, some of which it was possible to remove immediately in advance of the concrete lining; other parts were left in place behind the concrete. The standard plan of timbering is shown in Fig. 57 and the standard section of the concrete lining, in Fig. 58.

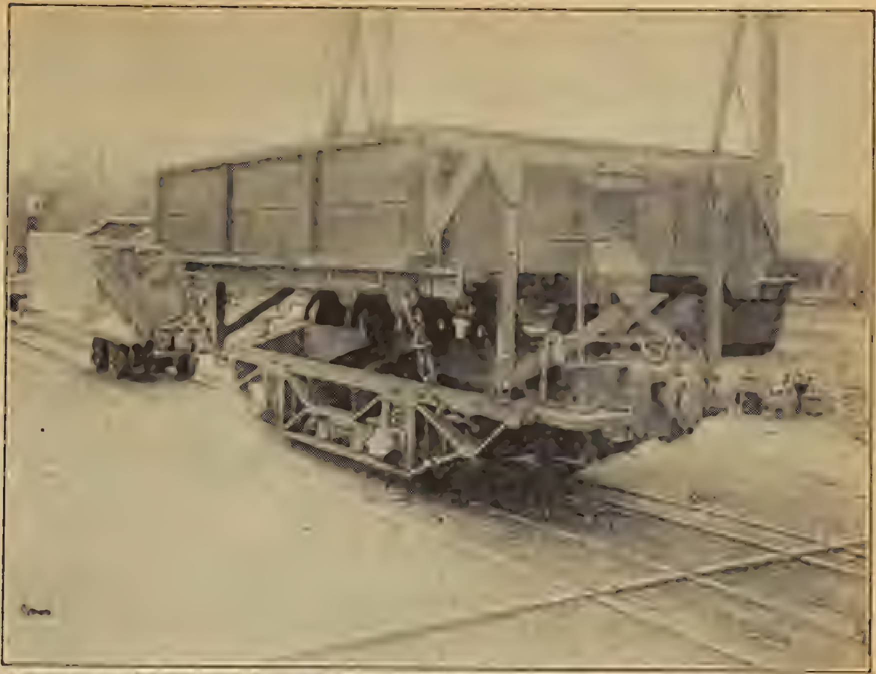

Fig. 54.—Six-Yard Cars Used for Conveying Muck from the Shovel in the Main Tunnel.

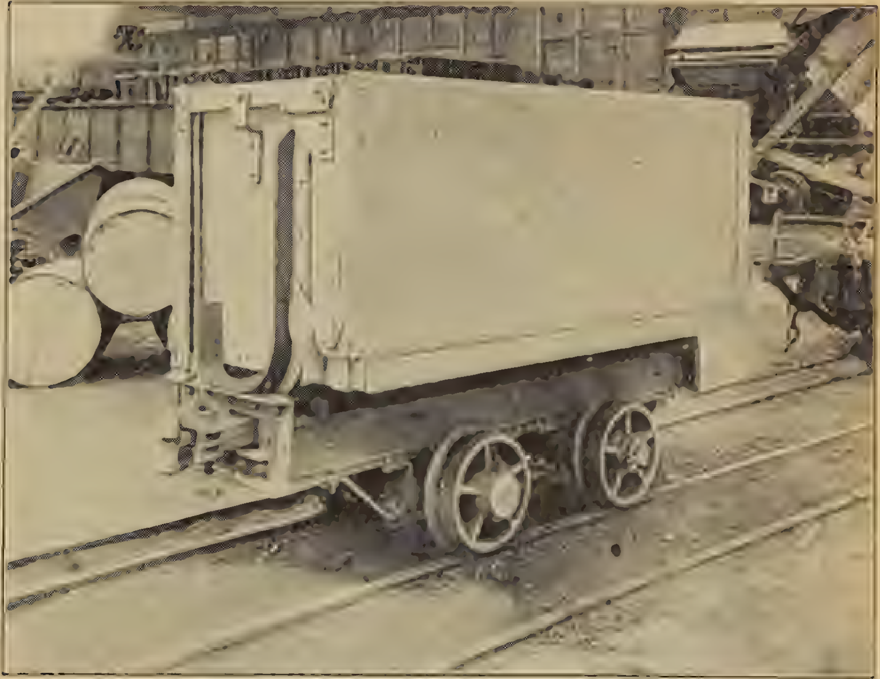

Fig. 55.—Cars Used in Drifting Operations, Cascade Tunnel.

Before designing the plant for placing the concrete lining the following governing conditions were determined:

(*a*) The rock from the tunnel, while all of a granitic character, was not suitable for concrete aggregate.

(*b*) While there were three openings into the tunnel, namely, east portal, Mill Creek shaft, and west portal, it was impracticable to pour concrete from Mill Creek shaft as this opening was approximately three miles from the railroad. Consequently, the entire concreting operations would have to be carried on from the east and west portals.

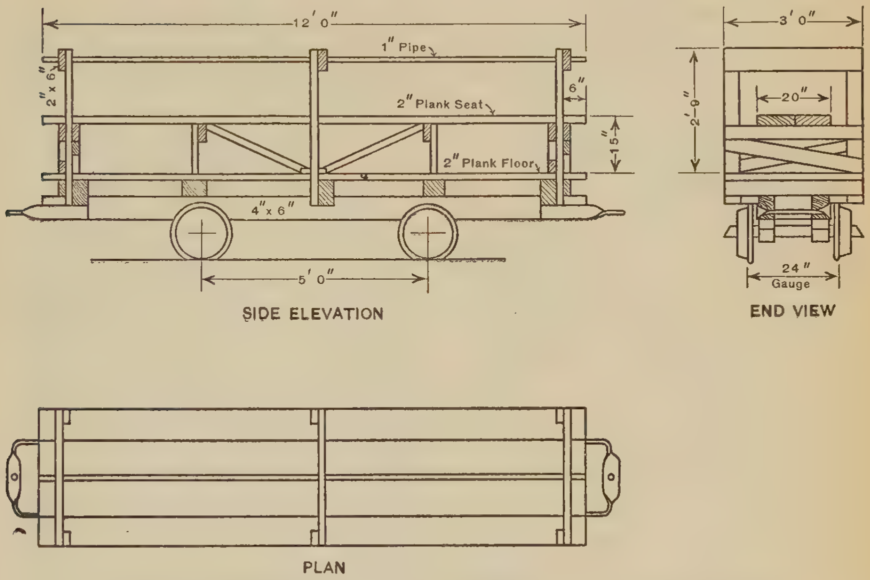

FIG. 56.—ELEVATIONS AND PLAN, PASSENGER CAR, CASCADE TUNNEL.

(*c*) As the tunnel required lining throughout and was to be completed in approximately three years the concrete plant must be designed so as to avoid interference with the main tunnel operations.

(*d*) On account of the length of the tunnel, it was probable that the concrete lining would form a junction approximately four miles from one of the portals. For this reason, it was deemed inadvisable to attempt to haul mixed concrete, the alternative being to operate mixers at the points where concrete was being poured, hauling the aggregate into the tunnel dry.

(*e*) On account of the conduits required in both walls of the tunnel it was deemed necessary to pour the side walls in two lifts to expedite the placing of these conduits.

With these conditions in mind the Great Northern Railway Company equipped its ballast pit at Reiter, Wash., to produce concrete aggregate from glacial drift, that is, natural washed sand, washed gravel, and crushed gravel, and arranged to deliver this material in standard bottom hopper railroad cars at the east portal and at Scenic about 1½ miles west of the west portal.

At the east portal the main line of the railway was contiguous to the tunnel operations and at that point a sand and gravel bunker was constructed, into which the railway cars unloaded by gravity. A similar bunker was constructed for the west portal, but as the main-line railway at the west end was 1½ miles from the tunnel portal the sand and gravel were rehandled over a 3-ft. gauge railroad to a second bunker at the tunnel portal. Both the sand and gravel bunkers were equipped with batching devices, using scale beams for sand batchers and volumetric batchers for the gravel. The batchers were discharged into batch boxes, four of which were carried on 3-ft. gauge flat cars. Each batch box was made with a vertical partition creating a compartment just large enough to hold the required quantity of cement for one batch. This compartment had a metal cover designed to prevent the cement, which was dumped from bags into the batch boxes at the batching plant, from coming in contact with moisture until it actually arrived at the mixer.

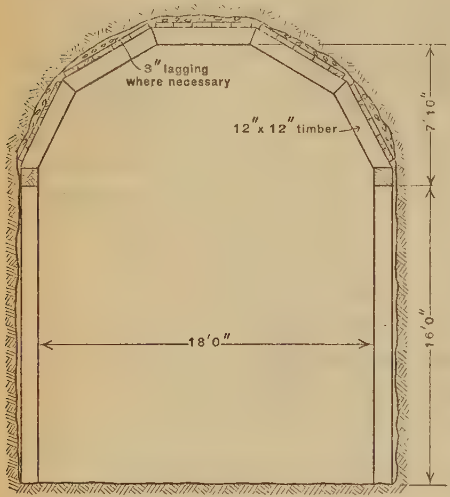

FIG. 57.—CASCADE TUNNEL: STANDARD TIMBERED TUNNEL SECTION.

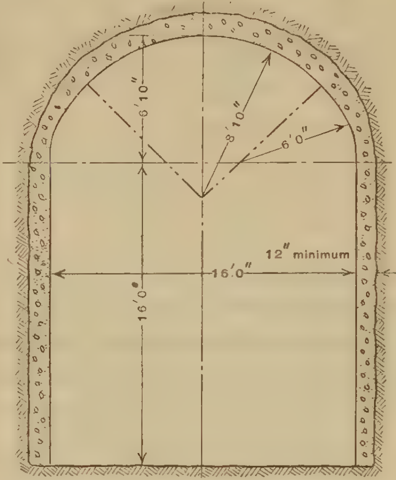

FIG. 58.—CASCADE TUNNEL: STANDARD CONCRETE LINING SECTION.

In general, the proportions of cement, sand, and gravel, used in the lining were 1 : 2 : 4, but these proportions were varied from time to time by the engineers to meet the varying characteristics of the aggregate. Practically all concrete had varying percentages of diatomaceous material added to improve its flowing qualities and the water-tightness of the lining.

A traveling steel form was designed[5] which permitted pouring of the side walls in two lifts and which completed 37½ ft. of tunnel at each move. The travelers for this form carried (in addition to the forms) hoisting apparatus, a 14-cu. ft. concrete mixer and air placer, together with various chutes and elevators, and permitted pouring of the lining up to the springing line of the arch by gravity, the arch itself being placed pneumatically. Cross-section drawings of these forms and their travelers are shown in Fig. 59.

Eight form travelers with their necessary equipment were used, three being operated from the west portal and five from the east portal.

---

[5] By and with the assistance of Blaw-Knox Co.

In laying out the concrete schedule for lining it was assumed that the forms should remain in place for 48 hours after pouring the last concrete in them. As the work progressed, this time was gradually shortened until movements of forms were made in 12 hours after the placing of the last concrete in that particular section. On numerous occasions, however, forms were struck in 10 hours and the records show the shortest time in which a form was struck to have been 8 hours after the final placing of the concrete. In no instance was there any evidence of damage to the concrete. For a detailed discussion of air placing of concrete in the arch ring, see Appendix B.

MISCELLANEOUS DATA

Before proceeding with the Cascade Tunnel a study was made of the possible rock temperatures that might be encountered, using the very highest geo-thermic gradient of which any record could be found (2° Fahr. for each hundred feet of depth). This study indicated that the maximum temperature likely to be encountered would not exceed 115 degrees. The actual rock temperature encountered was 75 degrees. Curves showing the original study and the actual rock temperatures are given in Fig. 60.

The degree of initial heating and the rate of cooling of concrete in the tunnel lining is shown in Fig. 61.

CONCLUSION

The Contractors were instructed to proceed with the construction of the Cascade Tunnel on Thanksgiving Day, November 26, 1925. Clearing and the construction of camps were commenced immediately and had advanced so far by December 14, that the approach cut for the west portal of the pioneer tunnel was started on that date. The approach cut for the center heading at the east portal was started on December 29, 1925, and the sinking of Mill Creek shaft on January 30, 1926.

Faller	$0.62½
Fireman	$0.62½
Foreman, Carpenter	$1.00
Foreman, Clearing	$0.80-1.00
Foreman, Concrete	$0.75-1.00
Foreman, General	$250 and board
Foreman, Labor	$0.75
Foreman, Mechanical	$1.00
Foreman, Rigger	$1.00
Foreman, Steam Shovel	$1.75 and board (outside)
Handyman, Surface	$0.60
Handyman, Underground	$0.70
Helper, Kitchen	$65, or $75 and board
Hoist Operator	$0.80
Inspector, Safety (Headquarters)	$200 and board
Labor Agent	$150
Laborer, Surface	$0.50
Laborer, Underground	$0.60
Locomotive Operator	$0.75
Mechanic, Master (Headquarters)	$300 and board
Mechanic	$0.80
Mucker Operator	$0.80
Plant Operator	$0.75
Powder Fitter	$0.80
Pumpman	$0.60
Rigger	$0.75
Saw Filer*	$0.68¾-0.75†
Shifter	$0.90
Stenographer	$100, or $125 and board
Storekeeper, General (Headquarters)	$150, or $175 and board
Storekeeper, Assistant (Headquarters)	$100, or $125 and board
Teamster	$75 and board
Timberman	$0.75
Timekeeper	$100, or $125 and board
Top Man (shaft only)	$0 60
Tractor Operator, 2-Ton	$125 and board
Tractor Operator, 10-Ton	$150 and board
Truck Driver	$100 and board
Team (rented)	$30, or $40 and board
Walker	$200, or $250 and board
Watchman	$60 and board
Waitress	$45 and board

---

* Board and sleeping accommodation = $1.35 per day. Men receiving rates, including board, were paid an allowance of $25 per month when boarding at home.

† This classification expired April 30, 1926.

The center heading, between the east portal and Mill Creek shaft, was holed through March 4, 1927, eighty-eight days ahead of schedule. The elapsed time on this operation was 430 days, during which 12 733 ft. of 10 by 10-ft. drift was excavated from two faces at an average rate of 14.8 ft. per day at each face, attaining a maximum month's progress at one face of 954 ft.

The pioneer tunnel between the west portal and Mill Creek shaft was holed through May 1, 1928, the final shot being fired from Washington, D. C., by President Coolidge. This operation was completed fifteen days ahead of schedule in an elapsed time of 867 days, during which 28 268 ft. of 8 by 9-ft. drift was driven from two faces, together with 21 cross-cuts, each 100 ft. long, or a total length of 30 368 ft., at an average rate of 17.5 ft. per day at each face, attaining a maximum month's progress at one face of 1 157 ft.

The enlargement between the east portal and Mill Creek shaft was completed 150 days ahead of schedule in an elapsed time of 452 days, during which 12 733 ft. of tunnel was enlarged to full section from one face, at an average rate per day of 28.2 ft., attaining a maximum month's progress at one face of 1 220 ft.

The enlargement between the west portal and Mill Creek shaft was completed December 8, 1929, eight days behind schedule, thus completing the excavation for the Cascade Tunnel, from which was removed 994 178 cu. yd. of rock.

Concrete lining was commenced from the west portal, April 27, 1927, and from the east portal, July 22, 1927, and was completed December 24, 1928, sixteen days after the completion of the excavation. The entire length of the tunnel was lined, a distance of 41 152 ft., at an average rate of 75.5 ft. per day, attaining a maximum month's progress of 3 002 ft. The total quantity of concrete placed in lining the tunnel was 275 218 cu. yd.

Track-laying and ballasting were commenced December 25, 1928, and the first scheduled train ran through the tunnel from east to west on January 12, 1929, 3 years and 47 days after the Contractors had been instructed to proceed with the work. From the date of instructions to proceed, to the date of the first scheduled train, the Cascade Tunnel was completed at an average rate of 36 ft. per day.

The opening of the tunnel was attended by a notable group of statesmen, railway executives, and engineers. To commemorate the occasion a remarkable radio broadcasting hook-up was arranged through thirty-two stations, over which speeches were made by President Hoover, from Washington; W. W. Atterbury, M. Am. Soc. C. E., President of the Pennsylvania Railroad, from New York; and J. B. Campbell, of the Interstate Commerce Commission, from Washington. When the first passenger train entered the tunnel the fact was announced by Ralph Budd, M. Am. Soc. C. E., President of the Great Northern Railway Company, speaking from the train itself. Thus was placed in service the longest railroad tunnel in the Western Hemisphere and the fifth longest railroad tunnel in the world.

APPENDIX A

DRILL-STEEL SHARPENING PRACTISE AT WEST PORTAL, NEW CASCADE TUNNEL

By H. J. King,[6] M. Am. Soc. C. E.

Description of Shop and Equipment.—The steel shop at the west portal was located between the 24-in. gauge service track leading to the pioneer tunnel and the 36-in. gauge track serving the main tunnel. A 24-in. gauge track leading from a switch in the pioneer track extended completely through the shop and beyond it into the machine and blacksmith shop located in the same building. The shop room, 32 ft. wide and 60 ft. long, was arranged with a view to minimizing the labor of handling steel in and out of the building and, at the same time, to give ample room for storage of bar stock and of made-up steel.

The equipment consisted of the following (see Figs. 64 and 65):

Three oil furnaces, equipped with pyrometer control, thermo-couplers, control-boxes, and magnetic indicators.
Two driller sharpeners.
One pedestal grinder.
One 250-lb. anvil.
One 3 000-gal. steel oil-storage tank (elevated).
One 1 500-gal. steel tank mounted on 3-ft. gauge, 6-yd. car truck (for transporting oil).
One 3 by 2 by 4 duplex pump (for handling fuel oil from tank car to storage tank).
Four platform trucks.
Storage racks for made-up steel.
Storage racks for bar stock (under shop).
Two quenching tanks (wood) for water (bits).
One quenching tank (steel) for oil (shanks).

Cutting-Bars.—Bars of 1¼-in. round, hollow steel, containing 0.78 to 0.85% of carbon, in lengths averaging 22 ft., were used for all primary drilling. A 1-in. hexagon steel of the same carbon content was used for stoper and jack-hammer steel. Bars were cut into the desired lengths by nicking them on opposite sides with a track chisel or cold cut. Then they were laid across the hub of an old 6-yd. car wheel and struck a smart blow with a 16-lb. hammer. Ragged ends of the bars on the shank end were then ground down to a square striking surface and properly chamfered.

Forging and Tempering New Bits and Shanks.—For forging shanks the pyrometer control was set at from 1 900° to 2 000° Fahr. About thirty bars of the same length were placed in the furnace and slowly brought to this temperature. Especial care was taken to avoid "soaking" the steel at high temperature. Only two or three steels were allowed to reach forging temperature at the same time, as oxidation takes place rapidly above 1 500° to 1 600° Fahr., with very harmful effects on the steel.

---

[6] Supt., A. Guthrie & Co., Inc., St. Paul, Minn.

After the bars were heated they were removed from the end of the combustion chamber farthest from the burner, placed in the sharpening machine, and upset sufficiently to give a bulb of metal large enough to form the shanks. The actual forging took place at temperatures between 1 800° and 1 900° Fahr. The steel must not be worked below a cherry red heat.

When the entire lot of bars had been "bulbed" they were replaced in the furnace and heated as before. The bulb die was removed from the sharpener and the shanking die substituted, after which the bulbs were forged to exact shank dimensions. The same methods and precautions were used for this heat as for the preceding one.

After the shanks were forged they were allowed to cool to well below a black heat. They were then reheated in the furnace with the pyrometer control set at 1 600° Fahr. and the hearth opening as wide as possible. The entire shank up to a point at least 2 in. beyond the lugs was brought to a temperature of 1 500° Fahr., tested on the magnetic indicator to prove they had been heated past the point of decalesence, and quenched in the oil bath.

Bits were forged in exactly the same manner except for the substitution of appropriate dies and dollies. The process of hardening the bits differed from the treatment of the shanks only in a slightly lower temperature (pyrometer set at 1 550° to 1 600° Fahr., with a 2-in. hearth opening). The steels attained a temperature of about 1 450° Fahr., and were quenched in clear, cold, running water.

Reconditioning Steel.—A round of steel, as it was returned from the tunnel to the shop for re-sharpening, consisted of from 24 to 36 sets of steel, varying in length by 2 ft., from 3 ft. to 13 ft. long, or 144 to 216 bars. These were examined both for broken bits and shanks, and if any were found, they were set aside for measurement and for cutting down to shorter lengths. Bent steel was similarly taken from the car for straightening. The remainder of the carload was placed on two platform trucks, each length being separated by wooden strips placed between layers. The trucks were wheeled to Nos. 1 and 3 Furnaces and sharpened. As steels were sharpened they were replaced on empty trucks and, subsequently, taken to No. 2 Furnace, reheated, and tempered. As truck loads of reconditioned steel accumulated, they were wheeled to the storage racks to await loading on the steel cars for further use underground.

As drill steel has a limited life and can be expected to begin breaking rapidly as the life limit is approached, it is imperative, in order to avoid concentrated breakage, that new steel be introduced into the stock regularly. Consequently, it was the practice to make up a small number of new drills in the longer lengths each day. Breakage, particularly shank breakage, is more pronounced in the longer lengths in steel of the same age. This is caused by the more serious effect of machines being out of line when using longer steel. In the comparatively easy drilling rock in the Cascade Tunnel very little bit breakage was experienced. As crystallization almost always occurred immediately at or below the shanks long before much change took place in the structure of the steel forming the body of the bar, the longer ones were cut down as they broke at the shank, to the next shorter length. Con-

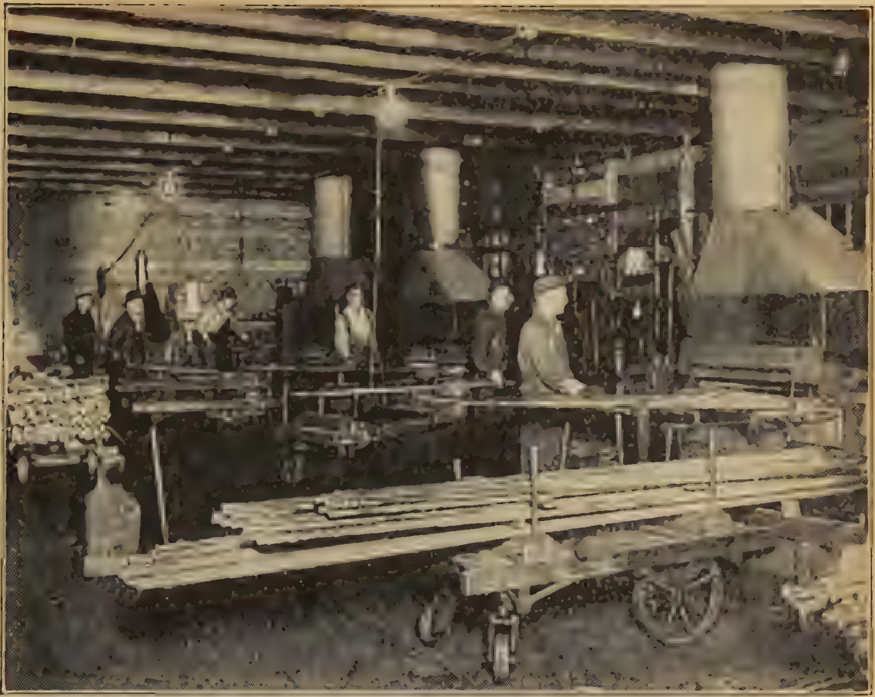

FIG. 64.—DRILL SHARPENERS, WEST PORTAL, SCENIC, WASH.

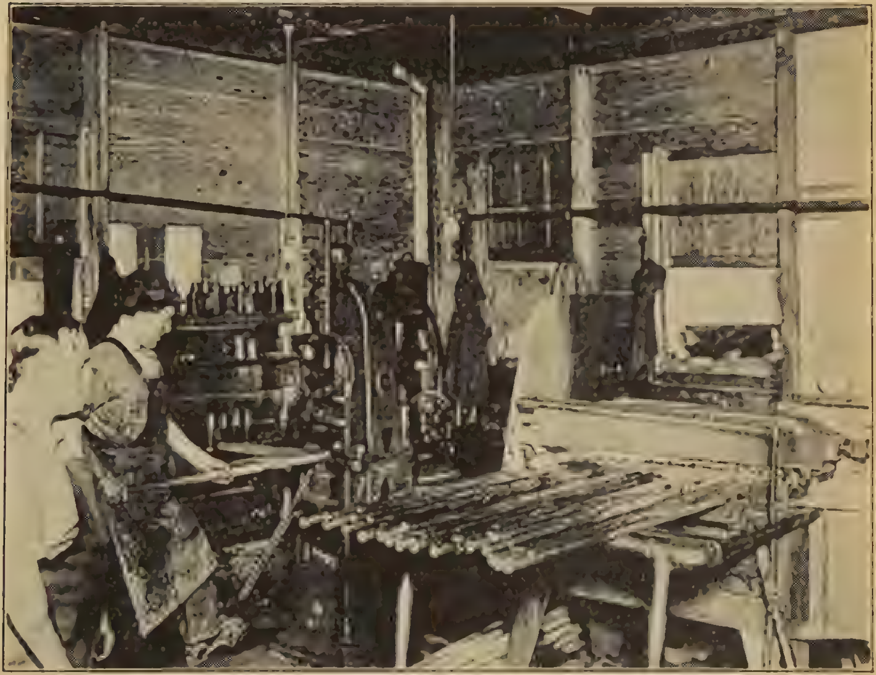

FIG. 65.—DRILL SHARPENERS AND FURNACE, SCENIC, WASH.

sequently, as time went on large quantities of the shorter lengths accumulated, particularly starters and 5-ft. steels. By the time a steel had been successfully cut down from 11 or 13 ft. to 5 or 3 ft., most of its useful life was gone. Consequently, actual breakage in the shorter lengths was greatest.

Where automatic heat control is used, as it was on the Cascade Tunnel, only two causes contribute greatly to premature breakage of steel. The first of these is the action of machines running out of line. Breakage from this cause cannot be attributed to faulty shop practice, and the remedy for it lies solely in the hands of those responsible for the operation of the drills. The second cause is due to using a drill with a pitted hammer face, or a face so badly worn down as to permit part or all of the hammer blow to be taken up by the lugs instead of the end of the steel. This is the largest single cause of premature shank breakage. An examination readily shows when this condition is present, and it is the function of the steel shop to remedy it by reshanking.

Selection of Personnel.—Experience at the Cascade Tunnel indicates that the old-time blacksmith or steel sharpener is often thoroughly saturated with worn-out theories and prejudice against any method or theory other than the one in which he believes. Consequently, it was found better to break in young, intelligent men with sufficient educational background to enable them to understand the theory of heat treatment.

APPENDIX B

PNEUMATIC CONCRETE PLACING PRACTISE IN THE NEW CASCADE TUNNEL

By H. J. King,[6] M. Am. Soc. C. E.

Description of Apparatus.—The pneumatic concrete placing machine used on the Cascade Tunnel (see Figs. 66 and 67) consists essentially of a horizontal steel cylinder, provided with an air-operated drop door through which the machine is charged, and an outlet opening recessed below the bottom of the forward end of the cylinder connected by means of flanges to the discharge line. A steel worm keyed to a heavy shaft is mounted in bearings in the ends of the cylinder at a sufficient height to permit the edge of the worm barely to clear the steel liner which protects the bottom side of the cylinder from abrasion. The worm is driven by a small motor mounted near the rear (or operator's) end, the speed being regulated by a train of gears in an oil-filled transmission case between the motor and the cylinder. The air inlet is situated at the rear end of the machine between the worm-bearing and the floor of the cylinder. A small air cylinder actuates the charging door, and the control of air supply to the cylinder is effected by a quick-acting valve which, together with the motor control, is mounted at the operator's end of the machine.

---

[6] Supt., A. Guthrie & Co., Inc., St. Paul, Minn.

Operation—First, the charging door is opened by the application of air to the door cylinder, and the proper volume of previously mixed concrete is allowed to flow into the cylinder. Before shutting the door, it is necessary to remove any concrete that may adhere to the upper side so as to prevent the escape of air between the door and the round rubber gasket ring upon which it is seated. This is best done by tapping the main air supply line and connecting a short length of ½-in. air hose fitted with a trigger nozzle. A quick circular motion around the edge of the door cleans it effectively with little or no loss of time. The door is then closed by reversing the piston travel in the cylinder. The worm motor is then started. After the worm has made two or three revolutions, the air-control valve is opened. As the air pressure builds up inside the cylinder, the concrete is moved forward by the worm and is finally forced through the outlet into the discharge line. No hard and fast rule can be set for the length of operation of the worm beyond stating that "the shorter the better". When they feel the movement of concrete start in the discharge line, some operators stop the worm for a few seconds, and then give it a turn or two just before shutting off the air. It should be borne in mind that the function of the worm is to deliver the concrete to the discharge recess in sufficient quantity to keep the recess full, and thus prevent the excessive use of air.

In theory, if the concrete is delivered to the discharge recess at exactly the same rate at which it is forced through the discharge line, it should move out as a solid plug. Owing to the fact that as the batch begins to leave the cylinder, the rate of delivery lessens, and also that there is a considerable loss of air through the concrete, the batch tends to separate as it moves along the discharge line, its velocity increasing as the dispersion becomes greater. It should be thoroughly impressed on all operators that they should try for minimum dispersion and that the continued feeding of air to the cylinder after the bulk of the batch is discharged is the principal cause of wear in discharge hose, bends, and nipples. It is the last of the batch which, moving at a very high velocity, impinges upon the walls of the discharge line, particularly at the bends which causes a large part of the wear. There is probably no class of construction equipment in the operation of which greater dependence must be placed upon the "feel" of the machine than this type of concrete placing machine. Minute differences in the quantity of water in the mix, and slight variations in degree of "harshness" of the aggregate, exert a profound influence on the operation of the machine; consequently, every effort should be made to provide a uniform mix. The addition of diatomaceous material to harsh aggregate materially helps in the operation of the machine, but experience in the Cascade Tunnel indicated that the excessive use of this material involved a penalty in the increased difficulty in making the mixture "stand" in the key of the arch. However, its moderate use with all but the smoothest aggregates is recommended.

Provided suitable aggregate is used, with proper measures to overcome any harshness, concrete can be placed with this machine dry enough to satisfy the most drastic specifications. The disadvantage of trying to handle sloppy concrete in the top of a tunnel arch generally results in a dry mix being used by preference.

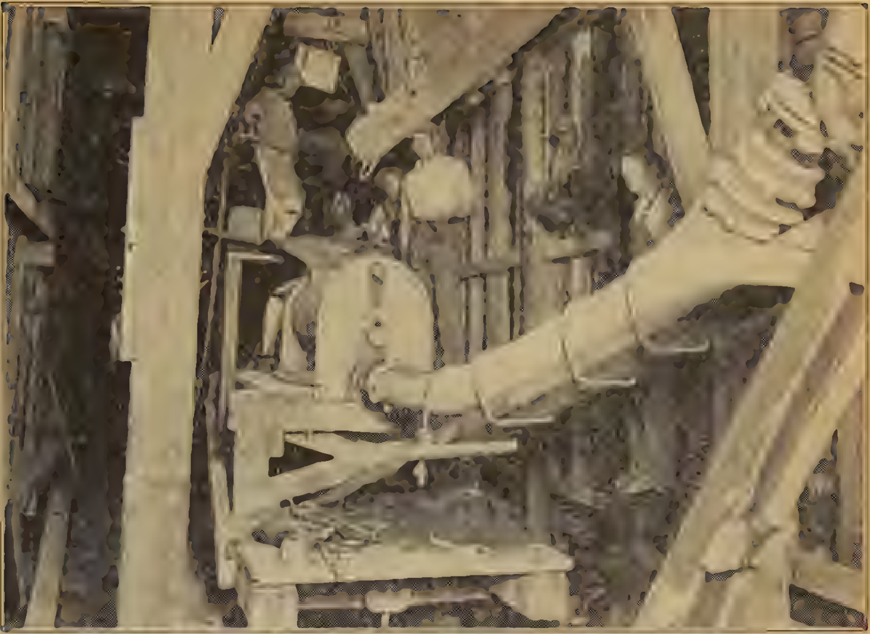

FIG. 66.—VIEW OF PNEUMATIC CONCRETING MACHINE USED ON CASCADE TUNNEL WORK.

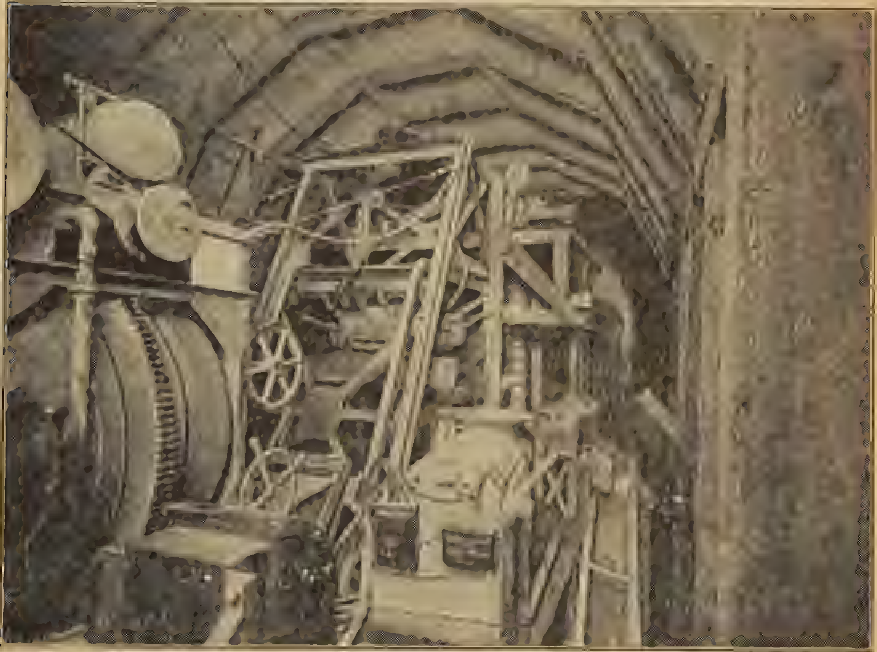

FIG. 67.—PNEUMATIC CONCRETING MACHINE SHOOTING CONCRETE INTO ROOF OF TUNNEL.

Aggregate—With concrete machines of this type, having a 6-in. outlet, the aggregate should not exceed 2 in. in greatest dimension. If the percentage of fractured material is great this should be reduced to 1½ in. Slabby pebbles and thin elongated pieces of rock are very difficult to pass through the machine, and aggregate containing very many of these should be avoided.

Fairly well-rounded, well-graded washed gravel should be procured if available, even at a considerably higher cost. The loss of time resulting from "plugs" in the discharge line is lessened materially, if not altogether avoided, by the combination of this class of coarse aggregate with smooth, workable sand. Great care should be taken to prevent the small pieces of wood, pieces of gunny sacking, etc. (which are often used to prevent leaks in railroad cars) from being placed in the concreting machine. These will invariably cause plugs. This also holds true for pieces of caked cement.

Discharge Lines—As a general rule, avoid abrupt changes in direction of the discharge line. Elbows should never be used. The more nearly straight the discharge line is, the greater will be the ease and certainty of operation, and the wear on the line is infinitely less. If changes in direction are unavoidable use long sweeping bends. Wear is greatest on the bottom of straight runs and on the concave side of bends; consequently, to insure uniform wear, a quarter turn should be taken on straight pipe occasionally and on hose bends after every pour of, say, 100 yd.

The makers of the machine recommend a specially built wire-wound rubber hose for discharge line. Experience at the Cascade Tunnel has proved beyond question that, for straight runs, wrought-iron pipe, extra heavy, will give considerably better service. Continued observation has indicated that the standard wire-wound hose gave reasonably good service until the soft, line-rubber, interior tubing was worn through. After this occurred wear was extremely rapid and a blow-out occurred within about an hour. When the wear penetrated to the spiral wire reinforcing it was only a question of a few batches until a plug occurred at the point of greatest wear. This was caused by the wire cutting in two, thus separating from the cotton hose wall and snarling inside the tube. With this in mind, it occurred to the writer that since no blow-outs had been observed, which could be traced to lack of wall strength, the wire reinforcing should be abandoned and its cost put into additional soft, line-rubber tubing. Consequently, a hose of the following characteristics was specially made up at a price considerably below that of the wire-wound product:

Weight, cotton fabric	32 oz.
Number of plies	8
Thickness of special abrasion-resisting rubber tubing	¾ in.
Length	5 ft. and 10 ft.
Diameter, internal	6 in.
Cost (f. o. b. Scenic) of one 10-ft. length, including nipples and clamps	$101.50

Thereafter, two lengths of this hose were used on each machine, the lower connecting directly to the concreting machine was 5 ft. long, and the upper connecting to the inclined discharge pipe was 10 ft. long. This combination gave the necessary flexibility of maneuver to that section of the line immediately above the form itself.

Due to the greater dispersion of material at the upper bend, greater wear was experienced at this point. Data were kept on the performance of a number of these hoses, the following being a representative and average test:

Date placed in service	September 22.
Date blown out	November 12.
Yards placed through hose	2 181
Hose[7] cost per yard	$0.0465

The lower bends were approximately 75% longer, although the angle of bend was the same.

A large number of 30° wrought-iron pipe bends were used as substitutes for the hose with greatly varying results. With extra heavy pipe, 5 ft. long, evenly bent its entire length, the wear of six pairs of bends gave the following average:

Average number of yards, upper bend	425
Average number of yards, lower bend	721
Cost per bend complete with flanges	$21.00
Cost per yard, upper bend	$0.0505

Two methods of patching worn-out bends were developed. The first consisted of welding heavy patches of steel over the worn spots. These patches when placed in service gave approximately the same results as new bends, but the practice was discontinued because after an indeterminate amount of wear the heavy patches blew off with grave danger to the crew working about them.

The second method was an outgrowth of the first and consisted of clamping several thicknesses of used placing-hose over the worn spot with heavy steel straps. This worked very successfully and as many as 750 cu. yd. were placed through the bends before the patches wore out. This method is effective in making a quick repair while pouring without removing the bend.

Patched bends, however, are the potential cause of plugs. In spite of a slight difference in cost in favor of the pipe bends (when patches are used), the fact that plugged discharge lines are much more infrequent with hose bends is the weightiest argument in their favor. Plugs in 99 cases out of 100 occur at bends. With the pipe all that can be done is to disassemble the line and clean it out. With the hose a few well-directed blows with a wooden maul at the point of obstruction will almost invariably release the plug. (This is not so effective with the stiff wire-wound hose). Another advantage of the flexible hose is the fact that thin spots can be located by feeling the hose, whereas there is no way of telling how badly worn an iron pipe is without getting at the inside.

Flanges.—Instead of using standard six or eight-hole companion flanges a slotted four-hole flange with attached swinging bolts was developed. These materially cut the time consumed in removing short lengths of pipe as the concrete advanced toward the forward bulkhead and prevented the loss of bolts and nuts.

---

[7] Hose given one-quarter turn after every 125 yd.

Care of Machine.—Although the number of moving parts in the machine are few these few need constant care to prevent undue wear. The standard worm furnished with a new machine is too light for constant service, the fin being made of ¼-in. boiler-plate spiraled around the hub and riveted to it through brackets. At the start of the Cascade Tunnel work these worms were a source of constant and annoying delays. (It is a 4 to 6-hour job to replace a worm.) In several cases the fin was torn completely off the hub by thin pieces of rock that jammed between the lower edge of the fin and the cylinder liner. This difficulty was remedied by the use of a specially designed worm cast of special abrasion-resisting steel with the fin ½ in. thick at the edge and ¾ in. thick at the junction with the hub. None of these cast worms broke and only two replacements were required in any machine because of wear. After the edge of the fin wears back more than an inch, the delivery of material to the outlet recess is so slow as to affect progress materially.

No trouble is usually had with the bearing (closed end) at the forward end of the cylinder, but frequent inspections are required to avoid trouble with the bearing at the motor end. The packing in the gland is quickly cut out by the air pressure forcing thin grout along the shaft. Lubrication must be attended to hourly by turning up the grease cup on the bearing. If this bearing and the corresponding bearing of the transmission case are not looked after the grout will work along the shaft and enter the transmission case. Two instances of the transmission case being almost filled by grout mixed with oil came under the writer's observation. In one case the grout had set so hard that the gear train was frozen in it. Due to the dust which is the usual accompaniment of concrete operations the motor requires more than ordinary care. When replacing the worm it is a very good idea to examine the liner plate and if it is materially worn to replace it at the same time.

Air Supply.—The results of experiments to determine the air requirements of this pneumatic concrete placer may be tabulated, as follows:

Number of batches poured	56
Size of batch, in cubic yards	0.565
Total number of cubic yards poured	31.64
Number of charges of machine	98
Amount per charge, in cubic yards	0.32
Quantity of air used, in cubic yards per minute	1 600
Length of time that air is used for each charge of the concreting machine, average in seconds	14
Amount of air used per charge of machine, in cubic feet	373
Air in cubic feet per cubic yard of concrete placed	1 134
Pressure, in pounds per square inch	105
Length of 6-in. placing hose, in feet	12
Length of 6-in. placing pipe, in feet	16
Combined length, in feet	28

With an air pressure of 105 lb. as used in this test, consumption would probably be a maximum. Experience at the Cascade Tunnel indicated that a compressor of much smaller capacity can be utilized if a good-sized air receiver is mounted near the concreting machine. Since the demand for air occurs at regular intervals it is practicable to build up a supply while the air-control valves are closed. High pressure is not essential to the successful operation of the machine; in fact, with adequate reservoir capacity the best results are had at a pressure of from 70 to 80 lb., and the apparatus will function very well with pressure at low as 60 lb.

Safety Precautions.—It should be remembered that the apparatus is periodically under rather high internal pressures and should be treated with the same respect as a steam boiler of equivalent pressures. Connections should be examined and tightened periodically (they have a habit of loosening from vibration), and flange threads should be inspected for wear. This is particularly important over the forms because the puddlers usually work in constricted quarters and have little chance to escape from bursting pipes.

When hose is used in the discharge line in proximity to wires carrying electric current the iron pipe near the discharge end of the line should be well grounded, thus avoiding the possibility of electrocuting workmen in contact with the discharge line above the forms.

DISCUSSION

R. H. Keays,[8] M. Am. Soc. C. E. (by letter).—The writer has been much interested in this Symposium, especially Part III, "Construction Plans and Methods." He only regrets that the description is not much longer, because there are no doubt many important features that might be elaborated.

The railroad authorities are to be congratulated that in the very beginning it was decided to line the Cascade Tunnel completely with concrete and not take chances with a timbered tunnel. Under some circumstances even the initial cost of a concrete lining might be less than that of timber.

The construction of this long railroad tunnel, by the use of a so-called pioneer drift (formerly known as the "two-tunnel system") supplies another example of the application of this method and well illustrates its advantages. Reference has been made to the method in connection with the Simplon, Rogers Pass, and Moffat Tunnels, the Simplon, of course, far antedating that of the other two. As adapted to these tunnels, however, the method shows some variations in detail, and the reasons for its adoption in each case may reveal some important differences.

It will be interesting, even at this late date, to review some of these reasons in the case of the Simplon. Going even farther back in history to the case of the St. Gotthard Tunnel (double track) it will be found that the highest rock temperature recorded was 30.7° cent., under a rock cover of 1 700 m. On the Simplon, the greatest rock cover was 2 200 m. (5 577 ft.) and, calculating from experience at the St. Gotthard, the highest temperature to be expected was 42° cent. On the other hand, to insure efficient service from the workmen in the tunnel, it was considered important to bring the air temperature in the Simplon Tunnel down to 25° cent.

At the time the construction of the Simplon was undertaken, it was realized that two tracks were necessary, and it was merely a problem of building one double-track tunnel, or two single-track tunnels. It was not necessary to start the second single-track tunnel, however, until the first was completed if a passing track were provided temporarily in the first tunnel. Therefore, the two-tunnel plan was adopted.

The only method considered to cool the tunnel was by ventilation with large quantities of air. For the supply of fresh air without regard to cooling, the total requirements were calculated at less than 5.0 cu. m. per sec. (176.6 cu. ft. per sec.), but to cool down to 25° cent., it might be necessary to provide for no less than 35 cu. m. per sec. (74 500 cu. ft. per min.).

Computations indicated that the total cost of piping such a quantity of air into the tunnel would be the staggering sum of approximately $7 000 000. Under these circumstances scarcely any calculations were necessary to determine that the best way to provide for the ventilation was to adopt the two-tunnel plan.

---

[8] Chf. Engr., Ulen & Co., Athens, Greece.

The Simplon Tunnel was constructed before the days of modern air drills. A bottom-heading method was used, the heading being drilled with rotary hydraulic drills. The tunnel enlargement drilling was entirely by hand methods. The lining is stone masonry.

As a matter of fact the rock temperatures found were much higher than calculated, amounting as a maximum to 55.4° cent. This, of course, made conditions intolerable, and it was necessary to supplement the cooling effect of the air by the use of large quantities of cooling water. An insulated water main, 25.3 cm. (10 in.) in diameter, was installed therefore in the pioneer tunnel. Through this pipe was pumped a maximum of 79 liters per sec. (2.8 cu. ft. per sec.). In addition to this pipe, there were two smaller insulated water mains for the conveyance of high-pressure water to the headings for use in the drills.

The water from the large pipe was used mainly to supply sprinkling nozzles installed in the main tunnel, between the last cross-cut and the enlargement operations. By far, the greatest number of men were employed in the enlargement, and it was necessary to protect them. These nozzles blocked the transportation to the heading of the main tunnel, so that it was necessary for all heading transportation to cross over to the pioneer tunnel at the cross-cut nearest the heading. The maximum water temperature at the nozzles was 17° cent.

Some of the cold water, however, was conducted to the headings and was used for sprinkling the walls and wetting down the outside of the ventilating pipes leading to the headings. The ventilation layout for the headings was similar to that described by Mr. Baxter for the Cascade Tunnel.

The foregoing information in regard to the Simplon Tunnel has been discussed in an interesting manner by Professor C. Andreae.[9]

Before dismissing the subject, the writer wishes to express his curiosity as to the reasons, in the case of the Cascade Tunnel, for estimating rock temperatures as high as 110° Fahr. If the Simplon Tunnel had any influence in this decision, it should be remarked that as far as rock temperatures are concerned Alpine tunnels seem to be in a class by themselves and of these, the Simplon was much the hottest, even allowing for its greater depth. Rock temperatures in mountain tunnels may have something to do with the age of the mountains, the Alps being of relatively recent origin.

The question of the quantity of air to be provided for ventilating purposes in an ordinary rock heading merits a few remarks. In many cases a large nominal quantity is provided for ventilation, until it is found that, due to light-weight pipe and leaky joints, only a small portion of the air reaches the end of the pipe; and then, of course, the advanced end of the pipe is not at the heading where the men are working, but is usually 100 ft., or more farther back. It is exceptional, therefore, for any of the low-pressure air to reach the heading. On the other hand there is always a supply of high-pressure air at the headings. During drilling operations there can be nothing in the heading but air from the high-pressure mains and during blasting operations the high-pressure mains are usually more or less wide open "to blow out the smoke". The function of the low-pressure air, therefore, is merely to hurry the smoke and bad air out of the tunnel after it has passed the end of the ventilating pipe.

---

[9] "Der Baulänger tieflingender Gebirgstunnel," Berlin, 1926.

In this connection, the writer knows of one important tunnel, in which a peculiar notion was stoutly maintained, probably by all the tunnel men. It was noted that after blasting (with high-pressure air discharging close to the heading and with the low-pressure system in operation at the same time), there seemed to be a wall of smoke maintained on the heading side of the end of the ventilating pipe and distant therefrom, say, 15 or 20 ft. The idea prevailed, therefore, that the operation of the low-pressure system held the smoke back and would not let it come out. After that the men actually went so far as to stop the ventilator during blasting, until all the smoke had been driven past the end of the low-pressure pipe by the high-pressure air from the heading. This was merely another case of things not always being what they seem. The true explanation is that the jet of air from the ventilator pipe instantly diluted all the smoke in range of the jet in the proportion of, say, 25 to 1, or more, so that the air in this zone seemed quite clear.

A variation of this idea is seen in the case of the tunnel superintendent who always had the high-pressure air line tapped with 1-in. nozzles at regular intervals all the way from the heading to the portal. All these nozzles were carefully pointed toward the portal and, after blasting, they were all opened with the idea of driving the smoke out of the heading. Then, there was the case of the superintendent who insisted on putting on a reverse bend at the heading end of the ventilator pipe, so that the jet would point toward the portal. In this case the only result was that he introduced so much back pressure that he practically stopped the air entirely.

J. G. SULLIVAN,[10] M. AM. SOC. C. E. (by letter).—Discussion usually implies some difference of opinion, but in the case of this Symposium the writer has only words of praise for the engineers and contractors who so rapidly and successfully carried this work to a satisfactory completion, especially in view of the fact that they had to contend with considerable quantities of water in a tunnel with a gradient entirely in one direction. Beginning in 1892, the writer had charge, as Assistant Engineer, of the construction of that portion of the abandoned line from the west end of the Scenic side-track to a point about half way to Tye. (See Fig. 2.) He has, therefore, taken a somewhat personal interest in the progress and outcome of this project.

It was gratifying to note that the contractors followed the plan of driving a center heading and radial drilling (see Fig. 19). When this plan was adopted for the first time, about 1916, in the construction of the Connaught Double-Track Tunnel on the Canadian Pacific Railway, it was rather severely criticized by some engineers of New York City.[11] Where rock is reasonably stable, this method is much more economical in the construction of a double-track tunnel than it would be in a single-track tunnel.

---

[10] Pres., Sullivan, Kipp and Chace, Winnipeg, Man., Canada.

Temperature.—The actual temperatures of rock in the Connaught Tunnel were practically the same as those shown in Fig. 60, although the distance from the summit of the mountain to the grade of the tunnel was about twice as great as that in the Cascade Tunnel. Before the Connaught Tunnel was started it was predicted by some engineers that serious trouble would be encountered from heat. They went so far as to predict an increase of about 1° Fahr. per 100 ft. of depth.

Double-Track vs. Single-Track.—The writer has the impression that the Great Northern Railway Company might have constructed a double-track tunnel. Using the center-heading and radial-drilling system of construction in rock that is reasonably stable, a double-track tunnel can be constructed at a cost not exceeding 125% of the cost of a single-track tunnel.

Since there is already a pioneer tunnel built for about 68% of the distance and considering that time in the construction of the second tunnel would not be an important factor, the second might be constructed for about 60% of the cost of the first tunnel. If these assumptions are approximately correct, and if the second track would be required within 15 or 20 years, depending on the cost of money, it would have been economical to have constructed a double-track tunnel in the first place; that is, of course, with the understanding that the nature of the rock was such that it would stand without support during construction. In the construction of the Connaught Tunnel it was found that, on account of the increased space, the time required for enlarging and lining would not be appreciably increased.

FREDERICK MEARS,[12] M. AM. SOC. C. E. (by letter).—The writer has noted Mr. Sullivan's remarks in regard to double-track *versus* single-track tunnel. A study of the present and probable future traffic over the Cascade Division of the Great Northern Railway showed that a double-track tunnel would not be warranted, particularly in view of the increased average speed of all trains over this district, brought about by electrification of 71 miles of main line—Wenatchee to Skykomish.

The extra cost of driving a double-track tunnel, as compared with a single-track tunnel, would have been far greater than the proportional difference in the cross-sectional area of the two tunnels. The nature of the rock was such that more heavy timbering, in advance of concrete lining, would have been required in a double-track tunnel than was used in the single-track tunnel, the side walls of which, in solid formation, were only 18 ft., face to face. Furthermore, the time limitation of three years would not have permitted the construction of a double-track tunnel in one operation. If it ever becomes necessary to construct a second tunnel to handle increased traffic, the pioneer tunnel, already built for 5.38 miles, could be used to good advantage in driving the second bore.

MEASURING IRRIGATION DELIVERIES IN THE PANJAB[1]

BY E. S. LINDLEY,[2] M. AM. SOC. C. E.

SYNOPSIS

The paper describes the conditions of Indian canals, as affecting the problem of distributing the supplies received in the manner desired. It describes the devices available for effecting such distribution with a minimum of manual control, mentions their principal qualities, and refers to the records of investigations directed to their improvement. An outline is given of the theories on which to base design in using such devices to form a complete scheme of automatic distribution; and, finally, their practical application is discussed, in so far as they are found possible under present limitations of knowledge and invention.

The method and means of measuring and apportioning irrigation deliveries, that are in course of development in India, and especially in the Panjab, are described. The writer, however, has not the local knowledge needed to judge whether, and how, these could be applied to American conditions.

GENERAL CONDITIONS

The irrigation canals of India are built, owned, and managed by the Government, which sells the water to the actual cultivators of the land served. The water is paid for at fixed acreage rates levied on the fields actually cropped on canal water in any season. The reason for this is that hitherto it has been impracticable to measure the water delivered to a holding, or even to a group of holdings, while field-to-field assessment was already in force for

---

NOTE.—The Special Committee on Irrigation Hydraulics selected the subject of "Irrigation Deliveries" as one of ten for study and research. This paper was submitted to the Committee by the author, and the Committee recommended its publication (see Progress Report of the Committee, *Proceedings*, Am. Soc. C. E., March, 1929, Society Affairs, p. 97).

[1] Published in February, 1931, *Proceedings*.

the rent or land revenue levied by the Government as the primary owner of all land.

Water rights are not fixed by volume, or by a rate of flow demandable at will. For each group of holdings a rate of flow is calculated from its area and other conditions. The canal system is designed to deliver these flows to all holdings when it is running full; when the supply is insufficient to fill the canal, the water is shared proportionately. For a variety of reasons, some local and some general, the simplest and best method of sharing has been found to be to keep each subsidiary channel running full or closed in short turns, for the correct proportion of the entire time.

The channels of a canal system fall into three classes: (1) Watercourses (farmers' ditches) serving the holdings that can be grouped together on one such channel, into not too large a unit; (2) distributaries and minors, feeding such watercourses; and (3) main canals and branches, feeding distributaries, but not watercourses. The distinction between Class (1) and Classes (2) and (3), is that the former is managed and maintained by the farmers, subject to the duty to keep the watercourses in good condition. The distinction between the second and third classes, both being managed and maintained by the Government, is that Class (2) channels are run full only to feed their watercourses correctly and automatically; while those of Class (3) may be run at any discharge, with the off-taking discharges controlled according to plan.

The supplies of the more important canals of the Panjab are secured by weirs; thus, they can be run up to their capacity as long as so much water is available in the river; but there is no storage for supplies in excess of momentary requirements. The canal systems vary in length up to 200 miles, and water takes as long as five days from the head to reach the last fields. (See Fig. 1.) Some canals have no weirs, so that they have to utilize the supply entering them from seasonal river levels. Many canals outside the Panjab are fed from storage of the monsoon flow of rivers which are almost dry for part of the year. This paper deals principally with the conditions of a large perennial canal of the Panjab. Fig. 1 shows the degree to which the Panjab plains are covered by canal irrigation. The areas commanded by "perennial" (weir-fed) canals are shown hatched; those commanded by "inundation" canals (fed only by natural rises of river level) are dotted.

The heads of main canals, branches, and main distributaries necessarily contain mechanism for the manual control of the supplies passing. The criterion in control has hitherto been satisfaction of the demand of those channels that were intended to receive supplies at any time. The correctness of these demands has been checked by periodical discharge observations at the heads of channels, and at the boundaries of the management districts. This method of check has become increasingly unsatisfactory as development of the irrigated area has caught up with the supply available. Deficiencies are due to the unavoidable errors of observation, considerable "personal factors", and accumulation or scour of silt which changes the rating curve. Progress is being made with the provision of meters to eliminate discharge observations. The task of calibrating existing works by individuals, or of designing standard calibrated works, is of old standing; the present tendency is to provide "semi-modular weirs or flumes" on the lines described subsequently and often by only a slight modification of existing works.

FIG. 1.—CANAL-IRRIGATED AREA IN THE PANJAB AS OF 1922.

The heads of minor distributaries were also controlled by hand, but it has now become fairly general to effect distribution at such points automatically, by pairs or groups of semi-modular flumes.

The heads of watercourses, or "outlets", were originally mere open cuts in the distributary bank. Several decades ago pipes and culverts in the bank were substituted for these cuts; and it is instructive to note that at the time this substitution met as much opposition as is now offered by some to more modern ideas. The discharge of such outlets was dependent on the water level, both on the distributary and the watercourse side. While the former was relatively constant, especially under a policy of running a full supply or nothing, the latter was liable to considerable variation, according to the level of the field being irrigated, and to the state of neglect or clearance of the water course, depending on keenness of demand. The heads available did not make it generally possible to eliminate the effect of water level on the watercourse side by setting the outlets with a free fall. The first suggestion for a device with which hydraulic principles might be used to provide a virtual free fall was made about 1908, and, at present, automatic distribution is being rapidly improved by extending and improving the use of such devices.

The question is no longer "whether", but "how". The "how" is still in the stage of trial and intense discussion, both as to general policy and details; but there is sufficiently full and concrete accomplishment by which to report and study.

Beyond the outlet, discharges are, in general, not subdivided; the supplies are managed by the farmers whose holdings have been grouped together. The individual farmer takes the entire discharge in turn according to an agreed roster.

It is to be noted that development and the intensification of demand were greatly stimulated by the World War; at the same time, this condition gravely restricted the funds available for experimenting and improvement, and called for the services of so many men that those who were left, were fully occupied with ordinary current duties. These conditions have been eased only since 1926 so that much of the progress made, has been accomplished in the face of unusual difficulties.

It is also to be noted that a canal in charge of an engineer, with only Indian assistants and staff, receives on the average approximately 1 500 cu. ft. per sec., which has to be given to about 1 500 outlets. Within a year this quantity actually irrigates about 400 000 acres, in an area as large as about 1 000 sq. miles. The duties include not only what is obviously to be expected of an engineer in such a charge, but also administrative work, such as stopping waste or theft of the water, and field-by-field measurement for the assessment of water charges. Administrative methods include a system of forms and returns, and written orders and reports, beside which the routine of a European governmental office is child's play. These duties have to be fulfilled before time can be found for investigations.

THE DEVICES USED

The term, "module", as used in this paper, is defined as a device designed to deliver a constant discharge, independent of fluctuations of water level or pressure on either the supply or the delivery side.[3] The first to develop any of the devices that have proved of practical importance was the late Mr. R. G. Kennedy, of the Panjab Irrigation Department, whose investigation of channels that just carried their silt charges without scouring, is widely known. He first devised three types of "modules,"[4] for big, medium, and small discharges, covering the entire range of requirements. Of these, the medium and small types involved regulation by balanced cylinders suspended from a weigh-beam, and have not proved suitable for practical work. The largest consisted of a gate swinging on a horizontal axle, with a counterweight linked to an extension of its upper end and running on a guide-rail laid to a curve calculated and confirmed by experiment; and the basin under the bottom of the gate was also formed to a longitudinal curve. Any given difference of up-stream and down-stream water levels brought the gate to some position predetermined by the counterweight and the curve of its guide-rail, and the basin graduated the aperture at each position so that the desired discharge would pass. The device was made in several sizes, and each could be set to furnish the discharge desired, by giving the correct amount of counterweight.

---

[3] Panjab Eng. Congress (1923), p. 45.

[4] Panjab Irrigation Branch *Paper No. 12* (blue), of 1906, "On the Distribution of Water for Irrigation by Measurement".

This "gate module" was used for a few distributary heads, which then had to be equipped with modules for special reasons. It seems to have functioned quite satisfactorily, but when it had removed the difficulties that led to its installation, it was gradually forgotten and ignored. At one site, conditions (not concerned with the module) led to so much silting that the water levels rose above those that the module was intended to control. The device was removed because those concerned did not know how to put it right. Efforts are now (1931) being concentrated on regulating discharge at outlets; at minor heads, needs are more simply and probably better met by flume furcations; at distributary heads, similar flumes to meter manually controlled supplies seem to satisfy present requirements. This device, therefore, may be said to have been "born before its time", and thus far seems to have met the usual consequences. Fig. 2 shows a pair of flumes dividing the tail flow of a distributary between two form ditches. The one in the foreground has not quite a free fall, but the flow at the tail of the flume is unsubmerged. A standing wave is formed a little below the narrow throat. Distribution between the two is the same as if both had free falls.

A "gauge outlet", devised by Mr. Kennedy in 1908, is the first of the "semimodules", which differ from modules proper in rendering discharge independent of water levels on the down-stream side, the natural variation with water levels on the up-stream side continuing in accordance with the hydraulic law. As the down-stream variation is the greater, and is largely controlled directly contrary to regulation policy, this class of device does more than one-half the work of a module.

This gauge outlet[5] may be described as a modified Venturi meter. The modification consists in providing free admission of air all around the throat, so that static pressure in the jet at that point cannot fall below zero. There is the usual recovery of kinetic energy in the expanding down-stream section, so that zero pressure is possible at the throat when that is lower than the delivery water level. It will be understood without lengthy explanation, that the discharge is independent of down-stream levels as long as the difference of head is sufficient to draw the throat pressure down to throat level; if it is sufficient to draw it lower, air bubbles will be attracted into the stream, and the excess head will be wasted. The discharge then depends only on the depth of submergence of the throat by the supply level. The outlet is not adjustable, but the desired discharge can be given by setting it with the necessary submergence, subject to the maximum allowed by the difference of head available.

The outlet has been widely used. It has brought about a considerable improvement in distribution, and blazed the way for most of the further work that has been done on this subject in India. After it had shown that the needed improvements were possible, however, certain defects gradually became apparent.

---

[5] Panjab Irrigation Branch *Paper No. 12* (brown), "Results of Tests of Mr. Kennedy's Gauge Outlet"; together with addenda on its improvement, protection, and application.

From the beginning, the most serious defect has been that it is perfectly easy to stop the air supply to the throat, in order to increase the supply received. In the absence of any public opinion among the Indian peasantry, it is difficult to deal with this interference, and impossible to stop it. Some means of meeting this defect have been devised, but the outlet has fallen completely out of use in the Provinces with which the writer is in touch, and he has heard nothing of any actual use of these newer models.

Other defects are the natural result of the textbook theory that dictates the measuring of the head which causes velocity, down to the center of the orifice through which the water flows. To make it theoretically an orifice discharging freely into air, Mr. Kennedy provided an enlarged section in the throat in such a way that a supply of air surrounds the jet. He seems to have assumed that the top and bottom of the throat would be aerated simultaneously; and he claimed that the appearance of air bubbles in the discharge was a certain and simple indication that the device was discharging as designed. In unpublished tests the writer has found that, between the condition in which discharge was fully dependent on difference of water level with no air bubbles passing, and that in which it was fully independent of downstream level with air bubbling freely, there was an intermediate condition with discharge less than the theoretical, but with bubbles appearing.

A further result of following this "center of orifice" theory involved no practical defect, but is of interest. Mr. Kennedy calculated the coefficient of discharge from observed discharges and submersions measured from the center of the orifice as zero point. He was impressed by the fact that the values of the resulting coefficient were so low, and that the coefficient decreased with decreasing head. The writer plotted $\sqrt{}^{2}$ against water level, and found that if the zero point were taken at almost two-thirds of the height of the orifice, the coefficient was constant down to quite small submersions, and that it had a reasonable value for the bellmouth used. Another instance in which the writer was able to point out that the "center of orifice" theory had been misapplied, was the calibration of the sluices of the Assuan Dam.[6] The same error had also been found in investigating relatively short pipes discharging freely into air.[7]

Both these two last points would be avoided by making the orifice rectangular, or at least aerating only a flat top, as in the standing wave orifice semi-module mentioned subsequently in this paper.

A defect that is not yet generally felt, is that the discharge can only be adjusted by means of the depth of submersion, which should be fixed by other considerations to be discussed later. That defect is overcome by another form devised by Mr. Kennedy.[8] In this form the throat which constitutes the

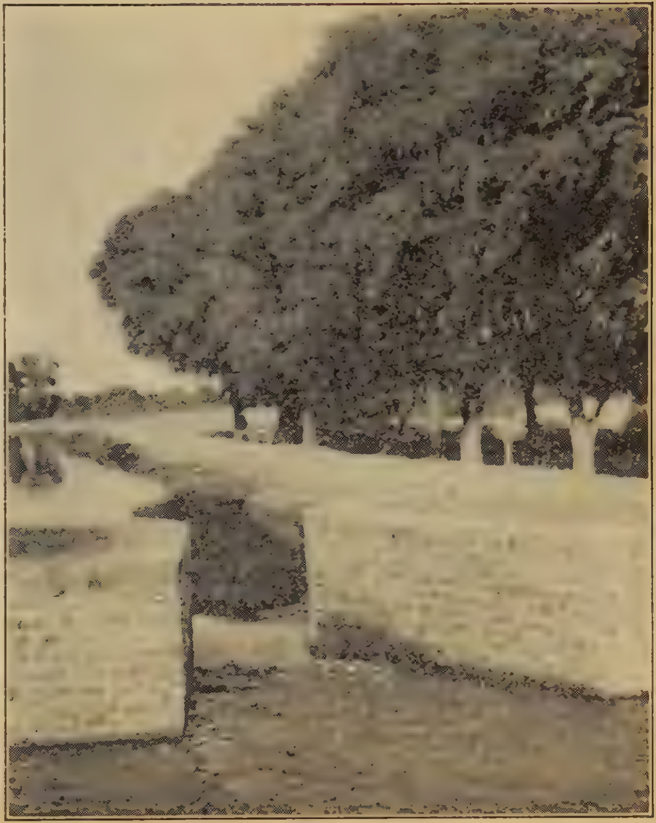

FIG. 3.—A STANDING WAVE FLUME.

measuring orifice, is set vertical, and a cone is suspended in it for the purpose of adjusting the area available for flow. This form has not been brought into practical use, within the writer's knowledge.

In about 1906, Mr. A. S. Gibb, formerly of the Panjab Irrigation Department, devised what is believed to be the only true module in which nothing moves but the water.[9] A flume of rectangular section follows a circular arc. The flow, therefore, must be part of a free vortex, and the surface of the designed discharge can be calculated. Vanes are set across the flume, leaving the designed discharge free, but skimming off any excess and turning it toward the center and causing turmoil. This module must be set unsubmerged by delivery levels; the supply water level must be high enough to give the designed velocity, and must not exceed this by more than the amount of head that the vanes provided can waste. It is not made adjustable for discharge, but is designed for discharges varying by small steps.

The use that has been made of this module is, as far as the writer is aware, practically confined to complete regulation of one long channel in which the distribution among watercourses gave great trouble with ordinary culvert outlets. Naturally, the cultivators who had their former excessive supplies reduced, raised objections and made constant complaints. Judged by the standard of the time (the supply that reached the tail of the channel), the measure was a great success in that the tail received rather more than its share, with rather less than designed discharge admitted at the head; and the same is still the case when, for a number of years, the local engineers have not had to give the channel special attention.

However, the fact as stated indicates that some outlets receive less than their share. The earlier forms of the module were found to be slightly incorrect, but have been replaced by a later form. A recent inspection showed that some farmers were apparently getting too little water because delivery levels now submerged the modules; and others were apparently getting too much because supply levels had now risen above the modular limit. The last two facts indicate slight disadvantages to weigh against the simplicity of the device.

What is known in America as the "Venturi flume" was originated earlier and independently by the late Dr. A. A. Stoddard and the late Mr. W. B. Harvey, both of the Panjab Irrigation Department. By introducing a smooth hump on the bed, or smooth contractions of the sides of a regular channel, a dip in the water surface is produced equivalent to the head converted into increased velocity. Knowing the areas of the up-stream and throat sections, and the amount of this dip, the discharge can be calculated; but by the standing wave theory which is now widely known, V^2, at the throat, cannot exceed $g \times d$. Therefore, if the contraction is sufficient, conditions from the throat upward are fixed; below it, a standing wave forms and wastes any excess energy, and the device is a semi-module with its discharge constantly dependent on the up-stream water level only.

---

[9] Panjab Irrigation Branch *Paper No. 13*, "Gibb's Module; Report on Its Working on the Shahkote Distributary.

In the Panjab, this device was first introduced to distribute supply among the outlets grouped at the tails of distributaries. These supplies are even now variable; therefore, the first need is to distribute them proportionately, in spite of differences between, and fluctuations of, delivery water levels. This need would not be met at all by the two-gauge Venturi flume, and the one-gauge standing-wave flume has been the one developed. Fig. 3 illustrates a standing wave flume used for automatic semi-modular division of supply between two small branches. The flume shown in the center is discharging about 30 cu. ft. per sec., with an up-stream depth of about 2.5 ft. With an afflux of less than 6 in., it is discharging as if it had a free fall. "Modularity" with small working heads was the first desideratum, and as the difference between ordinary and extreme efficiency meant only a difference of about 0.1 ft. in maximum permissible delivery level, even this demand was mild. Accuracy of discharge was not at first very important because the discharges dealt with had been subject to 100% variation and a reduction of this to, say, 20%, satisfied all concerned. Both have become much more important since the device has been used on a much larger scale. The *prima facie* simplicity of elementary theory is found to be complicated by points that this theory ignores; and much important work has been done to perfect the device.[10]

The simultaneous investigation of the device in America has concerned itself more with the two-gauge Venturi flume. Recently, advance seems to have led more to the one-gauge flume.[11] It seems to the writer that the ample resources available for American research would achieve even more valuable results, if a study were also made of what engineers in India have accomplished with very cramped resources.

When Messrs. Stoddard and Harvey originated their flume, they also devised an orifice gauge outlet based on the same principle. In this, a bellmouth leads to a rectangular orifice; instead of the closed expanding pipe of the outlet as developed by Mr. Kennedy, this continues as an open flume the bed and sides of which carry on those of the orifice. Under appropriate conditions, a standing wave forms in the flume, leaving the orifice free to discharge into air with a supported jet.

The outlet has the advantage of extreme simplicity; but under many conditions a relatively large working head is necessary for the standing wave to form. This led Messrs. Stoddard and Harvey to concentrate on an attempt to make smaller heads sufficient. These attempts produced some extremely ingenious ideas, but achieved no practical success. In spite of this limitation, the outlet[12] had a considerable field of utility in this simple form, and has been used successfully. A further considerable advantage is that the outlet is adjustable, by making the roof of the bellmouth and orifice slide up and down the sides. A special form was also constructed,[13] which diminished the working heads needed by using the outlet with shallow submergence, for proportional distribution of supplies. The relative advantages of that and other distributions are discussed in this paper.

[12] Panjab Irrigation *Nomograms*, Pl. 45*a*, and the pamphlet of the manufacturers.

After considerable further work by other engineers, the problem of saving head seems now to have been solved by Mr. W. Kirkpatrick, of the Bombay Public Works Department. He sets vanes across the flume of the outlet, with their lower edges on an incline rising from the orifice. These help to support the standing wave, and the orifice is free with a satisfactorily small working head.[14]

A number of devices have not been mentioned which, like Kennedy's two smaller modules, have never found application and seem unsuited to irrigation conditions in the field. The same applies to devices that are really only minor modifications of the originals described. The literature that has been quoted in references contains brief descriptions and references to any published, more complete descriptions.

Only one further group of devices calls for mention here. One is a module intended for outlets, which is now used to regulate a constant supply for sand filters. It is of the type in which a piston "floats" on the difference of head across a fixed orifice, and as it moves it adjusts a second orifice so as to waste more or less head and keep the former head constant. It has been tried in the Bombay Presidency and is understood to have proved unsuccessful because of the long streamers of weed that grow in the water and the colloidal mud which accumulates on the guide-rod for the floating piston. It was applied to the outlets of a small distributary in the Panjab and this installation has never been properly examined since, but on one occasion the writer had the opportunity to go over the channel and found distribution still satisfactory.

A second device is a module intended for large discharges. It is a Venturi meter provided with a butterfly valve a little down stream from the throat. The valve is actuated by reversible mechanism controlled by the Venturi head, set to be stationary at the designed head, to close with greater head, or open with smaller heads. A few were installed for trial in Bombay, but the writer has not had any certain report of their working.

The Venturi meter has been used for some very large discharges in Southern India and is believed to be satisfactory. In the Panjab its field is filled by the flumes described herein.

METHODS OF USING THE DEVICES

At first, "moduling" was done for outlets individually; but methods of collective use have since been developed, so that the supply admitted at the head of a canal is automatically distributed to the outlets on it. At first thought, it might appear that if modules were fitted to the head of the channel and to all outlets, this result would be simply secured; but no positive module has yet been definitely shown to be so reliable and satisfactory as to justify the cost. Even if that were the case, fluctuations would still have to be faced, as, for example, when cultivators close their outlets for silt clearance without notice, or when channels have to be overloaded temporarily while a breach is repaired.

---

[13] Panjab Irrigation Branch *Paper No. 26*, 1922, "Moduling of Irrigation Channels," by E. S. Crump.

[14] Bombay Public Works Dept., *Technical Paper No. 12*, "Jamrao Semi-Modules," by W. Kirkpatrick.

The ideal aim for a plan of "moduling" a distributary may lie anywhere between two extremes: One is to give each outlet and the distributary the full designed supply, and to close the distributary as required; the other is to give each outlet its correct share of the supply passing at the moment. The former is theoretically possible; but for practical reasons referred to previously, it is accepted by all as necessary to fit the tail group of outlets with flumes in order to distribute proportionately the supply reaching them. With the devices available, the latter ideal is theoretically possible only by means of a pair of flumes at each outlet, distributing the supply proportionately between the outlet and the distributary. As this would involve a small drop of distributary supply level at each outlet, it is not really practicable. What is practicable and practised is to assume that the supply level corresponding to a given discharge is constant, and to fit each outlet with a semi-module intended to take off the proper proportion of supply as long as this holds good. As the assumption in practice fails to a varying extent, this latter ideal is not fully possible; but before proceeding to more detailed discussion of the two extremes and of intermediate possibilities, it is necessary to state the theory of the subject that has developed.

THEORY OF GROUP DISTRIBUTION

This theory is based on the idea of proportionality, which is most simply explained in algebraic form.

When giving each outlet a fixed proportion of the supply, if D is the designed supply of a distributary and if nD is the designed supply of the outlet, when $D \pm d$ is the actual supply in a distributary at any moment, then the outlet receives $n\ (D \pm d)$ gal. of water per hour. It is always necessary to provide that the outlet shall receive nD gal., when D gal. are available; but fluctuations can be otherwise dealt with, and if the outlet receives $n\ (D \pm rd)$ gal. of water per hour, the fraction, r, is by definition the "proportionality".

It has been found that the discharge of silt-formed channels in the Panjab varies almost exactly as the $\frac{5}{3}$ power of the depth.[15] If an outlet is a flume in which the discharge varies as the $\frac{3}{2}$ power of the submergence, set with its sill at one-tenth the designed supply depth above the distributary bed, with the width such as to give the correct discharge at the designed supply, the curves for proportional and actual discharge would be tangential; and since the two exponents, $\frac{5}{3}$ and $\frac{3}{2}$, are not very dissimilar, the two curves do not diverge enough to call for practical objection; that is, such a flume is a semi-module giving sensibly proportionate distribution as long as the rating curve of the distributary at the point does not change.

---

[15] Panjab Eng. Congress, 1924, *Paper 89*, Paragraph 5, *et seq.*

It has also been shown mathematically, that an orifice semi-module discharges proportionally when the submergence of its zero point is three-tenths the designed supply depth.[16] However, in this case the two exponents, $\frac{5}{3}$ and $\frac{1}{2}$, are dissimilar, involving opposite curvature.[17] They are only tangential at a point, and away from it they diverge rapidly. Such an orifice is, therefore, "proportional" to a much more limited degree; but that objection is partly overcome by the device developed by Mr. Crump.[18]

Expansion of this mathematical treatment results in the conclusion that, for a flume the submergence of which is the fraction, h, of the supply depth, the proportionality, r, equals $\frac{0.9}{h}$, and for an orifice, r equals $\frac{0.3}{h}$. These formulas give the measure of the degree to which the performance of a semi-module may be made to approach that of a module by setting it deeper.

If the outlets of a length of distributary are fitted with modules, all the variation greater or less than the designed supply reaches the tail, since none of the outlets receives more or less than before. On the other hand, if all the outlets received proportional supplies, the percentage variations at the head and at the tail would be equal. Between these extremes, the use of semi-modules set with proportionality of less than 1.0 magnifies the percentage variation of supply from point to point down the channel; and the mathematical treatment referred to gives the measure of this magnification. The mathematical assumptions must not be overlooked, namely, that the variations are small, and that the outlets are infinite in number and of infinitesimal discharge. Let,

r = the proportionality of the outlets used.
S = the ratio of supply at the head of the reach to that at the tail.
V = the ratio of percentage variation from the designed supply at the head, to the percentage variation resulting at the tail.

Then,

$$V = S^{r-1} \quad \text{.........................} \quad (1)$$

Subject to the assumptions made, it is then possible to calculate and design a system with semi-modules for outlets and furcations of channels with a desired distribution not only of the designed supply, but also of variations from the designed supply.[19] For example, if it is necessary to be prepared for each distributary to admit, in an emergency, an excess of 2½% at the head, while up to 20% excess can be carried at the tails without danger, and it is desired to use orifice semi-modules set near bed level (proportionality = 0.3), it will suffice to fit flumes that are set for proportional distribution to tail outlets that receive one-twentieth of the head discharge.

PRACTICE OF GROUP DISTRIBUTION

If positive modules are used, it suffices to determine the proportion of tail outlets that must be fitted for proportional distribution, to form a sufficient safety valve. For want of a sufficiently satisfactory form of positive module, their use has nowhere yet become general. For some conditions such modules are very desirable, and even the nearest substitutes, are rather unsatisfactory. For example, in the Deccan, weed growth is apt to be so heavy that the supply level in a channel designed to run 3 ft. deep may rise by 3 ft. For other conditions, such modules are useless; as, for example, in inundation canals the supplies of which are not secured by river weirs, but depend on the natural rise and fall of the river. In such canals the best use possible must be made of the widely fluctuating supplies, and, therefore, they must have rather flexible distribution.

Proportional distribution has most adherents in the Panjab at the present time. This is probably in large part because designing is very simple and progress always takes the simpler steps first. It is found satisfactory that these measures effect great improvement on distribution by uncontrolled culvert outlets, and the limitations involved in the assumptions made to simplify theory are not realized. For example, the fluctuations of supply level due to silting cause departures from designed distribution which are greater than need be incurred. It is very easy, although illegal, for cultivators to steal quite a quantity of water by obstructing the distributary below their outlets.

Theoretical ideals being thus unrealizable, an intermediate policy is advocated as the best practicable course. This involves distribution, as nearly constant as possible, to the maximum number of outlets. It is effected by fitting the maximum number of outlets with orifice semi-modules set as deep as possible, confining proportional distribution to tail clusters, and using positive modules only where fluctuations of supply level are too great to allow of compromise.

This policy is naturally the subject of controversy in opposite directions with the advocates of the two ideal policies quoted. Positive moduling is likely to win for some conditions if and when types of modules are developed which compete with semi-modules in certain essentials. They must be cheap; simple and robust of construction and action; sufficiently accurate in discharge; susceptible of adjustment by the engineer, but not of undetected adjustment by the cultivator; they must work with water containing weeds and mud, and must not be deranged by flotsam and jetsam; they should require only a small minimum working head, and should have such range that they are easy to install and will cover actual fluctuations of supply level. It is also desirable that they show the discharge they are set for, and indicate (like the bubbling of a Kennedy outlet) when they are working. When such modules are produced, the field they can best cover can only be found in actual practice; for example, on a Panjab perennial canal the present tail clusters may still prove to be sufficient as safety valves. On the other hand, it may be necessary either to fit a few more outlets for proportional distribution, or retain a larger number with sub-proportional distribution.

For other conditions the final solution is likely to remain that of maintaining nearer proportional distribution, in spite of the realization that the practicable version of the theoretical ideal involves disadvantages to be avoided as far as possible. It is argued that, even on a Panjab perennial canal, fluctuations of supply are such that any approach to rigid distribution endangers the tails; where relatively rigid distribution has been used, this has been disproved for present conditions; and present conditions include much more variation of the supplies received than obtain as metering and moduling are extended. There is also a measure for more effective use of the tail safety valves to be applied.

If a distributary furcates into two minors, one large and the other small, both fitted for sub-proportional distribution, but with equal proportional tail clusters; and if the furcation into minors is also fitted with flumes for proportional distribution, the tail of the larger minor will experience much larger fluctuations than that of the smaller. A method has been shown[20] in which the proportionality of distribution between minors is adjusted so as to give equal fluctuations at both tails, enabling each safety valve to be fully used.

SURVEYS FOR SWIFT RIVER RESERVOIR OF THE BOSTON METROPOLITAN WATER SUPPLY[1]

By N. LeRoy Hammond,[2] M. Am. Soc. C. E.

With Discussion by Messrs. C. B. Breed, C. L. Hall, Frank C. Selinow, and N. LeRoy Hammond.

Synopsis

It is the purpose of this paper to outline, briefly, the methods pursued in the work of real estate and topographic surveys preparatory to the construction of the Swift River Reservoir.

The methods adopted are similar to those used on other large projects, with modifications to meet local conditions of valuation and time. On this work, the aerial survey has been used as a guide to the ground survey rather than in the final preparation of maps.

Introduction

The water-shed of the new Swift River Reservoir for the Metropolitan Water District of Boston, Mass., embraces an area of about 186 sq. miles. Of this, about 88 sq. miles will be required for reservoir purposes, such an area including land within and extending approximately ½ mile from the proposed reservoir. The area of operation involves practically all of the Towns of Enfield, Greenwich, and Prescott, Mass., and parts of at least seven other towns.

The Swift River is formed by three main branches (see Fig. 1), the East, Middle, and West Branches, so-called. The water-shed of the river is characterized by a series of high ridges running generally parallel in a northerly and southerly direction. The middle and upper part of the main valley is occupied by a number of rugged, mountain-like rocky hills which rise 300 to 500 ft. above the valley floor. The valley is sparsely settled, having had a population in 1920 of about 20 persons per sq. mile, who lived mainly in the small villages in the valleys of the principal streams. Small areas in the valley, however, were devoted to agricultural use, the remainder consisting for the most part of woodland varying from scrub growth to mature timber.

FIG. 1.—CO-ORDINATE AND SHEET LAYOUT FOR SWIFT RIVER RESERVOIR.

Work of surveying the large area involved was started in the late fall of 1926. The surveys involve two major divisions—that of detailed topography within the basin of the proposed reservoir, extending at least 10 ft. in elevation above any probable flow line, and that of real estate involving the determination of all holdings within the reservoir requirements. Miscellaneous studies have been carried on coincidentally with the topographic and real estate surveys.

TRIANGULATION

Control for all survey work has been obtained by a net of triangulation. The general terrain of the Swift River Valley was found to be ideal for a good system of quadrilateral network, except that considerable difficulty was experienced in the setting of stations so that they would be visible longitudinally along the axes of the valleys from quadrilateral to quadrilateral. Due to the fact that the hillsides are more or less uniform as to longitudinal slope, and, because of the occurrence of spasmodic growth of heavy timber, it was somewhat difficult to obtain open lines of visibility. Considerable care was exercised in the placement of stations in order that damage claims from the cutting of timber might be eliminated as far as practicable.

It was found that a considerable number of triangulation stations had been set in the valley or its environs by the former Harbor and Land Commission of the Commonwealth of Massachusetts and other governmental agencies. A few of these stations were in the secondary net used as a control of the Massachusetts Topographic Survey. In so far as it was practicable in developing a network of well-conditioned triangles, these stations were occupied and used in the general system adopted. The geographical positions of these early triangulation stations were published in 1912, by the Harbor and Land Commission in the atlas of the boundaries of the various towns of Massachusetts, and the citation of latitude and longitude lends an opportunity for a check on a system which could include some of the older triangulation points.

It is the thought of the writer that few engineers appreciate the quantity of accurate information and data available within relatively small areas for a check and tie-up of land surveys of all descriptions. Throughout the Commonwealth of Massachusetts there are many triangulation points of known geographical location, together with the positions of all town corners, of which careful descriptions supplemented by an actual survey sketch are given. A more general use of the data at hand would do much to correlate the many surveys which are constantly being made.

In the surveys of the Swift River Valley, the general network consisted of two chains of quadrilaterals covering two of the major valleys extending generally parallel in a northerly and southerly direction. At their upper and lower ends, the quadrilaterals were brought together in order that a proper check might be available for the entire system. In a few cases, polygons with an interior station were included in the system as well as a few simple triangles to make control accessible to certain districts. Common tripod signals, about 25 ft. high, were permanently erected on each of the stations of the system. The signals were constructed so as to permit setting the transit directly under the signal mast. Angles were measured by an engineer's transit graduated to minutes. Six repetitions of each angle were made and the error of closure of the figures of the network was generally kept considerably less than 8 sec. The triangulation network was laid out with the requirement that no angle should be less than 27° and with triangles as nearly equilateral as possible.

A base line about 1 mile in length was chained precisely by the slope method, using a standardized Chicago tape with spring balance. From the base line the system was developed to the major net of the triangulation. By utilizing the old existing triangulation points into the network of the system, with the published locations of these stations, it was possible to apply several checks to the new system. From the main network of triangulation, called the primary system, secondary triangulation stations were located as the needs of the detailed survey developed.

CO-ORDINATES

In order to facilitate the location of any point in the area, a plane system of co-ordinates was adopted with axes of reference sufficiently removed from the area so as to eliminate the possibility of minus co-ordinates, all co-ordinates being north and east of the locus of the system. The point of tangency to the surface of the earth of the plane of reference was assumed as an arbitrary point about midway of the area of operation. All vertical co-ordinates are parallel to a tangent to the meridian, 72° 18′ 00″, west of Greenwich, at its intersection with north latitude, 42° 22′ 30″, and all horizontal co-ordinates are parallel with a tangent to the parallel of north latitude, 42° 22′ 30″, at its intersection with the meridian, 72° 18′ 00″. Knowing the geographical position of triangulation points established in the town boundary surveys, it became possible to translate these positions to co-ordinates in the assumed plane of reference, thereby affording several checks on the entire system.[3] For all triangulation points, co-ordinates were carefully calculated and direct azimuth was computed and listed for the convenience of field parties. All surveys of every nature were run on a true azimuth derived from the triangulation system, and individual traverse stations were co-ordinated to the general system. As the triangulation points are established at relatively short distances apart, traverses on true azimuth were run into the area to be surveyed from either the primary or secondary triangulation legs. Practically all traverses have been run by use of the stadia, calculated and closed back to the triangulation system or other checked traverses.

TOPOGRAPHY

A precise line of levels based on the datum plane in use at the Wachusett Reservoir of the Metropolitan Water District was run into the valley and permanent bench-marks were established throughout the area of operation for the control of topographic and future construction data. Only a small part of the area to be surveyed was in open country, and topography was taken entirely by use of the transit and stadia board. Levels have been carried from the precise bench-marks by vertical angles and stadia board, all levels being checked back to either the precise bench-marks or to series of differential lines run by use of the dumpy level. The topographic survey covers about 28 000 acres and sufficient detail is taken for the plotting of contours at 5-ft. intervals, at a scale of 1 in. = 200 ft.

---

[3] See "Geodesy," by George L. Hosmer, M. Am. Soc. C. E., 1919, p. 175.

In view of the fact that real estate survey requirements covered an area of great extent, involving the legal status of a vast number of parcels, the topographic surveys were carried on independent of real estate, except that the traverses established have been used for both the topographic and real estate work. However, the topographic survey included the location of all possible lines of real estate occupation to facilitate the actual real estate survey. The customary features of topographic information have been located, such as highways, watercourses, buildings, and cultural development.

Real Estate

Under its Legislative Enabling Act, the Commission may purchase land or acquire it by right of eminent domain. To date (1931), the latter privilege has not been exercised and property has been acquired by title in fee. It is probable that ultimately a general taking line will be laid down accurately and all property within the area described thereby will be acquired. A considerable number of years elapsed in the preparation and final enactment of the Legislative Act creating the future Swift River Reservoir and most property owners within the area affected were cognizant of the need of their holdings, resulting in the early listing of much of the property for sale. Upon the listing of property its location was approximately determined by the field office, in order that need for its purchase might be determined. The property was then appraised by agents of the Commission, and steps were taken for its purchase.

Prior to the actual transfer of ownership, the title of the property was examined by the Legal Department, and if metes and bounds or acreage appeared obscure or inaccurate, surveys were requested of the Engineering Office. The largest percentage of the holdings in the valley was in either farm or woodland, more or less undeveloped, and it soon became evident that, in most cases, the survey of boundary lines and corners could be made by the stadia method to meet most requirements satisfactorily. It should be borne in mind that the major part of all surveys lies within a probable general taking line, and individual acquisitions will ultimately border other acquisitions, so that considerable economy in field work may be exercised by the proper use of the stadia method of survey. In the actual surveys, a rigid requirement was enforced in that at least two independent locations were required of each property corner where such corners are located as side shots from a main traverse and are not included in the traverse calculations. Such a method serves as a check in plotting.

Plots were made to a scale of 1 in. = 200 ft. All traverses are checked back to themselves or other checked traverses, lines being run on a true azimuth derived in the beginning from the triangulation net. As often happens in undeveloped country, such as that encountered on this work, it has been found that exact property lines are more or less obscure even to the knowledge of the owner and it becomes necessary to examine, carefully, deed and title of abutting owners in order that all property in the vicinity of the surveyed parcel may be satisfied.

Title examination by the Legal Department was not confined to properties under immediate option for acquisition. It embraced all property which might be required. A systematic search of all titles in one of the towns was inaugurated and practically completed within one year. Four copy sheets of title abstracts were reduced by photostatic process to one letter-size sheet and given to the Engineering Office for its use. Thus, the Office had the advantage of being able to keep up to date with the title work and considerable economy resulted in the ability to survey considerable tracts of land in a systematic manner, with the result that to date (1931) about 58 000 acres of real estate have been surveyed in anticipation of request for such survey, or in the ultimate taking of all property.

Together with the preparation of maps for the actual acquisition of real estate by deed, an analysis of the property was made by the Engineering Office; that is, a review of all lines was written, with its relation to the deed held by the owner, as well as to the deed held by the abutting owner. The writer has found that assistants acquire a much broader outlook on real estate survey requirements by being obliged actually to write out their analyses for review by the Legal Department. A suggested description for possible deed conveyance also accompanied the map of the property when it was returned. This requirement has the tendency to make certain that necessary bounds, lines of occupation, distances, etc., appear properly on the map before it is passed to the Legal Department. The requirement of map analysis of deeds, and suggested description appeared at first to be somewhat burdensome to an engineering force, but as such analyses would be required mentally in the process of a survey, the actual writing of the story soon became a comparatively simple matter. It was found extremely valuable not only in the training of the personnel to a proper real estate survey, but also in the placing on record of the reason for each bound, line of occupation, or map line, embodied in the final map.

Aerial Surveys

Fortunately, prior to any actual work of intensive survey in the Swift River Valley, a contract had been made for an aerial survey of that part of the valley covered by the proposed future operation. The contract called for the photographing of about 100 sq. miles of area and the delivery of so-called contact prints. Photography from the aircraft was at an elevation of about 12 000 ft. above sea level, resulting in contact prints of about 7 by 9 in., with an average scale of approximately 1 in. = 1 100 ft. The contract also provided for enlarged prints to a scale of 1 in. = 400 ft. Because of the natural topography of the Swift River Valley with its series of high ridges, the individual contact prints were of areas with elevations varying in many cases as much as 500 ft., or more. With the resultant camera distortion, it was found extremely difficult to determine a suitable control scale for reproduction to a scale of 1 in. = 400 ft.

A variety of scales existed between various points of the same print, due to the considerable differences in ground elevation, with resultant photographic distortion. It was decided that, except by the utilization of considerable ground survey, the enlarged prints were of little comparative value; therefore, few contact prints were enlarged. In fairness to this method of survey, it may be stated that by considerable study for the proper placing of ground control, ratios could have been deduced so that a reasonably accurate mosaic could have been developed. For the purpose to be served it appeared that the contact prints in themselves were sufficiently clear and capable of being pantographed as the ground survey developed a control for the needs of the work. The contact prints were in more or less constant use from the time of their receipt and were extremely valuable in many ways.

Value of Contact Prints.—An inspection of aerial contact prints indicates, by lines of occupation or by variation in timber growth, the possibility of proper location in the field. In the cases of three of the towns affected by the Swift River Reservoir such lines were pantographed to a skeleton map of the town. With these data on the map a perambulation of the town was made in company with its assessors to determine the approximate ownership of lands within its limits. Lines which had no significance as property lines were crossed out in the field and a somewhat crude map of property ownership within the town was developed. Such maps have been of considerable advantage to title examiners in the tracing of ownership titles. The maps were executed simply as an aid to an accurate ground survey of the area.

Considerable use was made of the contact prints in the location of difficult lines and corners. Many times a difference of a few years' growth of timber would not be apparent on the ground, but the line of demarcation was shown on the aerial photograph, and data were taken from the contact print indicating azimuth and distance for a field location of the desired lines or corners. The contact prints were useful during the process of checking the mapping of topographic detail, as any error in field work or of interpretation of notes was quite evident.

Cemeteries

Within the area needed for reservoir purposes were several cemeteries which required removal outside the reservoir limits. Each cemetery was surveyed, including a location of all monuments and markers, together with the exact location of the indication of all burials. Copies were made of inscriptions on all stones and so far as possible data were gathered as to actual lot ownership. A census of burials in the cemeteries indicated the existence of more than 5 000 interments.

A card index system was developed covering the data of each interment, together with information concerning lot ownership. In many cases the latter data are more or less obscure due to the absence of old town records; but as actual removals are made, public interest will make known much of the missing history of actual interments and of interested parties. To date (1931), four hundred removals have been made to lots outside the reservoir area, owned by parties at interest. No general work of removal has as yet been undertaken. A new cemetery is to be established by the Commission outside the reservoir area for the re-interment of remains to be moved. Such a cemetery has not yet been located.

Mapping

All record plots of topography and real estate were made to a scale of 1 in. = 200 ft. The entire area was laid out to a network of standard sheets with definite assignments of sheet numbers to areas included within set co-ordinates. The standard sheets have an inside border dimension of 24 by 36 in., with no overlapping of data to adjoining sheets. Original plots of topographical and real estate data were made on the same sheet, consisting of white paper mounted on cloth, standard titles with graphical scale having been printed on the sheets before delivery to the field office. The sheets are oriented with their margins parallel to the co-ordinate lines previously described. Convenient working co-ordinates were carefully laid down on the sheets and as triangulation and traverse stations were calculated with their proper co-ordinate positions, they may be easily plotted. Detailed data were plotted by means of a paper protracter with an arm, or by a drafting machine. As all data were taken on the true azimuth which corresponds to the vertical co-ordinate lines, the matter of plotting was extremely simple.

Two sets of tracings were developed from the record maps, one showing topographic features and the other, real estate holdings. These tracings were of the same size as the record map with no overlap of data, one to the other. Standard titles with graphical scale were printed on cut tracing cloth before use by the field office, thus making for uniformity in the finished result.

With the early assignment of sheet numbers to areas included within definite co-ordinate limits, it became easily possible to control for reference, the location of any data taken. Each triangulation station was given a number which corresponded to that of the record sheet on which it would occur, and all data taken in the field were correlated to their proper sheet numbers. Loose-leaf note-books were used and the data taken were grouped together to form books that had numbers similar to those of the record sheet on which the information might be found. This system simplified the matter of keeping in order the information secured. If a field party was assigned to a definite task, it could (by locating the sheet number of the area in which it was interested) immediately secure all available data taken previously in that particular area and could then reduce its own work to a minimum.

All real estate parcels were numbered first with the key number of the sheet on which the largest part of its area occurred and then with a second number that was one of consecutive numbers on each individual sheet. On an abutting sheet, a portion of the parcel occurring on that sheet took the same number as that on the sheet on which its largest area occurred. Thus, there was no duplication of parcel numbers in the entire area and the location of any parcel of land could be quickly determined if its sheet number had been assigned.

Distances on real estate maps were scaled from the original record map, except in the case of small or village areas where the field survey distance was entered. Areas for the most part were determined by planimeter, or were calculated by scaling from the record map. Each sheet had an absolute theoretical area included within its limit, and in the determination of individual areas it was made certain that the sum total of all areas equalled the theoretical area of the sheet.

PHOTOGRAPHY

All photographic work, including the developing and printing of photographs was executed by the field office. Photographs were of standard size (5 in. by 7 in.) and for record purposes they were mounted on white cloth. Photographs were made of all buildings or other objects about which information was desired for record of real estate value. Each cemetery lot occurring within the area subject to removal was photographed to make a record of monuments and markers in existence in each individual lot.

Photographs were numbered consecutively as taken, but, for purposes of identification, a small blackboard was placed in the view. On the board the name of the property owner and the date and number of the photograph were written in white chalk. The record sheet number on which the survey of the building appeared was also shown on the board, thus tying the location down to a comparatively small area. A small white or black arrow, depending on the ground color, was placed in front of the board in the direction of the north point as determined by a pocket compass. A small sketch was drawn in the lower left-hand corner of the negative, showing the position of the camera and objects in the photograph, with relation to highways or other general features in the vicinity of the objects photographed.

PERSONNEL

All the work of surveying and mapping, as far as the Swift River Valley is concerned, was undertaken from one field office with a personnel varying from a maximum of forty-five men to an existing field engineering force of twenty men. The work is being done by the Metropolitan District Water Supply Commission, with Headquarters Engineering Offices in Boston, Mass., all work being under the direction of Frank E. Winsor, M. Am. Soc. C. E., as Chief Engineer.

DISCUSSION

C. B. Breed,[4] M. Am. Soc. C. E.—This paper describes a surveying project unique in its performance, although quite common in its general aspects. It involves procuring a great deal of detail, the accuracy of which is well controlled where needed, yet "sketchy", where a low degree of precision is sufficient. It is a problem in surveying economics. In such problems good judgment based upon considerable experience is required in order that the survey-dollar may be reflected properly in the resulting data or plans. It is very easy to spend too much money on unimportant parts of the survey and too little on essentials. In fact, the opinion of well qualified surveyors may properly differ as to the most practical assembly of surveying methods to apply in order to reach a balanced economic result.

While the opinion of the speaker differs somewhat from that of the author in a few instances, it should be borne in mind that Mr. Hammond was on the site and that the speaker has not been on this project; the author has seen conditions at first hand while the speaker has viewed them through Mr. Hammond's lucid description of the conditions he encountered.

The control of the entire survey appears to have been logically laid out. It was properly joined with the triangulation stations established by the previous Massachusetts State Commissions. Mr. Hammond's comment that many valuable data of this kind are available and in usable form cannot be emphasized too forcefully. Many surveyors would gladly make use of such data, but, unfortunately, private projects too often have to be started before the surveying party has had time to connect it with the Government base of levels or triangulation control. In State work of the character described by Mr. Hammond, it is more readily done than in private projects, because more time is usually permitted for preliminaries.

Accuracy of Instrument Work.—It is somewhat surprising to learn that a 1′ transit was used in the triangulation system. The idea of using a 10″ transit may be abandoned because of its weight, but a 30″ or a 20″ transit of the same weight as a 1′ instrument may readily be obtained. By using a 20″ transit, the adopted precision could have been reached more quickly; or, with the same number of repetitions of angles, a higher precision could have been reached for the same cost.

It is so easy to obtain "closures" of much less than 8″ that it seems a pity that such a well-planned system as that described by the author, could not have been surveyed with greater precision. The time required for reconnaissance and signal building is the same in either case. The additional few minutes required to obtain the angle within 2 or 3″ is negligible. Had this been done, the results obviously would be of greater value to future surveys in that general district.

It seems a little unusual to measure the base lines with an ordinary steel tape and to determine and apply temperature corrections throughout the work, when an invar tape could have been used and the temperature corrections omitted. Of course, the invar tape is more brittle and requires more care in handling in rough country. It seems doubtful, however, whether lines measured by the ordinary tape as described would give a better base than could have been obtained by using the old State triangulation distances or by computing bases from the geographical position of those old State monuments which were properly joined with the system.

---

[4] Prof. of Railway and Highway Eng., Mass. Inst. Tech.; Cons. Engr., Boston, Mass.

The application of the plane co-ordinate system for the location of all points is especially adapted to the ready replacing of lost points in a district where so much cutting of timber and general change in immediate surface of the terrain is to be made.

Transit and Stadia Versus Plane-Table.—While the control of the topographical map by triangulation and by precise levels is excellent, the speaker questions the advisability of using transit and stadia for detail topography. In the open country the plane-table has distinct advantages over the stadia and transit methods. Even in wooded countries, the speaker prefers the plane-table for economy and for other reasons.

The number of points that have to be located is much smaller; the shape of the terrain ought always to be sketched while it is before the eyes, because no amount of experience in office plotting and in drawing contours based on many plotted points in the office can represent so faithfully the shape of the ground, as the work of a good topographer who sketches the contours in the field and governs their accuracy by the position and elevation of a few intelligently selected points; and, lastly, the cost is less for a given accuracy of plan.

The Cruising and Sketching Method.—In dense woods, such as those described by Mr. Hammond, the speaker has found that the following cruising and sketching method gives satisfactory results for much of the topographic work of the character he has had to produce. Stadia lines are run by plane-table and alidade through clearings in the woods at intervals of, say, 500 to 5 000 ft., preferably parallel to each other; and contours are sketched on either side of these cleared lines for a short distance into the dense woods. The topographer then "cruises" the country between these stadia lines by running compass lines (usually at right angles to the stadia lines) at, say, 100 to 300-ft. intervals. He starts from one stadia line with the elevation determined by stadia level and runs at right angles through the woods to the other line. He sketches contours on a small hand-sketching board as he goes, using a hand level or a clinometer for determining elevations and for checking these elevations at the other stadia line ahead. Then he returns on the next range to the first stadia line, obtaining all the topography over the route which he has "cruised".

Those data are transcribed directly on to the plane-table sheet which has been left on the first cleared stadia line. He then proceeds to the next pair of ranges, running south, say, on one and back north on the other, checking out at each time on his levels, on his distance, and on his position up and down on the stadia line as he reaches the clearing where that line is run. This method gives an independent control on all the topography. It provides a check on all the cruising work, and it is the most economical method of which the speaker knows for obtaining fairly accurate contours in heavily wooded districts. The transcription of the contours drawn on the sketching board on to the plane-table discloses any apparent error, which should be corrected immediately in the field.

Cemetery Surveys.—The survey of cemeteries also can be readily accomplished by the plane-table, using taped measurements, in the following economical manner. First, select a system of triangulation, the vertices of the triangles being the outer corners of stones marking cemetery lot corners. These triangles can be, say, 400 to 800 ft. on a side. Measure these distances with a tape. Plot them on the plane-table sheets by use of the beam compass and scale. Use these points for the control of the detailed survey to follow.

The plane-table is set up at the corner of one of these stone bounds and oriented by sighting on another triangulation point. Several other existing, easily recognized, monuments are then cut in. The plane-table is next taken to another triangulation point and these same points are cut in and thus located on the plan. This does not require sending a man to the monument for the sight.

An iron rod three times the size of an ordinary lining pin is driven in the ground at the plane-table station. This rod is driven through the tape ring. The tapeman measures the distance from this pin to the various lot corner markers and the plane-table cuts in the direction with the alidade. He then scales on each line the distance called off by the tapeman, draws the boundary lines, and records the lot, its serial number, and the family name. Two men are all that is needed in this field party. They can survey a great number of lots in a day in this manner. It is well not to extend the measurements from the plane-table beyond, say, 80 to 100 ft. Then, the plane-table should be moved to another point which has been located from the last point. At any time the plane tabler can cut in his postion from the many monuments which appear on his sheet, and thus check his position. In fact, it is to his advantage when he can cut in three or four characteristic monuments within his sheet limits.

The next step is to measure with the tape the four sides of each lot and the two diagonals. These are recorded to the nearest 0.1 ft. on the plane-table sheet, the scale of which is 1 in. = 20 ft.

Office Work.—On a rainy day the individual lots are plotted on large cards forming a card catalog. The upper half of the card is cross-sectioned and the lower part is in lines and columns. In the upper part the lot is plotted to the scale of 4 ft. to the inch, or 8 ft. to the inch. These are plotted from the four dimensions and the two diagonals which were recorded in the field. In the lower portion of the card the tabulation of names, dates of birth and death, etc., are recorded. These are copied from the cemetery records.

The card is then taken into the field, and at each individual lot the headstones, footstones, and monuments are located by tape measurements and ranges. Each grave is identified from the list of interments in the lower portion of the card and from the wording of markers, and if there are interments that cannot be found that are indicated in the list, or graves that appear on the lot which are not in the list, further investigation is made to determine who the the person is that is buried at that spot or whether or not there is any interment.

The result of this kind of a survey is a plan of the entire cemetery on the scale of 1 in. = 20 ft. which, of course, can be reduced to any desired scale. It shows all the roads, paths, lots, and the water system. This is supplemented by a card catalog plan of every individual lot that shows every physical thing upon it. It records each interment by a number in the tabulation and by an actual drawing of the shape of the lot on the upper portion of the card, each interment being given a number corresponding to the number in the tabulation.

The advantages of this method are: (1) It is controlled by the measured triangulation, and a detail of every lot is drawn while that lot is before one's eyes; (2) it requires only two men in the field party; (3) it is economical; and (4) it presents plenty of work for rainy weather as well as for fair days.

The Aerial Survey.—In the property line surveys for real estate plans, aerial maps (or contact prints) were used on the Swift River surveys for two appropriate purposes, namely (*a*), reconnoissance; and (*b*), filling in, or identifying, details.

These contact prints form a good check on the position of physical features located by the stadia and transit notes when they are plotted in the office, in that the finished map should (except for distortion due to difference in elevation) appear like the contact prints in so far as fence lines and the location of buildings, roads, and other details of flat topography, are concerned. Of course, they do not form any check on contour locations except that where a steep face of a ledge may occur or a brook is located the contact prints should give valuable data.

In aerial work of this kind, the speaker has found it advantageous to place cheese-cloth markers at points which he wanted to identify readily in the contact prints, where the object was one that probably would not show up well on the print. These places can readily be marked by 3-ft. strips of cheese-cloth laid at right angles over these points, or in the form of a circle around the points. The little white crosses or circles show up clearly in the photographs.

Identifying Property Lines.—The analysis of evidence of property lines is an excellent practice. In wood lots these should properly show the position of blazes marking property limits; and, where different blazed lines are encountered on the same general property line, the apparent age of the blazes should be determined by cutting into the trees and counting the annual rings, and these facts should be noted on the analysis so that the line adopted may be supported by the strongest evidence found.

While the edge of timber clearings, which usually show up clearly in contact prints, is some evidence of property lines, it should be supported by other evidence as a rule, because it is not uncommon to find that when timber has been cleared an encroachment on adjacent property has been carelessly made, for which damage may or may not have been adjusted.

As stated at the beginning of this discussion, the problem is one of surveying economics. The speaker has tried to keep in mind the cost of the surveys and to suggest such modifications, as, in his judgment, would give either better results for a given outlay or would have given as accurate and complete results for less money.

C. L. HALL,[5] M. AM. SOC. C. E. (by letter).—It is noted that Mr. Hammond adopted the equivalent of the Army grid system of co-ordinates for his control, yet retained true azimuths. The writer's experience with the use of a system of rectilinear co-ordinates for surveys of small areas has led him to believe that it is much simpler to use grid azimuth when rectilinear co-ordinates are available. In this system, the true azimuth of any line at the point of tangency of the plane of projection becomes the grid azimuth for all lines drawn parallel thereto everywhere on the map; and hence the angle which any straight line on the earth's surface makes with grid north is constant for the entire length of the line. It is very little trouble to calculate grid azimuths between points the rectilinear co-ordinates of which are known because the cosine of the angle between the line joining the two points, and grid north, can be determined at once by noting the proper relation between the differences of their x and y- co-ordinates, respectively.

No advantage appears to accrue from the use of true azimuths, except possibly that lines in legal documents can be more readily described in ordinary surveyor's language. However, no one expects exact accuracy in the azimuths of boundary lines. Admittedly, differences in true azimuth over an area 11 miles from east to west will not be great, but if no grid azimuth is established field surveyors will be unnecessarily annoyed whenever they run control traverses.

Under "Aerial Surveys," Mr. Hammond indicates that he could see no use in aerial photographs enlarged from 1:13 200 to 1:4 800. This agrees with the writer's experience. For general checking, an enlarged aerial photograph may sometimes be more convenient (although seldom more economical) than a pantographed enlargement; but as enlargement always reduces clarity, it will never be as satisfactory as the original print, in studying the country. If surveys are being made instrumentally on a scale of 1:2 400, neither an aerial photograph nor an enlargement thereof will appreciably reduce the cost of field topography, except as an aerial view permits better planning. The scale of the aerial view, thus used, is relatively unimportant.

FRANK C. SELLNOW,[6] ASSOC. M. SOC. C. E. (by letter).—Although technical literature is quite replete with the procedure that has been successfully followed in planning and constructing water supply and other major hydraulic undertakings, little seems to have been published on the methods of surveying, mapping, and acquiring the real estate of reservoir sites as these methods have tended to become standardized. Perhaps it has been thought that surveying is too old an art to require further exposition as applied to reservoir sites. That this is a mistake is evidenced by the fact that all too often in the past—through too great a subordination of this work to other seemingly more important features of the project—no well-considered program was mapped out, the data obtained were not collected with an economy of effort, and the results did not meet expectations or fulfill requirements.

---

[5] Lt.-Col., Corps of Engrs., U. S. A., Cincinnati, Ohio.

[6] Div. Engr., State Water Policy Comm., Newark, N. J.

Reservoir sites in the eastern part of the United States have many common characteristics. All, naturally, are surrounded by relief which will range from hills to mountains; the valleys are usually fertile land, cultivated, and of fairly high value, and there will be some utilities, both public and private. Community life will usually center in one or more villages in which, also, are occasionally found industries requiring large quantities of water. The upland will usually be wooded and, compared with the bottom-lands, of low value. The area within the taking line will seldom be less than 5 sq. miles, or more than 100 sq. miles, depending upon the gradient of the stream and the size of the development. With this similarity in the physical features, standardization of surveying and mapping methods, with such slight modifications as are necessary to meet local conditions, would seem to be invited.

Due, perhaps, to the low average value of the land, maps, if any exist, are almost invariably of low-grade accuracy, or are published on too small a scale to be of value in the design of water-works structures, relocation of utilities, or the acquisition of the real estate. The topographical maps of the United States Geological Survey, supplemented by reconnaissance, will usually suffice to determine the feasibility of the project, but before detailed plans can be made a topographic map, preferably to a scale of not less than 1 in. equals 200 ft., must be available. Enlargements of the topographical maps of the United States Geological Survey will only have the effect of accentuating the inaccuracies inherent in drafting these or any small scale maps and will not produce a map which will fulfill requirements.

Simultaneously with the topographical survey, or at least well in advance of the flooding of the reservoir, a cadastral survey must be made for the purpose of acquiring all the real estate. Fortunately, the locus approaches the ideal for carrying out both these surveys with a high order of accuracy and, at the same time, at very reasonable costs. The manner in which the Swift River Reservoir surveys were conducted demonstrates an orderly and efficient procedure for collecting the necessary data. It would be interesting and useful information if the cost of the Swift River Reservoir survey and the surveys of other reservoirs—classified, say, into triangulation, traverse, real estate, and topography—were published. On a unit of area basis, there should be no great variance in cost.

If the terrain is not too heavily wooded, it can be stated confidently that the control for both surveys can be established more economically by triangulation than by precise traverse. Considerable thought and study will have to be devoted to locating the triangulation stations to obtain intervisibility, to avoid excessive cutting, and to keep within a 30° angular limitation. In the reconnaissance, the use of an aerial map should be a very useful adjunct. To avoid the displacement or destruction of stations by utility relocations or construction activities, they should be located at least 50 ft. higher in elevation than the future flow line. They should be preserved by monumentation and properly referenced, so that their usefulness will be continued should it be found desirable in later years to increase the real estate holdings or to make improvements. The surest reference for the control system is to tie, by traverse or triangulation, the origin of the local system of plane co-ordinates to one or more of the control stations on the North American datum. This will have the advantage not only of perpetuating the survey, but of eliminating all astronomical observations, and making it possible to orient and locate properly the survey data on any Government or State maps.

In establishing the triangulation control for the Swift River Reservoir survey, the author was fortunate in that the township corners were marked and their geographical positions known. These geographical positions, transposed into rectangular co-ordinates, furnished, as stated in the paper, several checks to the new system. This condition of frequently located monuments, the geographical co-ordinates of which are known, will not ordinarily obtain in most of the Eastern States, and without these checks a greater refinement in the measurement of the angles would be required to secure the same accuracy. Two sets of pointings—each consisting of six measures of the angle and six measures of the explement, with an instrument graduated to 20″—would be the least number of angular measurements deemed necessary for this class of work.

Although the several steps in establishing the control and in making the cadastral and topographical surveys of reservoir sites may be performed in much the same way, the degree of required accuracy will depend upon valuations as between two reservoir sites or between different parts of the same reservoir. In general, the higher the valuations the greater the accuracy demanded. In any event, the standard adopted for the cadastral work will meet all the requirements of the topographical map. It is believed that the following specifications for accuracy for maps plotted to a scale not greater than 200 ft. to the inch, will meet the most exacting requirements, whether distances are to be mathematically reduced or scaled: (*a*) Triangulation, 1 part in 20 000; (*b*) traverses, the stations of which are to be used for locating property corners, or as the starting and closing points of stadia surveys, 1 part in 10 000; and (*c*) horizontal distances between well-defined points as located by stadia, to scale accurately within 3 ft.

Engineers, for the most part, now recognize that aerial photography will aid and supplement the ground survey of any large tracts. The author made commendable use of this comparatively new art, but it is questionable whether he availed himself of its full possibilities. The aerial survey made was uncontrolled. Control could have been furnished by the valuation maps of the Boston and Albany Railroad Company, providing they contain the required data; if not, then a moderate amount of ground control would have been necessary, the expense of which, it seems safe to state, would have been more than offset by the benefits. It is believed that controlled mosaics to a scale of 200 ft. to the inch, on sheets to correspond to the co-ordinate layout, could have been obtained at not more than four times the cost of the contact prints. Mosaics in this form would have obviated pantographing and furnished, by direct comparison, a check on all property surveys. As most aerial survey companies will guarantee an accuracy within 0.25% in distances of 5 000 ft., or more, topographical features within areas surrounded by natural monuments (such as river, roads, etc., located by ground method), could have been transferred to the line map with the assurance that their positions would have been at least within the limitations of the stadia method. Contours would have to be obtained by the usual field methods.

N. LeRoy Hammond,[7] M. Am. Soc. C. E. (by letter).—For surveys of the extent covered by the Swift River Reservoir Project, Professor Breed has well expressed the necessity of properly applying the yardstick to methods to be followed when he writes, "it is very easy to spend too much money on unimportant parts of the survey and too little on essentials."

Professor Breed correctly states that greater accuracy in triangulation could have been obtained by a 30″ or 20″ transit, rather than by the 1′ transit actually used. On this particular project, instruments were selected which would be satisfactory for all phases of the entire project, including all necessary surveys and construction layouts. Because of the numerous checks afforded by existing State triangulation points, it was decided that the 1′ transit for triangulation would give satisfactory results.

While distances were computed in the triangulation system from the geographical positions of the State monuments used, it was deemed necessary to have an independent base line measured, in order to make certain that no error had been made in the selection of the older points. Had entire dependence been placed on the base-line measurement, it is probably true that the use of an invar tape would have been better.

The writer is in complete agreement with Professor Breed as to the possible use of the plane-table in filling in topographic features, and he believes that much of the Swift River Reservoir work could have been done with economy by the plane-table about as described by him. The writer has completed many surveys by this method, but feels that the make-up of personnel has much to do with its economical application. It is to be regretted that more engineers are not properly acquainted with the plane-table. In one survey with which the writer was connected, the party had started its detail by ordinary stadia methods when it was changed to the plane-table. After a week, the party chief was convinced that better progress could be made by the previous stadia method, but after a month he and his party were completely converted to the plane-table method over the ordinary stadia methods for the particular problem in hand.

Colonel Hall has indicated that the use of the true azimuth in a system of plane co-ordinates would involve considerable work for adjustment from point to point. The writer's statement in his paper that all lines were run on a true azimuth was incorrect, as lines were actually run from the grid azimuth derived from the true azimuth at the origin of the grid system. Colonel Hall has very clearly stated the advantage of this system.

In his discussion Mr. Sellnow has shown a broad vision of the general problem of reservoir survey. He has emphasized the necessity of properly tying in the origin of the local system of plane co-ordinates in order that the entire system may be referenced at any time to future use and extended mapping. In the Swift River Reservoir work, tie was made by a citation of the geographical position of the origin of the system.

---

[7] Div. Engr., Metropolitan Dist. Water Supply Comm., Enfield, Mass.

If the control is well established with an accuracy of 1 part in 20 000, as cited by Mr. Sellnow, it appears to the writer that no hard-and-fast general rules can be fixed as to the accuracy to be secured in the details of the survey, but that value of real estate, capacity of reservoir basin, construction layout details, and other local factors influence largely the degree of precision which may be deemed necessary and sufficient for each survey, and that the engineer must decide upon his degree of precision as local conditions warrant, in order that the desired results may be secured with the greatest economy.

The aerial surveys of the Swift River Reservoir area were run in 1926, and it is probable that considerable advance has been made in this art since that time. The writer found variations as great as 25% in the scale of different portions of individual contact prints due to difference in elevation of ground surfaces and probably to a tilting of the camera by gusts of wind, etc. An effort was made to secure enlargements of contact prints to a scale of 1 in. equals 400 ft., but it was deemed more economical to make enlargements by means of a pantograph from the contact prints direct, and use the results as a basis of comparison with ground surveys. This decision may have been brought about by a lack of knowledge of proper methods to be adopted in enlarging contact prints.

While companies engaged in aerial photography may guarantee an accuracy, as stated by Mr. Sellnow, it appears to the writer that this guaranty must depend upon the ground control, and, in cases similar to the Swift River Reservoir area, when such ground control is secured, the use of the aerial survey has passed and necessary ground surveys have become well established. The writer, however, is still of the opinion that the aerial survey is a decided asset to the work of the ground survey and its expense is well justified in many ways.

RUN-OFF—RATIONAL RUN-OFF FORMULAS[1]

BY R. L. GREGORY[2] AND C. E. ARNOLD[3] ASSOCIATE MEMBERS, AM. SOC. C. E.

WITH DISCUSSION BY MESSRS. LEROY K. SHERMAN, FRANCIS BATES, JOHN W. RAYMOND, JR., REGINALD A. RYVES, G. S. TAPLEY, W. I. HICKS, CARL H. REEVES, JOHN M. KEMMERER, LEONARD L. LONGACRE, G. H. HICKOX, DONALD M. BAKER, ALBERT R. ARLEDGE, CLARENCE S. JARVIS, C. E. GRUNSKY, RALPH W. POWELL, MERRILL M. BERNARD, CHARLES H. LEE, AND R. L. GREGORY AND C. E. ARNOLD.

SYNOPSIS

A discussion of methods of estimating storm-water run-off, statements, conclusions and comparisons, weighing of errors, advantages and disadvantages, and suggestions for improvement, form an important part of this paper.

Logically, the paper is divided into two parts. Part I contains an analysis of the factors involved; it presents conclusions, and proposes changes in the present methods of estimating run-off. Part II contains a series of derivations, introducing and advocating new factors and formulas. This part of the paper also contains practical examples and suggestions for the guidance of the designer.

PART I.—ANALYSIS OF VARIABLE FACTORS

INTRODUCTION

Many engineers are engaged in the design of culverts, bridges, storm drains, dams, and various structures, in which the first, and probably the most difficult, problem encountered is that of estimating the maximum storm, or flood, water flow to be expected from a given drainage area.

Being indeterminate, the problem is made more difficult by lack of observation and the present uncertainties in available data for the determination of values for the many varying factors that contribute to flow. Individual judgment must always play a large part in selecting values for these factors, and, consequently, some variation in results may be expected, regardless of the method used.

---

[1] Published in April, 1931, *Proceedings*.

[3] Los Angeles, Calif.

Nevertheless, it should be the duty of all engineers engaged in the estimation of run-off, not only to strive for the more accurate determination of values for the various factors involved, but also for better methods of applying values when determined.

The profession owes much to the engineers who evolved the various empirical formulas, which were the natural fore-runners of the more recent, so-called, rational method. One purpose of this paper, however, is to show why the use of these empirical formulas is not now to be recommended.

The rational method recognizes the element of time in the computation of storm flow and, although there is much room for difference in assumptions, causing disagreement in results, it is considered by engineers to offer the most reasonable approach to accuracy. This method in some form is, therefore, rapidly supplanting the use of empirical formulas. The present users of the rational method may be placed in two main classes: First, those who follow the detail method as outlined subsequently; and second, those who attempt to arrive at a time of concentration for the water-shed either by a comparison with tests on areas of somewhat similar characteristics, or, by roughly estimating the average velocity of the main channel of flow.

The detail method is slow and tedious, and the writers believe it to be erroneous under the customary assumptions. On the other hand, in attempting to determine average velocities for the purpose of obtaining the time of concentration, and, finally, the intensity of rainfall, by either dividing a large water-shed into only a few parts, or, by comparing them with other areas of somewhat similar characteristics, results may be found to be no more accurate than those obtained by the empirical formulas.

There is no uniformity in the conception of methods for deriving the various factors involved in empirical formulas, and in assumptions made in the present use of the rational method. If a detail process had existed, which could have been used as a criterion of accuracy, the writers would have needed on much of their work, a rational formula for obtaining a reasonable result for a water-shed, without "tabling" the area in detail. Many times the engineer must know the probable maximum run-off at one or more points on a water-shed, as, for instance, in designing a bridge, culvert, or dam, or a section of drain with large tributary area. There are also many occasions for the use of such formulas for preliminary and comparative estimates when the engineer is not justified in taking the time and going to the expense of making a long, detailed calculation of the run-off. There should be a rational method of arriving at a close approximation of the run-off from a given area by a more direct use of the several factors involved. The writers, therefore, have made the following analysis, resulting in formulas which may be used for run-off computations. It is also hoped that the paper will present a clearer and more uniform conception of the rational method; and that the inadequacy of the empirical formulas for general run-off computations will be made evident.

It should be stated here that no attempt has been made to set up a "mill" into which the various factors could be thrown, a crank turned, and a perfect result obtained. The computation of run-off will always require the best judgment of experienced engineers, and the data in this paper are submitted only with the hope that their intelligent use may be a time-saver in guiding the judgment of the engineer to a rational result.

NOTATION

Throughout this work the writers have endeavored to concentrate on original analysis, using previously published information only when necessary for clarity. The reader, therefore, is assumed to have a certain familiarity with existing methods for computing run-off. A complete list of the notation introduced in Part II of this paper is arranged in Appendix I. The notation for Part I occurs in the body of the paper as the analysis progresses.

EMPIRICAL FORMULAS

Various empirical formulas for estimating storm flow have been presented from time to time, to the Engineering Profession, and not a few of the leading cities use one of these formulas in estimating storm flow. Many engineers also use one or more of the formulas for estimating, checking, and comparing with local data, the run-off for the larger flood-control projects.

Presentation of the best known formulas by Metcalf and Eddy includes a clear account of their derivation, as well as a comparison of results obtained by their application. A wide difference in results is shown,[4] but this is not surprising when it is noted that no one formula, in the process of its derivation, includes all the varying factors contributing to the result sought.

It is not necessary to dwell at length upon these formulas, but it should be interesting to observe that, because of three considerations, the very nature of their construction precludes any possibility of allowing for the difference in flow, on areas of the same acreage and slope of the main channel of flow. These considerations are:

(1) Shape of area both as to external boundary and internal arrangement of drainage courses leading to the point of concentration;
(2) Condition and shape of the main channel of flow; and
(3) In addition to Considerations (1) and (2), the initial or inlet time cannot be allowed to vary in the empirical formulas, due to their construction.

A better conception of the effect of these three considerations, and others, is given subsequently in this paper. (See, "Inadequacy of Empirical Formulas".)

THE RATIONAL METHOD

The Fundamental Relation.—The relation between run-off and rainfall is, of course, correctly stated by the expression,

$$Q = C\,i\,A \qquad (1)$$

in which, Q, C, i, and A are as defined in Appendix I.

Attempts by engineers to solve this equation have evolved the so-called rational method. This method is based on the assumption that the maximum rate of run-off from any water-shed for a given rainfall intensity occurs when all parts of the area are contributing. To fulfill this condition, it follows that the rain must continue a length of time equal to, or exceeding, the time it takes water to travel from the most remote portion of the water-shed to its outlet. This is known as the time of concentration for the water-shed.

---

[4] "American Sewerage Practice," by Metcalf and Eddy, Vol. I, First Edition, p. 235.

Through the study of rainfall records, certain relations have been found to exist between intensity and time. It has been generally shown that a smaller average intensity may be expected for a longer period of time than for a short one. Probably the most common form of this relation in use for estimating run-off is,

$$i = \frac{K}{t^e} \qquad \qquad (2)$$

in which, K is a constant, and i is the expected average intensity for the time period, t.

Equation (1) is, therefore, more a statement of a fundamental relation than a formula. The factor, i, represents not merely a constant to be readily obtained, but depends for its value on the time of concentration of the water-shed, which, in turn, is determined by the average velocity of the water in traveling from the most remote section of the area to its outlet. This velocity is necessarily a function not only of the slope, shape, and condition, of the channel through which the water must run in traversing the water-shed, but also of the quantity of water itself, which varies due to the shape of the area and its manner of concentration.

Rainfall Curves.—In this paper the reader is assumed to be familiar with the general methods used in making rainfall curves. Selection of the proper curve is controlled not only by the economic features of the particular problem, but also by the locality of the water-shed. This part of run-off study, however, is not intangible, nor indeterminate, since the curves may be made from actual rainfall records. Many engineers avail themselves of the valuable records kept by the United States Weather Bureau in the particular section in which their problems occur.

Although the rainfall curves, as used, are based on tangible rainfall records, there is much room for the play of individual judgment in their making. While it is recognized that accurate records may be had for a definite period of years, it is also true that for another equal period of years, even in the same locality, the intensities for similar time periods may differ widely. Two engineers, working separately on the same rainfall records for a given period of years, may draw different types of curves, since it is difficult to determine whether a given point from observed data belongs on the curve representing the values for a certain expected frequency, or on a curve of a different frequency. Wide differences in the types of rainfall curves in use may be attributed to this latitude afforded the judgment.

Use of Rainfall Curve.—More important to this work is the intelligent use of the rainfall curve, which requires a knowledge of its make-up. It will be assumed herein that the ordinate of the curve represents the average rainfall intensity, i, expressed in inches per hour, that may be expected to last for the corresponding time, t, represented by the abscissa; or, stating it in another way, a water-shed with a time of concentration, t, may be expected to receive a rainfall with an average intensity, for the entire time, of i in. per hour.

Thus far, no mention has been made of how that part of the storm, which is expected to last for the time, t, is supposed to conduct itself. It may have an average intensity of i in. per hour, yet begin intensely and end lightly;

it may be intense in the middle of the time period and light at either end; or, it may begin lightly and end intensely.

In their study of rainfall records, the writers and others have found that an individual storm may begin or end in any manner, no definite general tendency as regards the order of greatest intensity having been observed.

The rainfall curves generally in use (including the construction of the various expected frequency periods, as 10, 15, 25, etc., years), are built on the basis of an average intensity for a given period, such intensity being determined from records of storms of various types as regards the relative intensity within a given time period. It is clear, therefore, that because a curve may have the form of Equation (2), there is no reason to assume that an individual storm will follow the law of this curve. In using curves so constructed the type of storm for a given time of concentration should be considered as independent of the law of the curves. To construct curves, the use of which is to imply that the type of storm to be expected for a given time of concentration is one whose variation in intensity for that time follows a definite law, would require the selection of data for the various time intervals from storms the rates of precipitation of which actually followed the particular law. The probable frequency periods would depend necessarily on the type of storm selected. This would be impracticable; and it would seem that the method now followed in making curves offers a rational attack, since the type of storm actually used approaches one of uniform intensity for the time of concentration.

This conception should be concurred in by those who pursue the detail process of the rational method in storm drain estimates, in which it is the evident intention to assume that the intensity is uniform over the entire watershed throughout the time of concentration. Such assumption, no doubt, would conform to that of C. E. Ramser, M. Am. Soc. C. E., of the U. S. Bureau of Public Roads, who states;[5]

> "The maximum rate of run-off, therefore, would result from a rainfall of maximum uniform intensity, continuing for a time equal to or exceeding the time of concentration."

The assumption of a uniform, or constant, intensity for a given time of concentration, affording the most feasible means of building rainfall curves to forecast the probable intensities and frequencies of storms, does not, of course, preclude the possible occurrence of precipitation varying in intensity within a given period of time; but a storm, following any definite law (in regard to the relative intensity within the time period) other than that of the average storm used in constructing the rainfall curves, may be expected to have a different frequency of occurrence. Hence, the 10-year, 15-year, 25-year, etc., frequency periods of the curves, as ordinarily constructed, cannot properly be used for forecasting storms of varying types.

The Detail Method.—In solving by the detail method, it is first necessary to determine the time it takes the water to flow from the most remote portion of the first small area, or nucleus, to its point of inlet to the main channel of flow. For this time the intensity, *i*, is determined from the rainfall curve in use, the value, Q, is calculated from Equation (1) and its time of flow to the next inlet point is determined. The time of concentration for the total area contributing at or above this second inlet point equals the concentration time for the first area plus the time of flow in the drain to the second inlet point. The rate of run-off, Q, is then calculated for the second inlet point, using the new time which gives a decreased intensity for the entire area contributing at, or above, the second inlet point, etc., at all inlet points until the entire water-shed is traversed.

---

[5] "Run-Off from Small Agricultural Areas," reprinted from *Journal of Agricultural Research,* Vol. 34, No. 9, p. 799.

Merely for the purpose of illustrating the use of the rainfall curve as generally practiced in the detail method, a simple water-shed is chosen. In Table 1 the points enclosed with circles represent inlet points on the main drainage channel, which is designated by the heavy line.

Let the total areas contributing water above the successive inlet points equal A_1, A_2, A_3, etc.; times of concentration, t_1, t_2, t_3, etc.; and corresponding average intensities, i_1, i_2, i_3, etc., respectively.

Let the individual areas contributing water to the successive inlet points be represented by a_1, a_2, a_3, etc. (shown on left of Table 1). Then, let i'_1, i'_2, i'_3, etc., equal the average intensity of rainfall on the areas a_1, a_2, a_3, etc., at the respective times, t'_1, t'_2, t'_3, etc. For this simple water-shed it is assumed that the time of concentration of the individual areas is approximately equal to the differences in time between inlet points on the main line, or, that the intensities, i'_1, i'_2, i'_3, etc., are due to the time periods, 0 to t_1, t_1 to t_2, t_2 to t_3, etc., respectively.

Considering Area A_n, Table 1, and following strictly the assumption of the rational method, that the maximum flow occurs when the storm lasts as long, or longer, than the time required for the water to travel from the most remote portion of the water-shed to its outlet, enabling all parts of the area to contribute simultaneously, then, the run-off from Area a_1, produced by Intensity i'_1, occurring at Time t'_1 will reach the outlet when Area a_n is contributing, due to Intensity i'_n falling at Time t'_n.

Likewise, the run-offs from Areas a_2, a_3, etc., produced by Intensities i'_2, i'_3, etc., occurring at Times t'_2, t'_3, etc., respectively, will reach the outlet when Area a_n is contributing, due to Intensity i'_n falling at Time t'_n. The total discharge at the outlet of Area A_n will equal the sum of the discharges from the individual areas composing the water-shed.

Now, solely for the purpose of illustrating the present use of the rainfall curve in the detail method, it will be assumed that the run-off coefficient is constant throughout, say, equal to one. Any form of Equation (2) may be selected. For example, let $e = 0.5$ and (when t is expressed in seconds) let $K = 120$. Values of average rainfall intensities, corresponding to successive abscissas of time, may be determined and plotted as ordinates in Fig. 1.

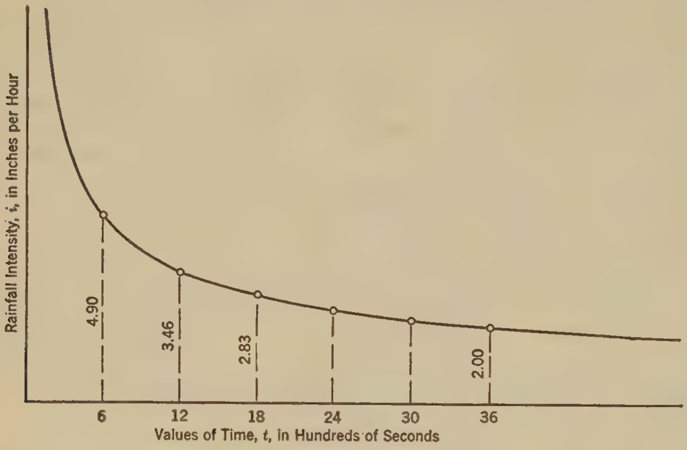

Fig. 1.—Illustrative Curve of Rainfall Intensities, $i = \frac{120}{t^{0.5} \text{ sec.}}$

Under the foregoing assumptions, the water-shed, A_n, is expected to receive an average intensity of 2 in. per hour for the time of 60 min. If this general detail method is followed, the time, 60 min., is determined by velocities, produced by the use of the intensities, 4.90, 3.46, 2.83, ... 2.0, for the areas, A_1, A_2, A_3, ... A_n, respectively.

Now, if the storm is assumed to have a uniform intensity for the period of time, t_n then, $i_1 = i_2 = i_3, \ldots = i_n$, and the velocities that produce the time, t_n, in the computations, will be the result of a uniform, or constant, intensity for the time of the water-shed.

Thus, although it is the evident intention to assume a uniform intensity over the entire area throughout the time of concentration, the process followed in the detail method automatically assumes the equivalent of a variable intensity during the period.

The particular type of storm thus automatically assumed, not only depends on the physical characteristics, and the shape and manner of concentration of the water-shed, but also on the type of rainfall curve in use. When the area is shaped so that the time of concentration increases proportionately with the contributing area, the type of storm automatically assumed follows the law of the curve in use.

Assume, for the purpose of illustration, a rainfall curve of the type,

$$i = \frac{K}{t^{0.5}} \qquad \text{(3)}$$

The average value of the ordinate, i, may be found as follows: When $y = f(x)$, or $i = f(t)$, the expression for the area bounded by the curve, the outer ordinate, and the co-ordinate lines, is $\int f(x)\,dx = \int K\,t^{-0.5}\,dt = \frac{K\,t^{0.5}}{0.5}$ $= 2\,K\,t^{0.5}$. Then, $2\,K\,t^{0.5}$ divided by the abscissa, t, $= \frac{2\,K\,t^{0.5}}{t} = \frac{2\,K}{t^{0.5}}$. Therefore, the average ordinate equals twice the end ordinate.

If, for a period of 60 min. on the water-shed, A_n, the storm had an average intensity of 2 in. per hour and followed the law of the curve, the intensity at the lower end of the area would be one-half the average, or, 1 in. per hour, while the intensity at the upper end would be infinite. Likewise, for the intensities of the areas, A_1, A_2, A_3, etc., the upper end would be infinite and the lower end, one-half the average (see Table 1).

The intensity for 60 min. equals $R_1 = \frac{K'}{3\,600^{\frac{1}{2}}} = 1$, and therefore, $K' = \sqrt{3\,600} = 60$. Substituting this value of K in Equation (2) and letting $e = 0.5$ as in Fig. 1; then,

$$i = \frac{60}{t^{0.5}} \qquad \text{(4)}$$

The average intensities (see Column (1) Table 1) for the individual areas are as follows:

For a_1,

$$\frac{2\,K'}{\sqrt{t_1}} = 4.90$$

For a_2,

$$\frac{\left(2\,K'\,t_2^{\frac{1}{2}} - 2\,K'\,t_1^{\frac{1}{2}}\right)}{(t_2 - t_1)} = 2.03$$

For a_3,

$$\frac{\left(2\,K'\,t_3^{\frac{1}{2}} - 2\,K'\,t_2^{\frac{1}{2}}\right)}{(t_3 - t_2)} = 1.56$$

and, for $A_n - (a_1 + a_2 + a_3)$,

$$\frac{\left(2\,K'\,t_n^{\frac{1}{2}} - 2\,K'\,t_3^{\frac{1}{2}}\right)}{(t_n - t_3)} = 1.17$$

Assume any values for the individual areas in Table 1 that will vary directly as the time, such as $a_1 = 100$, $a_2 = 100$, $a_3 = 100$, and $A_n - (a_1 + a_2 + a_3) = 300$ acres.

In Equation (1) let $C = 1$; then, the "Q-collecting" at the outlet of the water-shed would be as shown in Columns (2) and (3) of Table 2, with proper values of i and a substituted for each successive case. The average intensity would be $\frac{1\,200}{600} = 2$ in. per hour, which is the value used in the detail method. However, this process will produce the same time of concentration as the detail method, when and only when the area varies directly with the time.

When the area increases at a faster rate than time, the results are as illustrated in Columns (4) and (5) of Table 2. In this case, 1 900 acres × 2.00 in. per hour = 3 800 cu. ft. per sec., which is greater than the rate of run-off obtained by assuming that the storm obeyed the law expressed by the curve in use. Similarly, (Columns (6) and (7)), 200 acres × 2.00 in. per hour = 400 cu. ft. per sec., which is less than the rate of run-off obtained by assuming that the storm obeyed the law expressed by Equation (3).

TABLE 2.—RATES OF RUN-OFF, Q, FOR THREE TYPES OF WATER-SHED

Total......	600	1 200	1 900	3 049	200	661.7

Conclusions.—The foregoing observations lead to four major conclusions as follows:

1.—For a constant value of the run-off coefficient, and for the special type of water-shed assumed in Table 1, three facts are noted:

(*a*) When the time of concentration increases proportionately with the contributing area, the type of storm assumed follows the law of the rainfall curve in use.

(*b*) When the area increases at a faster rate than the time, the run-off obtained by the detail method is greater than that obtained when the type of storm is assumed to follow the law of the curve in use.

(*c*) When the area increases at a slower rate than the time of concentration, the run-off, Q, obtained by the detail method is less than that obtained when the type of storm is assumed to follow the law of the curve in use.

2.—In all cases, the detail method automatically assumes the equivalent of a storm of varying intensity, causing a smaller time of concentration because of a greater average velocity of flow (and, consequently, a greater value of Q) than would be obtained by assuming a storm of uniform (or constant) intensity for the time of the water-shed. The use of the rainfall curve is, therefore, inconsistent with its making, in that while the curve represents a certain period of expected frequency based on types of storms occurring in any variety of ways (averaging in effect a uniform intensity for a given period of time), it is really used to accommodate a system of tabling which automatically assumes a different type of storm for every type of rainfall curve and water-shed.

3.—Consider a storm that varies in intensity within the time of concentration, but is evenly distributed over the entire area at any moment. If the run-off coefficient is constant throughout the water-shed, the summation of discharges from the individual areas is the same as that due to a rainfall with a uniform rate of precipitation (equal to the average of the preceding rates) over the water-shed for the time period, when (and only when) the contributing area increases proportionately with the time.

4.—It is apparent, therefore, that neither the assumption of a uniform intensity over the water-shed for the time of concentration, nor its approach through the medium of the detail method, affords, in all cases, the absolute maximum run-off.

Statement.—It is manifestly the intention of those who use the detail rational method to assume that the expected storm is one of uniform intensity over the entire area throughout the time of concentration. The afore-mentioned inconsistency, affording the variable factor of safety, is due to the use of velocities that do not obtain under the assumption. Practically, however, this factor of safety is not of major importance, being usually only a small percentage. Practical visualization of its probable magnitude may be had from a comparison of the values of the factor, P, in Table 3 with those in Table 4, raised to the exponent indicated in Equations (28) and (29), given subsequently. The values shown in Table 3 are based on the assumption that the type of storm is one of uniform intensity over the area throughout the time of concentration; while those in Table 4 resulted from the use of the rainfall curve, of the type, $i = \frac{K}{t^{0.5}}$, as ordinarily practiced in the detail rational method. It should be mentioned that this factor of safety is varied somewhat by the type of rainfall curve; it may be somewhat greater for a given water-shed, for instance, when e in Equation (2) is 0.7 than when e is 0.5 as in Equation (3).

In order to arrive at a greater run-off than that rendered by the assumption of a uniform intensity for the area throughout the time of concentration, it would be necessary to assume a different manner of variation in intensity, within the period, for every water-shed. The peak, or rather the peaks, of the storm, for the period of concentration, would then be so arranged that the contributions from the individual areas composing the water-shed might render the greater run-off. Intensities are relative, however, and there is no limiting peak, either in height or duration. There is, then, no absolute maximum for a given water-shed; and, although it is possible to arrive at a greater run-off than that to be expected from the rational assumption, the impracticability of predicting the probable frequency of occurrence of storms particularly selected for every type of water-shed, the difficulty in determining the effect on the run-off coefficient, and the variability of the time of concentration, due to all physical characteristics of a water-shed and changes in intensity, complicate the problem to a measure almost beyond practical solution.

Assuming a uniform intensity for the entire area throughout the time of concentration enables the engineer to forecast with reasonable accuracy the probable frequency of this average storm. The solution of the run-off problem by means of rainfall curves, showing the relation between time and intensity for various periods of expected frequency, therefore, may be adopted as the standard basis for economical design. It may reasonably be considered that the possible arrangement of intensities, within the time of concentration, to render a greater run-off, constitutes a very rare occurrence, which (in special cases only) may be taken care of by a special factor of safety.

Factor C, The Run-Off Coefficient.—Among the afore-mentioned uncertainties in available data for the estimation of storm flow, the run-off coefficient, Factor C, probably offers the widest range of values for water-sheds with similar characteristics calculated to affect this factor. Much has been written concerning this factor, and it is not here considered necessary to review all the many characteristics of a water-shed that determine its value. The writers, however, do wish to stress one main difference in assumptions for the variation in the value of the run-off coefficient as made by those who use the rational method; that is, C is assumed to vary in one of the following three ways (the type of territory as regards physical characteristics, irregularities of surface, etc., being the same):

(1) C increases as the time increases.
(2) C remains constant as the time increases.
(3) C decreases as the time increases.

Although many examples could be shown, it should suffice, for the purpose of comparison, to give one typical example of each of these assumptions.

Assumption (1) is exemplified by Table 5 which was used in design by the City of Hamilton, Ont., Canada.

TABLE 5.—RUN-OFF COEFFICIENTS USED FOR DESIGN PURPOSES IN HAMILTON, ONTARIO, CANADA

Duration of rainfall, in minutes	Run-Off Coefficients		
	Pervious surface	Outlying district	Central business
5	0.00	0.50	0.75
10	0.05	0.60	0.80
15	0.10	0.75	0.85
20	0.15	0.80	0.90
25	0.20	0.825	0.95
30	0.25	0.85	0.95
35	0.30	0.865	0.95
40	0.35	0.883	0.95
45	0.40	0.90	0.95
50	0.45	0.917	0.95
55	0.50	0.93	0.95
60	0.55	0.95	1.00

Table 6 used by the City of Washington, D. C., may serve as an example of Assumption (2).

TABLE 6.—RUN-OFF COEFFICIENTS USED FOR DESIGN PURPOSES IN WASHINGTON, D. C.

Characteristics	Constant run-off coefficient
Extreme suburban areas with 20 to 40% parking and widely detached houses...	0.35
Suburban areas with widely detached houses..	0.45
Suburban areas with widely detached houses..	0.55
Areas with 50% attached and 50% detached houses....................................	0.65
Areas closely built up..	0.75
Business areas..	0.85

An example to illustrate Assumption (3) has been given[6] by C. E. Grunsky, Past-President, Am. Soc. C. E., and need not be reproduced for present purposes. It should be evident to the reader, without further elaboration, that these assumptions for the value of the run-off coefficient for use in the fundamental relation, $Q = C\,i\,A$ (or its equivalent in other letter designations), may lead to widely different run-off quantities for a given water-shed, no matter how carefully and how accurately the calculations may be carried out for a given case.

On account of the many varying conditions and characteristics of water-sheds, accurate measurement of the run-off coefficient is very difficult to accomplish. Much of the available experimental information is of little value, and, no doubt, improper analysis of some of the more valuable results is often made. The writers at this point wish to urge a more unified effort on the part of the profession not only toward a thorough analysis of present available data, but also future experimentation along lines following a preconceived plan.

---

[6] *Transactions*, Am. Soc. C. E., Vol. LXV (1909), p. 325.

Pursuant to this thought, the writers offer the following analysis with the hope that the conclusions drawn will be helpful in future consideration of Factor *C*.

Among those who have contributed to the information on run-off, probably no one man has done more and better work than the late Emil Kuichling, M. Am. Soc. C. E. Many of those who base their computations on Assumption (1), probably have been guided by the following five conclusions drawn by Mr. Kuichling[7]:

5.—"The percentage of the rainfall discharged from any given drainage area is nearly constant for all rains of considerable intensity, and lasting equal periods of time * * *.

6.—"The said percentage varies directly with the urban development of the district; or, in other words, with the amount of impervious surface thereon * * *.

7.—"The said percentage increases rapidly, and directly or uniformly, with the duration of the maximum intensity of the rainfall, until a period is reached which is equal to the time required for the concentration of the drainage waters from the entire tributary area at the point of observation; but if the rainfall continues at the same intensity for a longer period, the said percentage will continue to increase for the additional interval of time at a much smaller rate than previously. This circumstance is manifestly attributable to the fact that the permeable surface is gradually becoming saturated and is beginning to shed some of the water falling upon it; or, in other words, the proportion of impervious surface slowly increases with the duration of the rainfall.

8.—"The said percentage becomes larger when a moderate rain has immediately preceded a heavy shower, thereby partially saturating the permeable territory and correspondingly increasing the extent of impervious surface.

9.—"The sewer discharge varies promptly with all appreciable fluctuations in the intensity of the rainfall, * * *."

There can be no doubt as to the correctness of Conclusions (6), (7), (8), and (9), but it is probable that some users of the rational method have misconstrued Conclusion (5) (and perhaps Conclusion (7)), or taken it too literally, in forming conclusions regarding the variation of the run-off coefficient.

For any water-shed not completely saturated from the beginning, and having constant physical characteristics throughout which are calculated to affect the run-off coefficient, the following conclusions will hold:

10.—Because of an increasing wetness (causing a higher percentage of imperviousness) the run-off coefficient for the successive individual areas composing the water-shed, increases with the time.

11.—For the intensity decreasing with the time, the run-off coefficient for the successive individual areas composing the water-shed, will decrease with the time.

12.—For all rainfalls of considerable uniform intensity on any given water-shed (the previous degree of saturation and physical characteristics remaining constant for the separate precipitations), the run-off coefficient for a rain of given intensity will be higher than that for one of less intensity, and conversely.

Referring again to Table 1, assume a simple water-shed with constant physical characteristics throughout. Let the individual areas contributing water to the successive inlet points be represented by a_1, a_2, a_3, etc. (see Table 1). Let i'_1, i'_2, i'_3, etc., equal the average intensities falling on the areas, a_1, a_2, a_3, etc., at the respective times, t'_1, t'_2, t'_3, etc. Let C'_1, C'_2, C'_3, etc., represent the respective run-off coefficients.

---

[7] *Transactions*, Am. Soc. C. E., Vol. XX (1889), p. 37.

Let the total areas contributing water above the successive inlet points equal A_1, A_2, A_3, etc. Let C_1, C_2, C_3, etc., equal run-off coefficients; t_1, t_2, t_3, etc., equal successive times of concentration; and i_1, i_2, i_3, etc., equal corresponding average intensities for A_1, A_2, A_3, etc., respectively.

Let r = rate of retention, in cubic feet per second per acre. It should be understood that retention represents that proportion of the falling water which does not run off because of evaporation, absorption, and storage, or,

$$r = i - C\,i = i\,(1 - C) \qquad (5)$$

Hence, let the average rates of retention for the areas: a_1, a_2, a_3, ... a_n = r'_1, r'_2, r'_3, ... r'_n, respectively; and for A_1, A_2, A_3, ... A_n = r_1, r_2, r_3, ... r_n, respectively.

Conclusion (10) may be best illustrated by assuming a constant intensity, i, for any water-shed, as A_n. Then $(ia_1 - r'_1a_1)$, $(ia_2 - r'_2a_2)$, $(ia_3 - r'_3a_3)$, etc., represent run-off quantities, in cubic feet per second, for the areas, a_1, a_2, a_3, etc. From Equation (1), $Q = C\,i\,a$, or,

$$Q'_1 = C'_1\,i\,a_1;\; Q'_2 = C'_2\,i\,a_2;\; Q'_3 = C'_3\,i\,a_3;\; \ldots Q'_n = C'_n\,i\,a_n \qquad (6)$$

Therefore, equating, $C'_1\,i\,a_1 = i\,a_1 - r'_1\,a_1 \ldots C'_n\,i\,a_n = i\,a_n - r'_n\,a_n$, or,

$$C'_1 = 1 - \frac{r'_1}{i} \;\ldots\; C'_n = 1 - \frac{r'_n}{i} \qquad (7)$$

Likewise, it may be inferred that, considering the areas, A_1, A_2, A_3, ... A_n,

$$C_1 = 1 - \frac{r_1}{i} \;\ldots\; C_n = 1 - \frac{r_n}{i} \qquad (8)$$

Consider the water-shed, A_n, and follow the assumption of the rational method that the maximum flow occurs when the storm lasts as long as, or longer than, the time required for the water to travel from the most remote part of the water-shed to its outlet. This would enable all parts of the water-shed to contribute simultaneously; that is, run-off from Area a_1, produced by Intensity i, occurring at Time t'_1, will reach the outlet when Area a_n is contributing, due to Intensity i, falling at Time t'_n.

Likewise, the run-offs from Area a_2, a_3, etc., occurring at Times t'_2, t'_3, etc., respectively, will reach the outlet when Area a_n is contributing, due to Intensity i, falling at Time t'_n.

The rainfall that produced the run-offs from a_1, a_2, a_3, etc., lasted for the time, t'_n; but at the time run-off occurred the rain had lasted for a time, t'_1, on Area a_1, t'_2 on Area a_2, t'_3 on Area a_3, etc.

But, $t'_1 < t'_2 < t'_3, \ldots < t'_n$, and unless the water-shed was completely saturated before the rain occurred, $r'_1 > r'_2 > r'_3 \ldots > r'_n$. Therefore, $C'_1 < C'_2 < C'_3, \ldots < C'_n$, and the same process of reasoning would show that $C_1 < C_2 < C_3 \ldots < C_n$. It should be conceded, therefore, that Conclusion (10) is correct.

Conclusion (11) as applied to the rational method may be best illustrated by assuming a constant rate of retention for the individual areas composing any water-shed, such as A_n.

Then, the logic in the case of Conclusion (10) may be applied to Conclusion (11), substituting i' for i and r for r'. The result will be similar to Equation (8),

$$C_1 = 1 - \frac{r}{i_1}; \;\ldots\; C_n = 1 - \frac{r}{i_n} \ldots\ldots\ldots\ldots\ldots\ldots (9)$$

By inspection, it may be seen that, when $i'_1 > i'_2 > i'_3 \ldots > i'_n$, then $C'_1 > C'_2 > C'_3 \ldots > C'_n$.

For a practical visualization of the detail method the rainfall curve in Fig. 1 may be used with values of time and average intensities for Areas A_1, A_2, A_3, etc., as shown in Column (6) of Table 1. Assuming a constant value of r, say, 1.00 cu. ft. per sec. per acre and substituting in Equation (9), the values of intensities given in Table 1 (Column (6)): $C_1 = 0.80$; $C_2 = 0.71$; $C_3 = 0.65$; ... $C_n = 0.50$.

By a somewhat similar process of reasoning, it may be shown that when r varies directly as i a constant value of C results.

Referring again to the foregoing Conclusion (5), (by Mr. Kuichling), five assumptions may be made for illustrative purposes as follows:

(4) A given drainage area;
(5) A rain of considerable intensity, say 3 in. per hour;
(6) A rain of considerable intensity, say 6 in. per hour;
(7) Equal time periods; and,
(8) A constant value of C, say, 0.50.

Then, in Equation (9), $0.50 = 1 - \frac{r}{3.00}$, and $r = 1.50$ cu. ft. per sec. per acre. When $i = 6.00$ and $C = 0.50$, $r = 3.00$ cu. ft. per sec. per acre.

Stating the foregoing Conclusion (5) by Mr. Kuichling in words would be the equivalent of saying that for a given drainage area the capacity for retention, in cubic feet per second per acre, for a rain of 6 in. per hour is double that for a rain of 3 in. per hour; or, generally, that the capacity for retention of a given area varies directly as the intensity.

It is customary in the rational method (and properly so) to assume a certain existing wetness or degree of saturation, of a given area due to previous rains. This existing degree of saturation will always be one of the main determining factors in considering this rate of retention, and, consequently, the value of Factor C, including its variation with the time. Although the requirements of any particular problem must always tax the judgment of the individual engineer, it may be possible, in a future study of the run-off coefficient (through a more unified effort of the profession), to establish some kind of standard scale of previous degree of saturation to be used as a guide to this judgment.

Reverting to the consideration of Conclusions (11) and (12), the rate of retention (assuming a certain degree of previous wetness), may be subdivided into three main component parts, namely, evaporation, absorption, and storage.

There is no reason to assume any material difference in evaporation, in cubic feet per second per acre, from a given area due to two separate rains of considerable but different intensities. Likewise, there is no reason to assume a materially greater rate of absorption, expressed in cubic feet per second per acre, on a given area with a certain previous saturation from a rain of any considerable intensity than from one of less intensity severe enough to produce general run-off.

Considering storage, expressed in cubic feet per second per acre, a given area may be assumed to have a certain degree of previous saturation. For example, assume that on such an area a rain of considerable intensity, say, 3 in. per hour occurred. It is reasonable to suppose that, in addition to evaporation and absorption, a certain quantity of water is lost to run-off for the time of concentration by storage in irregularities of surface, vegetation (if any), etc. Before producing general run-off the water must overcome these factors. If, at another time, a rain of greater intensity, say, 6 in. per hour, should fall upon the same area with the same degree of previous wetness, it would have like storage irregularities, etc., to overcome before producing general run-off.

It is, therefore, not reasonable to assume that the storage capacity of a given area (in cubic feet per second per acre), which is in condition to shed its water, is twice as great for a rain of 6 in. per hour as that for one of 3 in. per hour; or, generally, that the capacity for storage of a given area varies directly as the intensity.

The foregoing analysis points to the correctness of Conclusions (11) and (12). Experimental proof showing the correctness of Conclusions (11) and (12) is not entirely lacking[8], although much work is to be done before comprehensive values of the run-off coefficient due to changing intensities, can be established for use in the rational method.

The range in intensities encountered in run-off studies is considerable, and the present tendency of many users of the detail rational method to increase Factor C as the time increases (as shown in current publications and textbooks), without also allowing for the fluctuation in C for changing intensities, seems entirely unjustified.

Conclusions.—Based on the foregoing analysis the writers make the following conclusions, which (it is hoped) may be of some use as guides to a proper selection of Factor C (the characteristics calculated to produce run-off and the previous degree of saturation are assumed to be constant for the individual areas forming the water-shed):

13.—For the type of storm with a uniform (or constant) intensity of rainfall over the entire area throughout the time of concentration of any water-shed, as A_n, with individual areas, $a_1 + a_2 + a_3$, etc. (see Table 1), Conclusion (10) as previously stated, is correct.

The increase of the run-off coefficient ($C_1 < C_2 < C_3$) depends on the previous degree of wetness, as well as the physical characteristics of the water-shed.

---

[8] Technical Reports, Miami Conservancy Dist., Pt. VIII, "Rainfall and Run-Off in the Miami Valley," by Ivan E. Houk, M. Am. Soc. C. E.

14.—When the expected storm for the time of concentration of any water-shed, as A_n, is of the type that decreases in intensity with the time, there is a tendency toward a balance in Factor C (see Conclusions (10), (11) and (12)). For average rates of retention, on the individual areas, a_1, a_2, a_3, ... a_n, or the areas, A_1, A_2, A_3, ... A_n, varying directly with the respective intensities, then $C'_1 = C'_2 = C'_3 \ldots = C'_n$, or $C_1 = C_2 = C_3 \ldots = C_n$.

Since it is manifestly the intention of the users of the detail process of the rational method to assume a storm of uniform intensity over the entire area throughout the time of concentration, the variable factor of safety (mentioned herein under the heading, "Use of Rainfall Curve"), may be considered as erring from the assumption due to the use of fictitious velocities. In this case Conclusion (13) applies in estimating the run-off from any water-shed, A_n.

However, while the run-off coefficients, C'_1, C'_2, C'_3, etc., correctly apply (under the assumption), to the areas, a_1, a_2, a_3, etc., in the process of estimating the "run-off collecting" at the outlet of the water-shed, A_n, they do not represent the proper values for use in the economical design of the drainage system. For design purposes Areas A_1, A_2, A_3, etc., must be considered as separate water-sheds. For instance, Area A_1, because of its shorter time of concentration, may be expected to receive a higher intensity than Area A_n, and, consequently, a higher run-off coefficient than the value used for it in estimating the run-off for the entire area.

Granting the correctness of Conclusions (10), (11), and (12), therefore, and permitting the use of velocities resulting from the detail method, the users of the customary tabling process, striving for economical design throughout the water-shed, should consider both the magnitude and duration of intensity on the contributing area.

Suggestion (*a*).—In regard to the application of intensities the rational method treats a given drainage area as a separate water-shed above each inlet point in succession on the main channel of flow, the smaller area receiving a higher uniform intensity throughout its time of concentration than the larger, of which it is a part. Those who use a constant run-off coefficient for a given type of territory (Assumption (2)), automatically assume, therefore, whether intentionally or otherwise, that, as progress is being made on a given rainfall curve, the average rate of retention on each successive water-shed varies directly as the intensity used; that is, that a balance is set up in the coefficient, an increase due to a greater average degree of saturation balancing the decrease due to a lower average intensity.

Stated in another way, the adoption of a constant coefficient (with respect to the time of concentration) for use with a certain rainfall curve, automatically assumes that degree of previous wetness of a given water-shed which will render a balance between the effects of increasing wetness and lowering intensity. Although the rate of retention may vary in different degrees for areas of dissimilar physical characteristics and shape, and the types of rainfall curves differ somewhat, in view of the extremely complicated nature of the problem and the necessary conflicts to be expected in experimental data, it may be the better part of wisdom at present to set up tentative tables on this basis to be used on the smaller water-sheds and the initial portions of the larger areas (say, the portion contributing during the first 60 to 120 min. of the time of concentration), on which it is desirable to assume an unsaturated surface condition at the outset of the maximum run-off producing intensity.

The making of such tables, among other considerations, would involve the selection of the best average shape; and would necessarily provide different sets of constants, as warranted by the change in average intensity due to frequency periods or location. The 60-min. ordinate could be made the criterion.

The use of such tables would entail the assignment by the designer of values of the coefficient to individual portions of the water-shed on the basis of physical characteristics, the column representing the frequency period of the curve in use having first been determined.

Suggestion (*b*).—For the smaller water-sheds and the portions of the larger areas (say, the portion contributing during the first 60 to 120 min. of the time of concentration), it may be feasible in the light of future experimentation to devise a set of curves (or tables) for elementary areas providing for both the effect of time and intensity on the various soils, degrees of perviousness, etc. It may be reasoned that the use of such curves (for instance, in the detail process) would require the estimation of an average value of the coefficient for the entire area above each inlet as new values of the intensity were selected from the rainfall curve.

Comment.—The uncorrected results of the tabling processes will, in any case, include the automatic error (or factor of safety above the assumption of a uniform intensity over the entire area throughout the time of concentration) noted under the heading, "Use of Rainfall Curve". Where provision is made for consideration of the effect of both time and intensity (as outlined under Suggestions (*a*) and (*b*), for water-sheds comparatively dry at the onset of the maximum run-off producing intensity), a similar error will be automatically included due to the use of an average value of the coefficient for the successive water-sheds above each inlet point, instead of the actual values for the individual areas. The magnitude of this latter error (for water-sheds of uniform characteristics throughout) will depend on the water-shed and the degree of previous wetness assumed, and will be smaller on the average, than that of the former. Both errors are on the side of safety, and, together (considering the approximate nature of the problem), are not of very serious consequence.

It should be evident that, for general use, either in the detail process, or in any method for estimating run-off, a table of values for the run-off coefficient should provide for changing intensities as well as for varying times.

PART II.—RATIONAL RUN-OFF FORMULAS

DERIVATION OF FORMULAS

In Equation (2) let $t = \frac{L}{v}$, then,

$$i = K \frac{v^e}{L^e} \quad \text{.........................} (10)$$

Substituting this value of i in Equation (1),

$$Q = C\,A\,K \frac{v^e}{L^e} \quad \text{........................} (11)$$

Let $R_H = \frac{X}{H}$, as, for example, $R_{0.5} = \frac{X}{0.5}$, etc. When $i = \frac{K}{t^e}$, $R_H = \frac{K}{(3\,600\,H)^e}$, the time being expressed in seconds; or,

$$K = R_H\,(3\,600\,H)^e \quad \text{......................} (12)$$

Velocity may be expressed by the Chezy formula,

$$v = c\,\sqrt{r\,s} \quad \text{............................} (13)$$

Substituting these values of K and v in Equation (11),

$$Q = (3\,600\,H)^e\,C\,A\,R_H\,\left(c\,\sqrt{r}\right)^e \frac{s^{\frac{e}{2}}}{L^e} \quad \text{...............} (14)$$

Comparisons.—It should be of interest here to digress temporarily, and convert Equation (14) into the form of the ordinary empirical formula.

If S = fall in feet per 1 000 ft. of channel, or $s = \frac{S}{1\,000}$; if the exponent, e, is given the value of 0.5; and if $R_H = R_1$ (the intensity in inches per hour for a period of 1 hour), then Equation (14) becomes,

$$Q = 10.67\,C\,A\,R_1\,\left(c\,\sqrt{r}\right)^{0.5} \frac{\sqrt[4]{S}}{\sqrt{L}} \quad \text{...............} (15)$$

The ordinary empirical formula takes no account of the shape of the drainage area; it is usually customary to assume (which later will be shown to be erroneous) that,

$$L = K'\,\sqrt{A} \quad \text{..........................} (16)$$

or some constant times $\sqrt{A}$. Assuming, for the purpose of illustration, that Equation (16) is correct, and substituting in Equation (15),

$$Q = 10.67\,K''\,\left(c\,\sqrt{r}\right)^{0.5}\,C\,R_1\,\sqrt[4]{S\,A^3} \quad \text{.............} (17)$$

It is interesting here to observe that Equation (17) results in the well-known Bürkli-Ziegler formula when the expression, $10.67\,K''\,\left(c\,\sqrt{r}\right)^{0.5}\,C$, is considered as a single run-off coefficient. The Hawksley formula may be reduced to similar terms for exponents of S and A, as shown[9] by the late Charles E. Gregory, M. Am. Soc. C. E. Since these and other empirical formulas neglect the shape of the drainage area, do not vary the fluctuating value of the average velocity, or its function $(c\sqrt{r})^e$, and make no allowance for a variation in the nature of the rainfall curve, results accurate enough for general use cannot be reasonably expected from their application.

---

[9] *Transactions*, Am. Soc. C. E., Vol. LVIII (1907), p. 461.

The value of L is independent of A, not only since the area may be any shape in so far as the exterior boundary is concerned, but also because the water may concentrate to the main channel in an infinite number of ways. To assume, then, that $L = K'\sqrt{A}$, not only presupposes a constant exterior shape of area, but also a constant law of concentration within the area, and is, of course, erroneous.

Introducing Factor F.—It follows, then, that in order to approach accuracy through the medium of a formula, the value of L should be retained, and the effect of velocity in the main channel of flow should be allowed to vary.

In Equation (14), the expression representing varying velocity, as far as shape and condition of the main channel of flow are concerned, is $(c\sqrt{r})^e$. At the present time, Kutter's formula for c in $c\sqrt{rs}$ is probably used more widely than any other; and, on account of its general adaptability to all shapes and conditions of channel, it affords a feasible basis for a variable velocity factor in run-off formulas. Since the velocity varies inversely as the time, the velocity factor, $c\sqrt{r}$, in a run-off formula, carries the exponent of the time, e. Due to the construction of rainfall curves this exponent varies in practice from about 0.4 to 0.6, the average probably being approximately 0.5.

In order to visualize more easily the effect of the fluctuating value of $c\sqrt{r}$ on run-off, the writers made many listings from "Hydraulic and Excavation Tables", published by the United States Reclamation Service. The process consisted of assuming first, a definite shape of channel, such as a circular pipe, or a closed rectangular box with a constant ratio of width to height. For a definite shape of channel on a given slope and Kutter's n, the hydraulic radius was allowed to vary, the corresponding velocity was selected from the hydraulic tables, and the values of Q, area, $c\sqrt{r}$, and $(c\sqrt{r})^{0.5}$, were calculated.

It was found that for any one definite shape of channel on a given slope and Kutter's n, $(c\sqrt{r})^{0.5}$, divided by $Q^{\frac{1}{8}}$, remained practically constant for all values of $c\sqrt{r}$ greater than 50 to 60, or,

$$(c\sqrt{r})^{0.5} \doteq N\,Q^{\frac{1}{8}} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (18)$$

in which, N represents a constant. More recent experimentation has shown that Kutter's formula is somewhat in error for very small sections. In selecting values of N (obtained by solving Equation (18)), choose from the Hydraulic Tables of the Reclamation Service, hydraulic radii rendering values of $c\sqrt{r}$ greater than 60; velocities may then be calculated, for the smaller sections, which are closer on the average to recent experimentation than those given by the use of Kutter's formula. In any case Equation (18) offers a reasonably accurate basis for obtaining a variable velocity factor, representing the shape and condition of the main channel of flow, for run-off formulas. The method of arriving at values of N and F is shown in more detail in the Appendix II.

As shown in Equation (14), $Q = (3\,600\ H)^e\ CAR_H\ \left(c\sqrt{r}\right)\ \dfrac{s^{\frac{e}{2}}}{L^e}$; but, hydraulically, $\left(c\sqrt{r}\right)^{0.5} = N\ Q^{\frac{1}{8}}$, or $c\sqrt{r} = N^2\,Q^{0.25}$. It must be remembered that the term, $c\sqrt{r}$, occurring in Equation (14), represents the average value of $c\sqrt{r}$ as determined by the average velocity of the water in running from the most remote part of the water-shed to its outlet. In this equation then, let $c\sqrt{r} = P\ N^2\ Q^{0.25}$, or,

$$\left(c\sqrt{r}\right)^e = P^e\ N^{2e}\,Q^{\frac{e}{4}} \quad\text{.....................}(19)$$

Methods of arriving at values of P are discussed subsequently in this paper.

Substituting $s = \dfrac{S}{1\ 000}$, and the value of $\left(c\sqrt{r}\right)^e$ shown in Equation (19), into Equation (14),

$$Q = \frac{(3\,600\ H)^e}{(1\,000)^{\frac{e}{2}}}\,CAR_H\ P^e\ N^{2e}\ Q^{\frac{e}{4}}\,\frac{S^{\frac{e}{2}}}{L^e} \quad\text{...............}(20)$$

From Equation (18), $N = \dfrac{\left(c\sqrt{r}\right)^{0.5}}{Q^{\frac{1}{8}}}$, that is, $N \propto \dfrac{1}{Q^{\frac{1}{8}}}$; but $Q =$ area $\times \left(c\sqrt{r\,s}\right)$. Therefore, Q, for a given channel, may be considered to vary directly as the square root of s, since the value of c varies only slightly with a change in slope. Then, it may be written that $Q \propto S^{\frac{1}{2}}$; and, since $N \propto \dfrac{1}{Q^{\frac{1}{8}}}$, $N \propto \dfrac{1}{S^{\frac{1}{16}}}$, or, $N = \dfrac{F}{S^{\frac{1}{16}}}$, in which, F represents a constant (see Appendix II).

Then,

$$N^{2e} = \frac{F^{2e}}{S^{\frac{e}{8}}} \quad\text{.........................}(21)$$

Substituting this value of N^{2e} in Equation (20),

$$Q = \frac{(3\,600\ H)^e}{(1\,000)^{\frac{e}{2}}}\,CAR_H\ P^e\ Q^{\frac{e}{4}}\,F^{2e}\ \frac{S^{\frac{3e}{8}}}{L^e} \quad\text{...............}(22)$$

$$Q^{1-\frac{e}{4}} = \frac{(3\,600\ H^e)}{(1\,000)^{0.5e}}\ CAR_H\ P^e\,F^{2e}\ \frac{S^{\frac{3e}{8}}}{L^e} \quad\text{.............}(23)$$

or, if the exponent, $\dfrac{1}{4-e} = g$:

$$Q = \frac{(3\,600\ H)^{4eg}}{(1\,000)^{2eg}}\left(\frac{P}{L}\right)^{4eg}(CAR_H)^{4g}\,F^{8eg}\,S^{1.5eg} \quad\text{............}(24)$$

Equation (24) is a general expression for the value of Q with seven main factors: C, A, R_H, S, P, F, and L. Factor C, of course, should be determined from experimental information, while A, S, and L must be derived from topographical maps or surveys.

Factor F varies with the shape and condition of the main channel of flow. Values for this factor may be selected from Table 11 in Appendix II. Factor P may be selected from Tables 3 and 4. The method used for the derivation of the values in these tables is discussed in another part of this paper.

Factor R_H is necessarily involved with H and e. The combination renders flexibility in the choice of the time period for observation of rainfall data, the type of rainfall curve, and storms of various expected frequency periods. Thus, for the smaller areas, it may be found advisable to choose 1 hour as the guiding period for rainfall observation, in which case, $H = 1$ hour, and R_H is represented by R_1. For the larger areas circumstances may make more feasible the adoption of longer time periods, as $H = 6, 12, \ldots 24$, with $R_H = R_6$, R_{12}, or R_{24}, as the case may be. Thus, when $R_H = \frac{X}{H}$, the expected rainfall may be $4\frac{1}{2}$ in. for a period of 6 hours. The average expected rainfall intensity expressed in inches per hour, for a 6-hour period, equals $R_H = \frac{X}{H} = \frac{4.5}{6.0} = 0.75$. The exponent, e, of the time in Equation (2) determines the type of rainfall curve.

INADEQUACY OF EMPIRICAL FORMULAS

At this point the reader may gain, by comparison, a more thorough comprehension of the inadequacy of the leading formulas of the empirical type, the construction of which offers opportunity for variation only in Factors C, A, R, and S. This comparison may be clarified by five statements as follows:

(*a*) Factor R_H of Equation (24) is represented in the empirical formula by R. The factor, R, in the empirical formula is usually assumed to represent the expected average rainfall intensity, in inches per hour, for a 1-hour period. This is, of course, a specialization of R_H.

(*b*) The exponent, e, of Equation (24) is necessarily given a constant value in any one empirical formula, thus rendering inflexibility in the choice of the type of the rainfall curve.

(*c*) Factor P of Equation (24), is, in any one empirical formula, given a constant value. The reader may gain some conception of the range of variation in this factor by a study of Tables 3 and 4.

(*d*) In the same manner, Factor F of Equation (24) is represented in any one empirical formula by some constant. Opportunity for measuring the effect on run-off, due to variation in shape and condition of the main channel of flow, is thereby rendered impossible. (See Table 11, Appendix II.)

(*e*) In the empirical formulas, in which the length of the main channel of flow, L, does not appear, the effect on run-off due to the shape of the area cannot be measured. The absence of L entails the assumption that it equals some constant times A to an exponent, as $L = K' \sqrt{A}$, thereby precluding the possibility of weighing the effect on run-off caused by varying the shape of the water-shed either in external boundary or manner of internal concentration.

Reduction of Equation (24)

This equation reduces to simpler terms, once the required data on rainfall are known. For example, should the rainfall data for a given locality point to the use of a curve following the equation, $i = \frac{K}{t^{0.6}}$, and should it be found advisable to use a 12-hour time period, then $H = 12$ and $e = 0.6$.

Substituting these values, Equation (24) reduces to:

$$Q = 163.5 \left(\frac{P}{L}\right)^{0.706} (C A R_{12})^{1.176} F^{1.412} S^{0.265} \ldots\ldots\ldots\ldots (25)$$

Thus, when H and e are once adopted, Equation (24) reduces to the seven main factors with definite exponents, prefixed with a constant. Where a formula of the type of Equation (25) is constantly in use, it probably would be found advisable to reduce it to four variables and solve by nomograph in two parts, such that $\left(\frac{P}{L}\right)^{0.706} \times (C A R_H)^{1.176}$ forms one nomograph, and $F^{1.412} S^{0.265}$, another. The formula also lends itself to quick solution by log-log slide-rule.

To find the time of concentration compute the value of i from Equation (1). For this purpose, Q is determined from Equation (24) reduced. The time, t, may then be read from a curve of Equation (2). If there is no diagram, t, in minutes, may be computed from Equation (2) by substituting for K its value in Equation (12) and dividing the result by 60; thus,

$$t = \frac{60\, H\, R_H^{\frac{1}{e}}}{i^{\frac{1}{e}}} \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (26)$$

Special Reduction of Equation (24).—It is realized that occasions may arise necessitating the estimation of run-off in territories where adequate rainfall records are not available. Even in localities where available records vary somewhat from average conditions, it may be found unnecessary, or economically inadvisable, to go into great refinement in the making of rainfall curves.

Mr. Grunsky[10] and others advocate the use of a rainfall curve of the form of Equation (3). Moreover, the writers have found that it applies very well to conditions in Southern California, as, for example, it conforms very closely to the curves now used by the City of Los Angeles, the Los Angeles County Flood Control Department, and the Los Angeles County Storm Drain Division. The writers, therefore, have developed the following special reduction with a twofold purpose in mind, namely, (*a*), to furnish a formula which will be approximately applicable for general use; and (*b*), one which may very readily be used for making quick transitions to other types of curves as subsequently recommended.

In Equation (24) if $e = 0.5$, $g = 0.2857$, and,

$$Q = 15\, H^{0.5714} \left(\frac{P}{L}\right)^{0.5714} (C A R_H\, F)^{1.1429} S^{0.2143} \ldots\ldots\ldots\ldots (27)$$

---

[10] *Transactions*, Am. Soc. C. E., Vol. LXXXV (1922), p. 67.

and since the expression, $\left(\frac{P}{L}\right)^{0.5714} = \left(\sqrt{\frac{P}{L}}\right)^{1.1429}$, Equation (27) may be written:

$$Q = 15\ H^{0.5714}\ (CAR_H\ F\ B)^{1.1429}\ S^{0.2143} \ldots\ldots\ldots\ldots\ldots (28)$$

in which, $\sqrt{\frac{P}{L}} = B$, which may readily be obtained by slide-rule.

Equation (28) reduces to two variables if the time period, H, is adopted, and the R_H value is determined from the relation, $R_H = \frac{X}{H}$. Hence, when $H = 1$ hour, Equation (28) reduces to:

$$Q = 15\ (CAR_1\ F\ B)^{1.1429}\ S^{0.2143} \ldots\ldots\ldots\ldots\ldots (29)$$

Whenever the adopted rainfall curve varies materially from Equation (3), use may be made of Equation (28) to give an approximate value of Q to be corrected as follows:

Substitute the values of Q, C, and A, of Equation (28) in Equation (1) and solve for i. Then obtain the time, t, in minutes, from a diagram of Equation (3), or by solving Equation (26). Using this value of t, obtain a corresponding value of i from the curve in use. With this value of i solve Equation (1) for a corrected Q, which will be a close approximation to the quantity of run-off to be expected from the use of the adopted rainfall curve.

METHOD OF ARRIVING AT VALUES OF FACTOR P

Factor P has been defined as the ratio of the average velocity of flow to velocity at the outlet of the water-shed, based on average values of S and F or $P = \frac{v}{V}$. Upon inspection of Equation (24), reduced to its seven main factors—C, A, R_H, S, P, F, and L—it may be readily seen that when average values for a given water-shed are assigned to Factors S, F, C, and R_H (these factors then assume the rôle of constants in the formula), the variation in Factor P is determined by the remaining two factors, A and L. The fluctuation in Factor P, therefore, depends on the shape of the drainage area, both as to external boundary and internal concentration.

It is evident, of course, that P may have an infinite number of values. Since, in any rational method of estimating run-off, inlet time must be considered, the value of P is further complicated. Factor $P = \frac{v}{V}$; but $v = \frac{L}{t}$, in which, t = time of concentration of the water-shed, including the initial, or inlet, time of the first small area, or nucleus.

Before attempting to devise a table of values for Factor P it was necessary to investigate both the use of the rainfall curve and the run-off coefficient (particularly as regards its variation with the time). The reader at this point is assumed to be familiar with the conclusions under headings, "Use of Rainfall Curve," and "Factor C, The Run-Off Coefficient." For a given area it may be reasoned that:

(*a*) The use of a factor, C, increasing with the time would give a value of P somewhat lower than a constant C.

(*b*) The use of a factor, C, decreasing with the time would give a value of P somewhat higher than a constant C.

(*c*) The type of storm assumed for a given water-shed has a certain effect on the expected run-off. This effect influences not only the run-off coefficient, but also Factor P. If, for a given area, it is assumed that the storm for the time of concentration decreases in intensity with the time, a somewhat higher value of P results than that for the assumption that the storm is one of uniform intensity throughout.

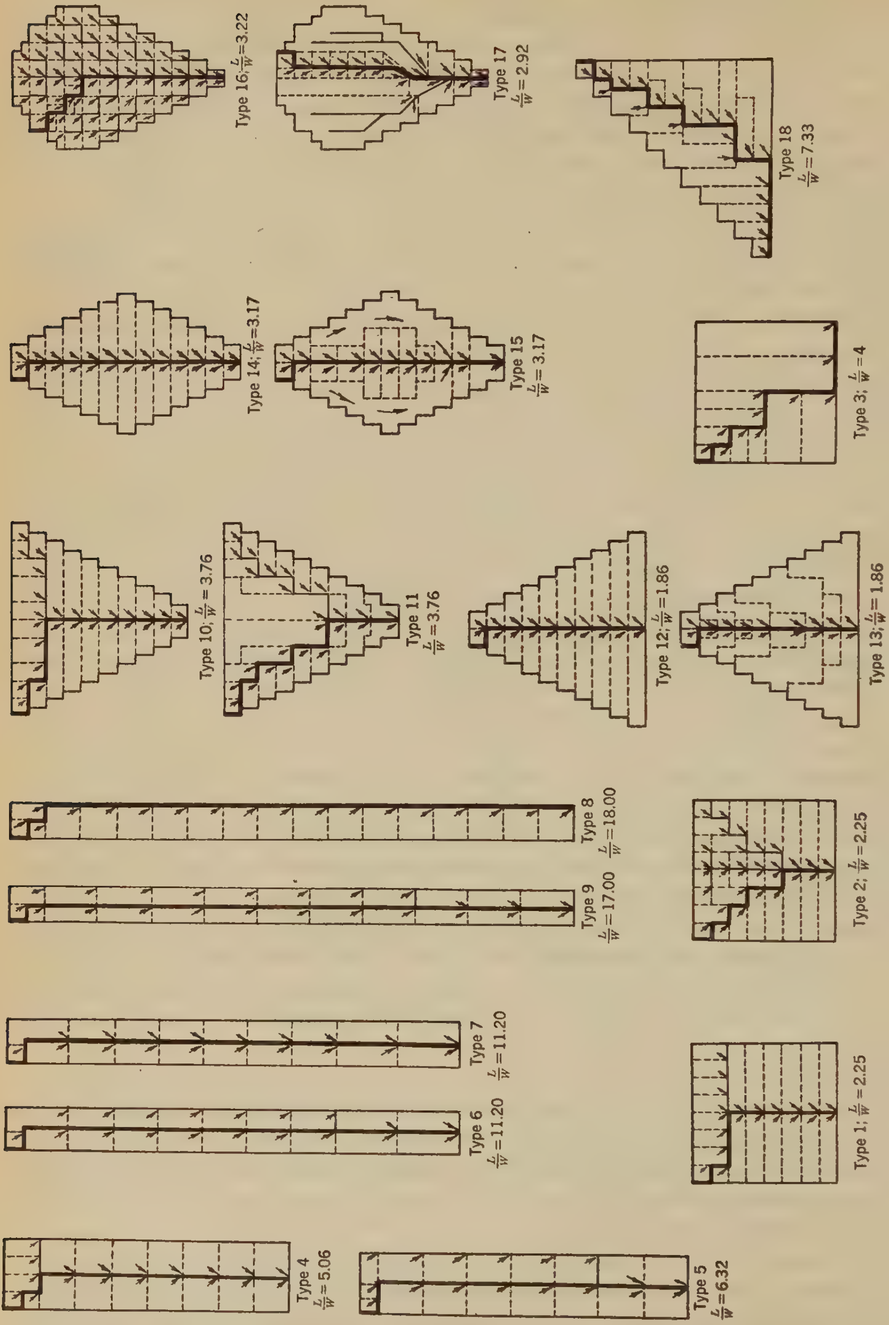
The effects on Factor P of the foregoing considerations under Paragraphs (*a*), (*b*), and (*c*), are, however, not of major importance, since (except for extreme conditions) the final run-off is varied only a few per cent. one way or the other. The latitude for variation in the run-off result, due to errors in judgment in choosing values for Factor C, R_H, and F, is large in comparison; but, on account of the many varying conditions entering into the estimation of run-off by any method, the engineer, as far as practicable, should be able to visualize all limitations or advantages of any particular formula or system.

Estimation of run-off inevitably depends to a great extent on individual judgment. The writers, in evolving formulas, are merely attempting to aid this judgment in a quick solution. In the face of so many variations it would be highly impracticable to attempt a mathematical solution of P for the purpose of making the tables of values for use in the formulas. It is possible, however, to establish workable tables by trial method, that should be far superior at least to the use of a constant (single) value of this factor, as is automatically done when an empirical formula is used. An average, or constant, value of C was used in preparing Tables 3 and 4. The values in Table 3 are based on the assumption of a storm of uniform (or constant) intensity for the time of concentration. Hence, a constant intensity throughout was used on any one area type shown in Fig. 2. Table 3, therefore, should be used when the assumption is that the expected storm is one of uniform intensity for the time of concentration. Referring to Conclusion (13) under "Factor C, The Run-Off Coefficient" (Part I), it may be seen that the use of this table carries with it a small factor of safety, which is comparable with, but smaller than, that automatically assumed in the usual detail process of the rational method (see "Statement" following Conclusion (4)); and its use, rather than being objectionable, is to be commended, especially when the possible variation in types of storms is taken into consideration.

The values in Table 4 were evolved through the use of a rainfall curve of the type of Equation (3), in the manner ordinarily used in the detail process of the rational method. This table, therefore, involves the small factor of safety resulting from the use of Equation (3) as ordinarily practiced in the detail rational method.

Values of P in Tables 3 and 4 may be used in any formula reduced from Equation (24). In preparing Tables 3 and 4, the procedure was as follows:

1.—Areas, shown on Fig. 2, were chosen for the purpose of establishing practical limits of shape, so that interpolations could be made for values of P.



Type 4 $\frac{L}{W}=5.06$
Type 5 $\frac{L}{W}=6.32$
Type 6 $\frac{L}{W}=11.20$
Type 7 $\frac{L}{W}=11.20$
Type 1; $\frac{L}{W}=2.25$
Type 9 $\frac{L}{W}=17.00$
Type 8 $\frac{L}{W}=18.00$
Type 2; $\frac{L}{W}=2.25$
Type 10; $\frac{L}{W}=3.76$
Type 11 $\frac{L}{W}=3.76$
Type 12; $\frac{L}{W}=1.86$
Type 13; $\frac{L}{W}=1.86$
Type 14; $\frac{L}{W}=3.17$
Type 15 $\frac{L}{W}=3.17$
Type 3; $\frac{L}{W}=4$
Type 16; $\frac{L}{W}=3.22$
Type 17 $\frac{L}{W}=2.92$
Type 18 $\frac{L}{W}=7.33$

FIG. 2.—TYPICAL AREAS AND THEIR MANNER OF CONCENTRATION

2.—In making Table 3, a constant intensity and an average value for each of the factors, S, C, and F, were used on any one area type.

3.—In the case of Table 4, a value (any practical value) for each of the factors, S, C, R_H, and F, was chosen, the same values being used on all areas.

4.—The areas were subdivided for concentrating the water to the main channel of flow (shown on Fig. 2) anticipating, as far as practicable, actualities to be met in drainage practice. For purposes of interpolation the manner of concentration along the main channel of flow was designated advanced, medium, or delayed, concentration. What constitutes the three types of concentration may best be ascertained by studying Tables 3 and 4, and Figs. 2 and 4. Extreme delay or advancement was avoided.

5.—It was necessary to assume a beginning nucleus, or initial area. For the purpose of striking the best average a square nucleus, with the value of $\frac{L'}{W'} = \frac{L'}{\frac{43\,560\,A'}{L'}} = \frac{(L')^2}{43\,560\,A'} = 4$. For the purpose of providing a sufficient range of interpolation for values of P to meet the expected need, varying values of P', ranging from 0.1 to 2.0, were used on the various area types. The value of $P_1 = \frac{v'}{V'}$, is to be corrected for use in Tables 3 and 4 through reference to Fig. 3, giving P'. Thus, in Tables 3 and 4,

$$P' = f\,P_1 = f\,\frac{v'}{V'} \quad\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots(30)$$

in which, f is a correction factor read from Fig. 3.

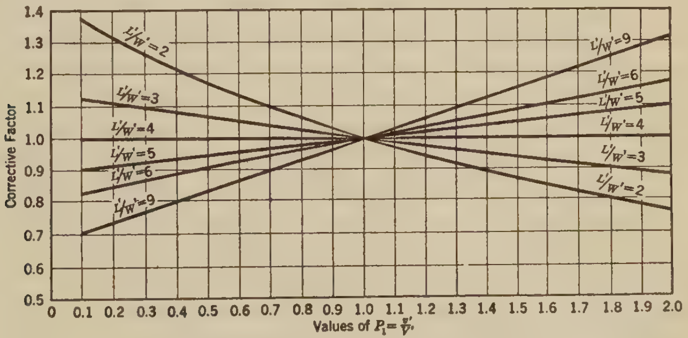


FIG. 3.—DIAGRAM TO DETERMINE CORRECTION FACTOR IN EQUATION (30).

For areas of the same shape and manner of concentration the value of P is the same (irrespective of the size of the area) for a given assumption of P' on the nucleus. However, in order to have the same manner of concentration, the nucleus of each area must be of the same shape and must vary in size with the area of the water-shed. It follows, then, that when the size and shape of the nucleus remain the same in all areas of similar shape and manner of concentration, the value of P changes somewhat with the area.

In Tables 3 and 4 a constant nucleus was used; hence, the variation in P with the area divided by area of nucleus as shown.

The ratio, $\frac{L}{W}$, in these tables was adopted as a practical means of helping to define the change in area shape when used in conjunction with the typical areas shown in Fig. 2, which are also intended for guides as to the manner of internal concentration. The ratio, W, equals area of water-shed, in square feet, divided by L. Hence,

$$\frac{L}{W} = \frac{L^2}{43\,560\,A} \quad \text{(31)}$$

Fig. 4 will be found useful in the determination of delayed, medium, or advanced concentration. This diagram is intended to be used as an aid in determining the manner of concentration. The numbered points refer to the area types shown on Fig. 2. The relative positions of the various points for a given value of P' were determined by using values of P for abscissas (not shown on the diagram to attain compactness), and $\frac{L}{W}$ for ordinates.

P' having been determined, and the area type on Fig. 2 (most nearly representing the area being studied) selected, enter Fig. 4 under the value of P' and note the position of the area type with respect to the concentration lines marked "Delayed", "Medium", and "Advanced"; then enter Table 3 or Table 4 under the heading of the concentration chosen on Fig. 4.

The manner of concentration of a given water-shed, designated in this work, delayed, medium, or advanced, is, of course, determined by the relative quantities of water gathering to the main channel of flow. In small areas these relative quantities may be contributed by individual subdivisions without well-defined channels of flow (such as a city block); in larger water-sheds these contributions may be represented by laterals; and in still larger ones by creeks, or rivers, as may be visualized by a glance at a topographical map of a large mountainous area. Hence, the area types on Fig. 2 may be used for an area of any size, the sketches being intended only to aid the judgment. It is realized, of course, that the method is not perfect, and that it is capable of expansion or improvement, since there is no limit to the number of area shapes; yet the writers hope that it may at least be helpful.

Although it would be impractical to solve mathematically for all values of P, the following two analytical solutions may serve to help the reader in forming a conception of the factor's usefulness.

Let Fig. 5(a) and Fig. 5(b) represent water-sheds of triangular and rectangular shapes, as shown, each subjected to uniform intensities, the water being assumed to concentrate uniformly to the main channels of flow, designated by the heavy lines. The run-off coefficient is assumed to be constant, and the velocities (combining Equations (13) and (18)) in the main channels of flow are determined by,

$$v = N^2\, Q^{\frac{1}{4}}\, s^{\frac{1}{2}} \quad \text{(32)}$$

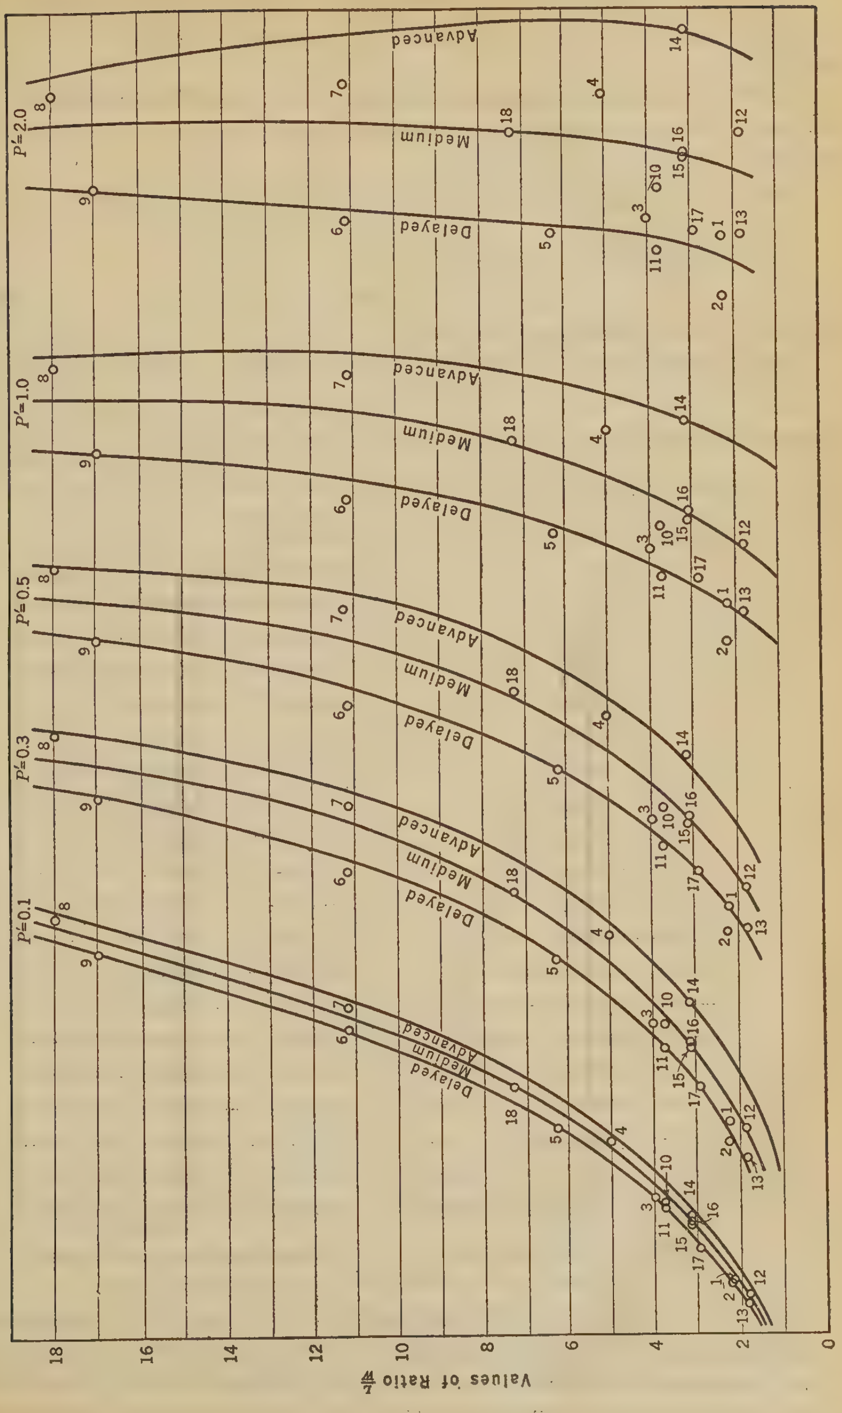

FIG. 4.—GUIDE LINES TO AID IN DETERMINATION OF THE MANNER OF CONCENTRATION

Example 1.—The Triangular Water-Shed.—In Fig. 5(*a*) the shape of the water-shed above any point on the main line is the same; that is, $L \propto \sqrt{A}$, or $A \propto L^2$.

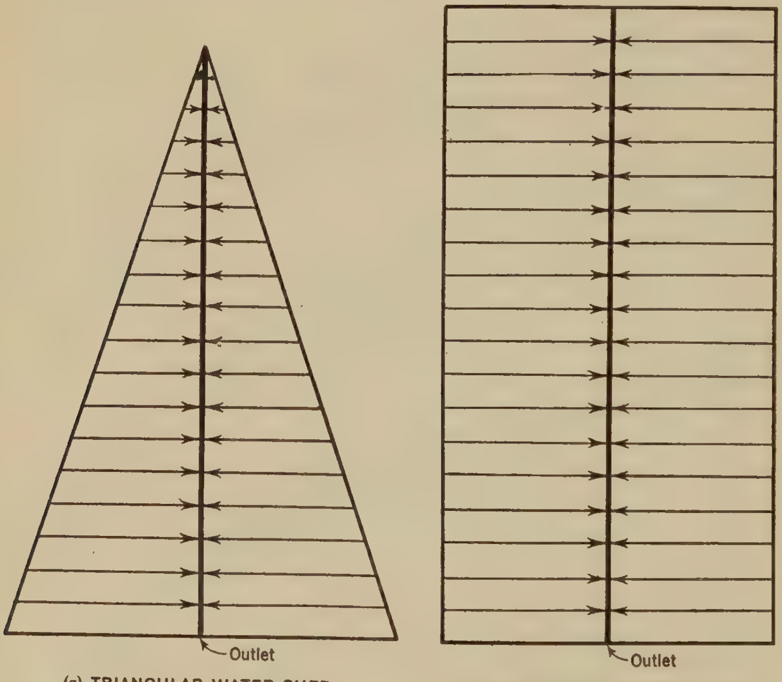
Under the foregoing assumptions the run-off, Q, concentrating to points on the main line, varies directly as the contributing area, or, $Q \propto A$; and, hence, $Q \propto L^2$.

Since $v \propto Q^{\frac{1}{4}}$ (see Equation (32)), $v \propto (L^2)^{\frac{1}{4}} \propto L^{\frac{1}{2}}$; but since $t = \frac{L}{v}$, $t \propto \frac{L}{L^{\frac{1}{2}}} \propto L^{\frac{1}{2}}$, therefore, $v \propto t$, or,

$$v = M\,t \qquad \text{(33)}$$

in which, M represents some constant.

The average value of v may be found as follows: When $v = M\,t$, the expression for the area, $v\,t$ $(= L)$, is $\int M\,t\,dt$, or $\frac{1}{2}\,M\,t^2$; and $\dfrac{\frac{1}{2}\,M\,t^2}{t} = \frac{1}{2}\,M\,t$, or the average velocity, is one-half the maximum velocity. Thus, the value of $P = \frac{v}{V}$, under the foregoing assumptions, is one-half.



(*a*) TRIANGULAR WATER SHED

(*b*) RECTANGULAR WATER SHED

FIG. 5.—DIAGRAMS TO INDICATE THE USEFULNESS OF THE FACTOR *P*

Example 2.—The Rectangular Water-Shed.—The value of P for this shape is an impractical one, because the time of concentration of the water to the main line can not be taken into account; but its determination is of value for purposes of illustration and comparison. In Fig. 5(*b*) it may be seen by inspection that the length, L (measured from the top of the water-shed to any point on the main line), varies directly as the contributing area to that point, or $L \propto A$; and since (as before), $Q \propto A$, then $Q \propto L$. Since $v \propto Q^{\frac{1}{4}}$, $v \propto L^{\frac{1}{4}}$ Furthermore,

$$t = \frac{L}{v} \dots\dots\dots\dots\dots\dots\dots\dots\dots (34)$$

and, hence, $t \propto \dfrac{L}{L^{\frac{1}{4}}} \propto L^{\frac{3}{4}}$, or, $L \propto t^{\frac{4}{3}}$; therefore, since $v \propto L^{\frac{1}{4}}$, $v \propto \left(t^{\frac{4}{3}}\right)^{\frac{1}{4}} \propto t^{\frac{1}{3}}$, or,

$$v = M'\, t^{\frac{1}{3}} \dots\dots\dots\dots\dots\dots\dots\dots\dots (35)$$

Therefore, $\int M'\, t^{\frac{1}{3}}\, dt = \dfrac{3}{4} M'\, t^{\frac{4}{3}} =$ area, $v\, t\ (= L)$, and $\dfrac{\frac{3}{4} M'\, t^{\frac{4}{3}}}{t} = \dfrac{3}{4} M'\, t^{\frac{1}{3}} =$ the average velocity. Thus, the average velocity is three-fourths the maximum velocity, or $P = \dfrac{v}{V} = \dfrac{3}{4}$.

Remarks and Deductions.—Fig. 5(a) represents a closed water-shed, the water concentrating uniformly to the main channel of flow, and, since the shape of the water-shed is the same above points along the main line, the value of P is constant, as deduced in Example 1.

Fig. 5(b) represents a water-shed which is not closed, since no time has been allowed for the water to concentrate to the main channel, designated by the heavy line. The value of $P = \dfrac{3}{4}$, as deduced in Example 2, is, therefore, of significance only in illustrating the values in Table 3, evolved from the practical limiting shapes, shown in Fig. 2.

Referring to Types 1 to 9, inclusive, of Fig. 2 and to Fig. 4 and Table 3, it may be noted that, for a given value of P', the value of P becomes higher as $\dfrac{L}{W}$ increases. The value of $P = \dfrac{3}{4}$ (for Fig. 5(b)) is approached as $\dfrac{L}{W}$ increases, the initial delay being caused by the natural division of the water in concentrating; hence, the choice of $\dfrac{L}{W}$ as a guiding influence in the determination of Factor P for the limiting shapes of Fig. 2.

Referring to Table 3, it is apparent that the column headed by $\dfrac{A}{A'}$ is necessitated by the inclusion of varying values for P', or the provision for assignment of an initial time for the inlet area. This provision was made in order to create possibilities for the broadest use of the formulas. It is evident, however, that for many water-sheds, especially the larger ones, the consideration of the inlet area as a separate entity, may be unnecessary. In this case, the water-shed is neither delayed, nor advanced by the inlet areas, and its condition at the outset of the maximum run-off producing intensity is ready for the falling water to begin concentrating immediately.

When the inlet area is not considered separately, the slope, S, of the water-shed must be based on the total slope from the most remote area (including the nucleus) to the outlet, and the value of $\frac{A}{A'}$ in Table 3 must be considered as infinite.

As $\frac{A}{A'}$ increases (see Table 3), the values of P decrease under the columns headed by the higher values of P' and increase for the lower values of P'. The natural convergence of these values as $\frac{A}{A'}$ approaches infinity is approximately to the column headed by $P' = 0.5$.

For all practical purposes, therefore, the values of P (in Tables 3 and 4) shown opposite $\frac{A}{A'} = 262\ 144$, and in the column headed by $P' = 0.5$, may be used when the formulas are applied without separate consideration of the inlet area, or nucleus.

The Inlet Area, or Nucleus

In any rational method of estimating run-off special consideration in many cases should be given to the choice of the beginning area of the water-shed. The time of concentration for the water-shed includes the time required for the water to gather in the first small area, or nucleus, and travel to a defined channel of flow. This beginning area is a small water-shed and its time of concentration is the time required for the water to travel from the most remote portion to its outlet. The average velocity of the nucleus may be defined as the distance which the water must travel from the most remote portion to the outlet, divided by its time of concentration. This average velocity, in the same small nucleus (such as a city block), may consist of flow over grass plots, driveways, and gutters; in rural areas, it will be retarded by vegetation, or increased by barrenness.

It is customary for those who use the detail process to assume an inlet time, which is based on field observations. Reliable data on inlet time are scarce, and more experimentation is needed.

For some water-sheds the run-off formulas herein may be applied without separate consideration of the nucleus. For all water-sheds the formulas may be used to approximate the expected value of Q and to estimate times of concentration without separate consideration of the nucleus.

When the surface of the water-shed is in a saturated condition at the onset of the maximum run-off producing intensity, the inlet time of concentration for a high intensity will be shorter than that for lesser ones, due only to the greater quantity of water flowing. If the surface is not saturated the time of concentration for the greater intensities will be shorter than for lesser ones, due both to the greater quantity of water flowing and to a shorter period required for saturating the surface sufficiently for run-off to occur.

In any method of computing run-off great care should be used in choosing the main channel of flow on which the time of concentration for the water-shed so largely depends. The run-off, Q, sought for a given water-shed is the maximum that may be had for definite assumptions on rainfall. For some areas, with extreme contrasts in values of characteristics governing the run-off coefficient, and slope, shape, and condition of the main channel of flow, a part of a given water-shed may be found to give a greater run-off than the whole.

Experience is of value in the choice of the main channel of flow; but, even so, it may sometimes be found necessary to determine it by trial.

The initial area, or nucleus, is a part of the water-shed (and the length, L, of the water-shed includes L' of the nucleus). Consequently, the choice of the nucleus plays no small part in the determination of the maximum run-off. A good conception of the influence of the nucleus may be had from a study of Tables 3 and 4.

AVERAGE SLOPE

Heretofore, in using formulas for the estimation of run-off, the writers have been unable to determine a practical method for calculating the average slope. Of course, the slope should be that of the main channel of flow, that is, the channel which determines the time of concentration of the water-shed.

The average hydraulic slope is not the average of the various slopes weighted by the individual lengths, the sum being divided by the total length as, $S = \frac{1}{l}(L_1 S_1 + L_2 S_2 + L_3 S_3 \text{ etc.})$, in which, l equals the sum, $L_1 + L_2 + L_3$, etc. By inspection it may be seen that this average slope is identical with $S = \frac{\text{total fall}}{\text{total length}}$, which would be easily obtained.

Average hydraulic slope depends on the velocities induced by the individual slopes. The average velocity, therefore, will be induced by the true average hydraulic slope. Since the average velocity equals the total length divided by the time, or $v = \frac{l}{t}$, it may be seen that the true average hydraulic slope is that which, with a given quantity of water flowing through length, l, will cause the same total length of time to elapse as that consumed in traveling the slopes, S_1, S_2, S_3, etc.

In Equation (32), $v = N^2 Q^{\frac{1}{4}} \sqrt{s}$, or $v \propto N^2 \sqrt{S}\, Q^{\frac{1}{4}}$. Since $N = \frac{F}{S^{\frac{1}{16}}}$ (according to Equation (21)), $v \propto F^2 S^{\frac{3}{8}} Q^{\frac{1}{4}}$; but the time, t, varies as length divided by velocity, or $t \propto \frac{l}{v} \propto \frac{l}{F^2 S^{\frac{3}{8}} Q^{\frac{1}{4}}}$. It follows, therefore, that if the average hydraulic slope is to cause the same lapse of time as that consumed by the water in traversing the individual slopes, S_1, S_2, S_3, etc.,

$\frac{1}{S_1^{\frac{3}{8}}}, \frac{1}{S_2^{\frac{3}{8}}}, \frac{1}{S_3^{\frac{3}{8}}}$, etc., should be weighted by $\frac{L_1}{F_1^2\ Q_1^{\frac{1}{4}}}, \frac{L_2}{F_2^2\ Q_2^{\frac{1}{4}}}, \frac{L_3}{F_3^2\ Q_3^{\frac{1}{4}}}$, respectively. For example,

$$\frac{1}{S^{\frac{3}{8}}} = \frac{\dfrac{L_1}{F_1^2\ Q_1^{\frac{1}{4}} S_1^{\frac{3}{8}}} + \dfrac{L_2}{F_2^2\ Q_2^{\frac{1}{4}}\ S_2^{\frac{3}{8}}} + \text{, etc.}}{\dfrac{L_1}{F_1^2\ Q_1^{\frac{1}{4}}} + \dfrac{L_2}{F_2^2\ Q_2^{\frac{1}{4}}} + \text{, etc.}}$$

or, inverting,

$$S^{\frac{3}{8}} = \frac{\dfrac{L_1}{F_1^2\ Q_1^{\frac{1}{4}}} + \dfrac{L_2}{F_2^2\ Q_2^{\frac{1}{4}}} + \text{, etc.}}{\dfrac{L_1}{F_1^2\ Q_1^{\frac{1}{4}}\ S_1^{\frac{3}{8}}} + \dfrac{L_2}{F_2^2\ Q_2^{\frac{1}{4}}\ S_2^{\frac{3}{8}}} + \text{, etc.}} \qquad \ldots\ldots\ldots\ldots(36)$$

Thus, $S^{\frac{3}{8}}$, and then S, the average slope, may be solved.

Example 3.—F and Q Constant.—Either s or S may be used throughout; F and Q, being constant, drop them from Equation (36) and assume $L_1 = 1\ 848$ ft., with $S_1 = 90$, and $L_2 = 8\ 316$ ft., with $S_2 = 0.9$ then (computations by slide-rule) substituting these values in Equation (36), $S^{\frac{3}{8}} = 1.131$; and $S = 1.39$ ft. per 1 000 ft.

A check on this answer is as follows: Assume that $Q = 200$ cu. ft. per sec., and that $F = 6.63$, then by Equations (21) and (32),

$$v = N^2 \sqrt{s}\ Q^{\frac{1}{4}} = \frac{F^2}{S^{\frac{1}{8}}} \sqrt{s}\ Q^{\frac{1}{4}} \qquad \ldots\ldots\ldots\ldots\ldots\ldots(37)$$

Substituting the assumed values in Equation (37), $v_1 = 28.3$ ft. per sec.; and $t_1 = \frac{L_1}{v_1} = \frac{1848.0}{28.3} = 65$ sec.

Similarly (see Equation (37)), $v_2 = \frac{44.0}{0.988} \times 0.03 \times 3.76 = 5.0$ ft. per sec.; $t_2 = \frac{8\ 316}{5.0} = 1\ 655$ sec.; and $t = t_1 + t_2 = 65 + 1\ 655 = 1\ 720$ sec. (actual time).

Using the average slope, $S = 1.39$, in Equation (37), $v = 5.91$ ft. per sec.; and $t = \frac{l}{v} = \frac{10\ 164}{5.91} = 1\ 720$ sec., which checks the time on individual slopes.

Example 4.—F Constant and Q Varying.—In this case, only F drops from Equation (36). Assume that $L_1 = 1\ 848$ ft., with $S_1 = 90$ and $Q_1 = 10$ cu. ft. per sec., and $L_2 = 8\ 316$ ft., with $S_2 = 0.9$ and $Q_2 = 656$ cu. ft. per sec. Then, substituting in Equation (36) as before, $S^{\frac{3}{8}} = 1.41$, and $S = 2.50$ ft. per 1 000 ft.

As a check, assume that $F = 6.63$, then, by Equation (37): $v_1 = \frac{44.0}{1.755} \times 0.3 \times 1.776 = 13.36$ ft. per sec., and $t_1 = \frac{1\ 848}{13.36} = 138$ sec. Similarly, (see Equation (37)), $v_2 = 6.76$ ft. per sec., and $t_2 = 1\,230$ sec. As in Example 3, $t = t_1 + t_2 = 138 + 1\,230 = 1\,368$ sec. (actual time).

Using the average slope, $S = 2.50$ in Equation (37), $v_1 = 3.49$ ft. per sec., and $t_1 = \frac{1\,848}{3.49} = 530$ sec. Likewise, $v_2 = 9.94$ ft. per sec., and $t_2 = \frac{8\,316}{9.94} = 837$ sec. As before, $t = t_1 + t_2 = 530 + 837 = 1\,367$ sec., which checks the total time on the individual slopes.

Example 5.—F and Q Varying.—In this case, Equation (36) is used directly. For instance, assume that $L_1 = 9\,240$ ft., with $S_1 = 90$, $F_1 = 5.0$, and $Q_1 = 200$ cu. ft. per sec., and $L_2 = 7\,392$ ft., with $S_2 = 0.9$, $F_2 = 7.0$, and $Q_2 = 800$ cu. ft. per sec.

Substituting the proper values in Equation (36), $S^{\frac{3}{8}} = 2.65$ and $S = 13.52$ ft. per 1 000 ft. A check on this average value of S may be made as in Examples 3 and 4.

Practical Use of Method.—The foregoing method of estimating the true average hydraulic slope will be found useful, no doubt, in general hydraulic work. It will be found especially useful in run-off formulas when the slope of the main line of flow of the water-shed changes materially.

In the run-off formulas the exponent of the slope is, of course, determined by the type of rainfall curve. For instance, when the curve is of the type of Equation (2), and e has the value 0.4, 0.5, or 0.6, there results approximately $S^{0.167}$, $S^{0.214}$, $S^{0.265}$, respectively, for use in the run-off formulas. On account of the smallness of these exponents in the average formula, extreme refinement in estimating the average slope is unnecessary. However, the extreme differences in slopes of sections of the main channel, encountered in many water-sheds, require a rational approach to the true average slope. The refinement resorted to should depend both on these differences and on the requirements of the particular problem at hand. The water-shed may be divided into two, or more, parts, according to the judgment of the engineer.

When the expected storm is assumed to have a uniform (or constant) intensity for the time of concentration, Q varies directly as the product, CA. It may be seen, therefore, that, for this assumption, the product, CA, may be substituted for Q in Equation (36).

Products $C_1\,A_1$, $C_2\,A_2$, $C_3\,A_3$, etc., represent the average relative Q_1, Q_2, Q_3, etc., contributing to individual slopes, S_1, S_2, S_3, etc., respectively. Since the relative Q, in the foregoing method for estimating the average slope (see Equation (36)), carries the exponent of $\frac{1}{4}$, its value (or product, $C\,A$) may be roughly approximated without affecting the final run-off result materially.

Substitution of $S^{\frac{1}{2}}$ for $S^{\frac{3}{8}}$ in Equation (36) renders a fairly close approximation for the average slope. The resulting slope is a little smaller than that obtained by using $S^{\frac{3}{8}}$.

AVERAGE VALUE OF F

Having observed the foregoing method for estimating the average slope, it should be evident that the following equation may be used in arriving at the average value of F, for use with the average slope (substituting $C\,A$ for the relative Q):

$$F^2 = \frac{\dfrac{L_1}{(C_1\,A_1)^{\frac{1}{4}}} + \dfrac{L_2}{(C_2\,A_2)^{\frac{1}{4}}} + \text{etc.}}{\dfrac{L_1}{(C_1\,A_1)^{\frac{1}{4}}\,F_1^2} + \dfrac{L_2}{(C_2\,A_2)^{\frac{1}{4}}\,F_2^2} + \text{etc.}} \qquad (38)$$

AVERAGE VALUE OF C

The proper assignment of values to the run-off coefficient requires an intimate knowledge of all the various factors affecting run-off as well as a fund of experimental information from which to draw. The refinement to which the engineer should resort in establishing its value depends both on the particular problem confronting him and the reliability of available information.

Values for Factor C can be secured only through experimentation by obtaining field measurements for A, i, and Q; and solving by Equation (1). Some of the information presented in current textbooks and past and present publications has been procured on this basis; various tables of values for C (especially for use in storm drain work) are listed. However, much of the available information is of a conflicting nature, due in some cases, no doubt, to unreasonable conceptions, and in others to conclusions drawn from insufficient data concerning the many varying causes of fluctuation.

There is, no doubt, much unpublished information possessed by many of the larger flood-control organizations and others, that is used privately, but which is of potential value to the profession generally. Some of these data are issued from time to time in local publications, while many are retained for aid in the solution of local problems, another portion being still in the experimental stage.

Liberal contributions of this information, coupled with a systematic collection by the Society of existing available data, could be made the first step in a more thorough analysis of Factor C with the view of establishing tentative tables of general value to the profession.

Such tables could not be final; experimentation will be continually needed in the future; but a more concerted effort of the profession in analyzing data on the run-off coefficient would not only be of temporary worth, but its results should point the way to better experiments. To this general fund of information the reader is referred for values of the run-off coefficient. Reference is also made to the conclusions herein under the heading, "Factor C, The Run-off Coefficient".

At present, average values of C for a given water-shed are arrived at by many through comparisons with experimental values obtained on areas of somewhat similar characteristics and size. When a water-shed is considered in parts the average, C, is, of course, the weighted average of separate divisions, for example, $C = \frac{a_1 C_1 + a_2 C_2 \dots + a_n C_n}{a_1 + a_2 + a_3 \dots + a_n}$, in which, a_1, a_2, a_3, ... a_n, represent individual areas composing the water-shed.

When information on the variation of C with time and intensity is possessed, it may be considered advisable to divide the area into approximate time divisions. For areas very irregular in regard to the factors, F and S, the divisions for Factor C may be correlated with those for the other factors.

It should be evident that the increase of the run-off coefficient with the time (as at present practiced by many of the users of the rational method) can be predicated only on the assumption of a water-shed, the surface of which is not in a saturated condition when the maximum run-off producing intensity occurs.

The assumption of a saturated surface condition is, of course, conducive to the maximum run-off. The question naturally arises, when may the surface be considered saturated? Much good information on this point has been given by Ivan E. Houk, M. Am. Soc. C. E. In this connection the chapter of his report entitled, "Rainfall and Run-Off Rates on Saturated Soils",[11] is of particular interest.

It is also worthy of note that proper assumptions on degree of previous saturation pursuant to the use of the rational method cannot be made without due consideration of the manner of making the rainfall curve the use of which is contemplated. The intensity-time-frequency curves in present use (as evidenced by current publications and textbooks) are platted from data selected from portions of storms, in such manner that their use presupposes that precipitation may be expected to occur both before and after the run-off producing intensity represented by a given ordinate.

It seems reasonable, therefore, that in attempting to estimate the probable maximum run-off for the wet season of the year (at which time the storm predicted may be expected to follow closely on the heels of previous rains) through the use of such curves, a saturated surface condition should be assumed for the usual water-shed, the surface of which is composed of ordinary soil, or combinations of soil and impervious materials.

Analysis of Experimental Data.—Equation (39), following, is derived for the purpose of facilitating the analysis of experimental data, leading to the compilation of tables (or diagrams) of Factor C.

For evolving the formula, retention is considered as subdivided into three main parts, namely, evaporation, absorption, and storage.

Evaporation, which herein is meant to include transpiration, is not a great consideration in the process of estimating instantaneous run-off, and usually could be neglected without serious error. The loss to run-off through absorption is large when the soil is dry, and is considerable for saturated soils. Storage, as used in the formula, is intended to represent the loss to run-off of the total precipitation falling in depressions, cavities, etc. Thus, the term includes percolation, when the precipitation is lost in this manner.

---

[11] "Rainfall and Run-Off in the Miami Valley," by Ivan E. Houk, Technical Repts., Miami Conservancy Dist., Pt. VIII, p. 119.

It is significant that the combined rates of evaporation and absorption may be represented in the formula by a single symbol, since they are not altered materially by a change in intensity. The rate of storage, on the other hand, will be greater for an increased intensity. Since all practical areas contain some storage capacity, this fact (in addition to the consideration of evaporation), explains why experimental results never show unity for Factor C, even for a saturated impervious surface.

For a given area, let m = percentage of precipitation, i, that is being stored. Then $m\,i\,A$ = rate of storage, in cubic feet per second, and $i\,A - m\,i\,A$ = rate of run-off, having deducted storage alone, in cubic feet per second. Of the remaining water, evaporation and absorption are taking toll.

Let z = rate of absorption plus rate of evaporation, in cubic feet per second per acre. Then $z\,A - m\,z\,A$ = cubic feet per second being absorbed and evaporated; and, therefore, $(i\,A - m\,i\,A) - (z\,A - m\,z\,A) = i\,A - z\,A + m\,z\,A - m\,i\,A$ = actual run-off, in cubic feet per second.

Substituting this expression for Q in Equation (1), there results: $C\,i\,A = i\,A - z\,A + m\,z\,A - m\,i\,A$, and,

$$C = 1 - \frac{z - m\,z + m\,i}{i} = \left(1 - \frac{z}{i}\right)(1 - m) \qquad (39)$$

In connection with Equation (39), reference should be made to Fig. 6. The curves thereon not only transform the very valuable experiments of Mr. Houk into a form suitable for use in the rational method, but also tend to illustrate the usefulness of Equation (39).

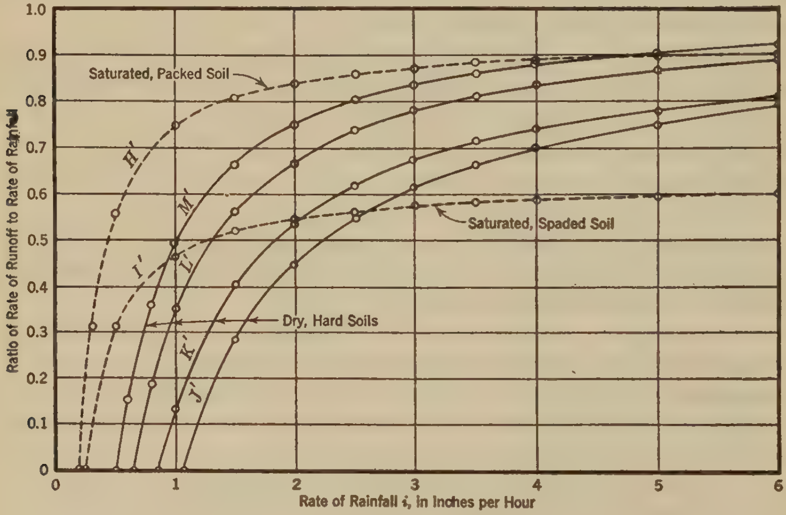


FIG. 6.—VALUES OF C FROM EXPERIMENTATION ON ELEMENTARY AREAS

The intercept on the abscissa axis (or the value of intensity when Factor $C = 0$) is represented by the letter, b, in Mr. Houk's report, and by z in Equation (39). There is no letter designation in the Houk report to indicate the percentage of storage, m, of the formula.

Values of m and z for the curves, H', I', J', K', L', and M', respectively, are shown in Table 7.

TABLE 7.—VALUES OF m AND z FOR CURVES, H', I', J', K', L' AND M' OF FIG. 6

Curves	m	z
H'	0.066	0.20
I'	0.375	0.25
J'	0.048	1.05
K'	0.048	0.87
L'	0.0	0.67
M'	0.0	0.52

Calculations for the values in the line, H', will illustrate. From the straight-line equation, $y = 1.07\,x + 0.20$ (for Line H of the report), derive the value of $\frac{x}{y} = \frac{y - 0.20}{1.07\,y} = \left(1 - \frac{0.20}{y}\right)\frac{1}{1.07}$. Since $\frac{x}{y}$ is the equivalent of Factor C of Equation (39), $\frac{1}{1.07} = 1 - m$, and, $m = 0.066$ (see Table 7).

It should be observed (see Table 7), that some storage, as defined in assumptions for the derivation of Equation (39), is recorded (although the areas represented were very small) for all the curves with the exception of L' and M'.

The values of m for Curves H', J', K', L', and M' are small because the soil of the areas experimented upon was packed. It seems that the extremely high value for m of Curve I' was caused by spading the soil, thus permitting a certain percentage of the precipitation (regardless of its intensity) to enter cavities directly. In such case, the water due to a certain intensity and time of sprinkling would merely fill the cavities. Additions above this quantity would still be lost because of the nature of the subsoil and the head developed in the cavities.

SUGGESTIONS FOR USE OF FORMULAS

Method No. 1.—The first method involves seven distinct steps, as follows:

1.—Decide on the type of rainfall curve, and reduce Equation (24) accordingly:

- (*a*) In the absence of rainfall data and for approximate estimates, use Equation (28) or Equation (29).
- (*b*) Establish H.
- (*c*) Determine R_H.

2.—Determine A and locate the main channel of flow (if necessary do this by trial, using approximate values for nucleus, C, F, S, P, etc.). Establish L, and $\frac{L}{W}$.

3.—Determine average values for Factors C, F, and S, for the water-shed, being guided by admonitions in the preceding parts of the paper and judgment concerning the requirements of the particular problem.

4.—Determine C', A', L', $\frac{L'}{W'}$, and $\frac{A}{A'}$; assign a time, t', to A', and calculate Q' from $Q' = C' i' A'$. (When the use of Table 3 is contemplated, or when the assumption is that the storm is of uniform intensity for the time of concentration of the water-shed, i' should be the approximate intensity of the water-shed, and t' should be based on this intensity.

When the use of Table 4 is contemplated, or when it is desired to take advantage of the factor of safety rendered by the use of a rainfall curve of the type of Equation (3) in the manner ordinarily employed in the detail process of the rational method, $i' = \frac{K}{(t')^{0.5}} = R_H \frac{(60\,H)^{0.5}}{(t')^{0.5}}$ (for t', in minutes).

5.—Obtain $v' = \frac{L'}{t'}$, for t', in seconds, and V' = velocity of Q', based on average values of F and S for the water-shed, $= \frac{F^2}{S^{\frac{1}{8}}} s^{\frac{1}{2}} (Q')^{\frac{1}{4}}$. Determine $\frac{v'}{V'}$ and correct this value of P_1 in Fig. 3, giving P'.

6.—With the corrected value of P' enter Table 3, or Table 4, in the proper columns for $\frac{L}{W}$ and $\frac{A}{A'}$, being guided by Fig. 2 and by guide lines for the manner of concentration in Fig. 4, finding P.

7.—Substitute the values of Factors C, A, R_H, S, P, F, and L in the reduced formula and solve for Q. It should be remembered that:

(*a*) Length L includes L' of the nucleus.
(*b*) The average, C, includes consideration of C' of the nucleus.
(*c*) The average slope for use in formulas is the average slope of the main channel of flow, exclusive of the nucleus.
(*d*) The average, F, is the average value of F for the main channel of flow, exclusive of the nucleus.

This method offers opportunity for varying the effect of the inlet area, or nucleus, in much the same manner as may be followed in the detail process of the rational method. As has been shown, the assignment of a value for P' on a given nucleus is the equivalent of allowing so much inlet, or initial, time. The method will be found valuable, depending on the water-shed and the purpose in view. For instance, it may be considered advisable to allow a certain lapse of time to prepare a regular water-shed to begin shedding the water by allowing for storage in small irregularities of surface, leaves, vegetation, etc. (this, however, is a special consideration), or, again, it may be of advantage to use Method No. 1, when the types and slopes of channels through which the inlet areas contribute, differ radically from that of the main channel of flow.

Method No. 2.—It should be borne in mind, however, that Method No. 1, is not the only manner in which the formulas may be found useful. Broadly speaking, they may be used in the same way as the ordinary empirical formulas, with the added advantage of permitting the engineer to allow for variables, which the use of existing formulas prohibits (see the heading, "Inadequacy of Empirical Formulas").

When used in this manner the length, L, should be the full distance from the most remote part of the water-shed to its outlet, and Factors S and F should represent average values for the full length.

Furthermore, Factor P should be chosen from the column of Table 3 headed by $P' = 0.5$, and under the section where $\frac{A}{A'} = 262\,144$ (approaching infinity, see the statement concluding the heading, "Method of Arriving at Values of Factor P"). The value of $\frac{L}{W}$ for the water-shed, and the manner of concentration, should be considered, of course, in arriving at the value of P.

This method is short, but, if proper judgment is exercised in selecting values of the various factors of the formula used, it affords a means of arriving at a quick approximate Q and, consequently, the time of concentration of a given water-shed for the assumptions. Having computed Q, the intensity is found from Equation (1), and the time of concentration is determined by referring the intensity to the rainfall curve on which the formula used is based.

Indeed, this method may be used in all ordinary cases without recourse to Method No. 1, admitting a small error, which is less on the average than the automatic error of the detail process mentioned under the heading, "Use of Rainfall Curve" (see, also, "Examples: Remarks on Example 10").

After the time has been found, simply add or deduct the difference in inlet time, referring the new time to the rainfall curve for the intensity to be used in Equation (1).

It should be evident that the first solution by this method entails the assumption that the water is ready to begin concentrating immediately, the time of the inlet area, or nucleus, being contained in the total time of the water-shed as rendered by average values of the various factors of the formula for the entire area. Any increase (or decrease) in the inlet time above (or below) this assumption may be applied as suggested herein.

Special Case.—Attention should be called to a special case sometimes encountered in the rational method of computing run-off. In mountainous territory it is often found that the higher altitudes of a given water-shed may reasonably be expected to receive a greater intensity for an assumed period of frequency than the lower portions. In attacking the solution of this problem the territory may be divided into zones, to each of which is assigned the probable R_H that may be expected to occur. Thus, where R_1 represents the probable average intensity over any one zone throughout a period of 1 hour (for a water-shed divided into three parts), the zone of highest altitude may be assigned a value, $R_1 = 3$ in., the middle zone, $R_1 = 2.50$ in., and the lowermost zone, $R_1 = 2$ in. per hour.

In the detail process of the rational method the problem is sometimes approached as follows: On the diagram of rainfall curves, that curve representing the assigned intensity requirements (such as $R_1 = 3$ in.), is chosen; this curve is followed until all the individual areas of the first zone have contributed; then transfer is made to the required curve for the next zone, such as $R_1 = 2.50$ in. per hour (without making reduction at the point of transition), the second curve being used as the first. In this manner the entire water-shed is covered. The method is an approach to a reasonable solution for the conditions assumed. The method results in the use of an average rainfall curve for the several zones.

In using the formulas and methods herein outlined the average value of R_H may be obtained for the water-shed through weighting the individual zone values of R_H by the respective zone areas. The average value of R_H is to be used, of course, with the rainfall curve to which it belongs.

Other Coefficients.—It is unfortunate that more information is not available concerning the distribution of rainfall especially over the larger areas. It is possible that more accurate information on this point could be utilized through three possibilities, as follows:

(*a*) Alteration of the frequency periods (or values for a given frequency) of the time-intensity-frequency curves in present use.
(*b*) Coefficients of distribution.
(*c*) The use of only a part of a given drainage area instead of the whole.

The writers believe that it is customary at present among American engineers to use rainfall curves as if the intensity were uniform over the entire area throughout the time of concentration. This practice (in the absence of more complete information on the distribution of rainfall) is based, no doubt, on the common observation that rains of lighter intensity and longer duration (required for consideration of the larger areas) are likely to be steadier and of wider distribution than those rendering higher rates of precipitation, which are more generally applicable to the smaller areas.

The time-intensity-frequency curves in present use are usually developed from the records of individual gauges. In this case it would be unwise to assume that the intensity designated by a certain ordinate on a curve represents the rate of precipitation at the eye or focus of the storm; or that it should be used to indicate the maximum rate within an area on which the intensity is unequally distributed at a given moment.

Coefficients based on this assumption, therefore, should not be used as direct multiple factors in reducing the run-off results that may be obtained through the use of the curves developed from the records of individual gauges.

As the writers view the problem the following procedure (in the light of present and future information) should be followed:

1.—Efforts should be made to ascertain whether or not the intensities rendered by curves in present use may reasonably be applied over the entire area.

2.—If such intensities can not be applied over the entire area, then endeavor should be made to apply the information through the foregoing suggested possibilities, (*a*), (*b*), or (*c*).

The "coefficient of retention" is accounted for in the run-off coefficient as used by American engineers. (See the heading, "Factor *C*, The Run-Off Coefficient".)

The "coefficient of retardation" is defined as the ratio of the contributing area to the total drainage area when the maximum discharge is caused by a storm which lasts for a lesser length of time than the time of concentration of the total drainage area. This possibility should be taken into account, especially for some areas, very irregular in regard to shape and physical characteristics.

Instead of using a coefficient, however, the problem should be solved by trial, use being made of that portion of the area rendering the maximum. The formulas herein (usually through Method No. 2), may be used advantageously for this purpose. Other writers have discussed this phase of the rational method.

Remarks.—The outstanding feature of the rational method is its conception of the time element in the estimation of maximum storm flows, affording, as it does, through the medium of its assumptions, a reasonable basis for predicting the probable intensities and frequencies of storms. It should be emphasized, however, that the solution of the run-off problem, although approached more easily through the special assumptions of the rational method, is still indeterminate. This statement may be understood more easily when it is recognized that there is no conceivable way of arriving at a perfect solution under the assumptions, because it is necessary to approach accuracy by trial.

The detail method is only an approach. For instance, at the beginning of the process, it is necessary to assign a time for the concentration of the initial area. This time, among other considerations, depends on the intensity. Since the assumption is that for a given water-shed the intensity shall be uniform over the entire area throughout its time of concentration, and, since its value cannot be known in advance, the assignment of the inlet time may be made only as an approach to accuracy under the assumption. Likewise, in the assignment of the run-off coefficient both to the initial area and the remainder of the water-shed (since its value depends on the intensity), accuracy can only be approached by trial. Therefore, it has not been the common practice of users of the detail rational method to consider the effect of intensity on either the inlet time or the value of the run-off coefficient.

Intelligent use of the formulas, requires not only a familiarity with the foregoing derivations and assumptions, but also a broad understanding of the run-off problem. The foregoing work, it is hoped, may serve as an aid in the solution of a difficult (and somewhat neglected) problem.

EXAMPLES

The following examples are intended to illustrate the application of the formulas.

Example 6.—Assume that for a given locality the intensity curve of the type, $i = \frac{K}{t^{0.5}}$ (Equation (3)), is considered adaptable, that, $R_H' = R_1$, and that the time period, H, is 1 hour. For this case, Equation (29) may be used. Let $R_1 = 2.0 =$ the expected rainfall intensity, in inches per hour, for a 1-hour period.

The study of a given area reveals that the water-shed area is somewhat similar in shape and manner of concentration to Type 18, Fig. 2. The dimensional data are: $A = 1\,294$ acres; $L = 20\,328$ ft.; $S = 10$ ft. per 1 000 ft.; and $C = 0.3$.

The main channel of flow is assumed to be a pipe with Kutter's $n = 0.013$. Hence, from Table 11 (Appendix II), $F = 6.63$.

Examination of the nucleus (or initial area) reveals that: $A' = 5$ acres; $L' = 700$ ft.; and $C' = 0.2$.

The following factors are estimated: $\frac{A}{A'} = 259$; $\frac{L}{W} = \frac{(20\,328)^2}{43\,560 \times 1\,294} = 7.3$; $\frac{L'}{W'} = \frac{(700)^2}{43\,560 \times 5} = 2.25$.

If the use of Table 4 is contemplated (or if it is desired to take advantage of the small factor of safety rendered by the use of a rainfall curve, Equation (3), as ordinarily followed in the detail process of the rational method), and a study of the nucleus calls for an assigned time, $t' = 10$ min., for this assumption; then,

$$Q' = C'\,i'\,A' = C'\,A'\,\frac{7.75\,R_H\sqrt{H}}{\sqrt{t'}} = \frac{0.2 \times 7.75 \times 2.0}{\sqrt{10}} \times 5.0$$
$$= 4.9 \text{ cu. ft. per sec.}$$

If that type of storm based on a uniform, or constant, intensity for the time of concentration had been assumed, it would have been necessary to base the assignment of t' on this assumption, using the approximate intensity for the water-shed; also, $Q' = C'i'A'$, wherein i' is the approximate intensity of the water-shed.

For the velocity ratio:

$$v' = \frac{L'}{t'} = \frac{700}{10 \times 60} = 1.17 \text{ ft. per sec.}$$

$$V' = \frac{F^2}{S^{\frac{1}{8}}}\sqrt{s}\,(Q')^{\frac{1}{4}} = \frac{(6.63)^2}{(10)^{\frac{1}{8}}} \times \sqrt{0.01}\,(4.9)^{\frac{1}{4}} = 4.87 \text{ ft. per sec.}$$

and,

$$\frac{v'}{V'} = \frac{1.17}{4.87} = 0.24 = P_1$$

Entering Fig. 3 with $\frac{L'}{W} = 2.25$, and $P_1 = 0.24$,

$$P' = 1.24 \times P_1 = 1.24 \times 0.24 = 0.3$$

Entering Table 4, with $P' = 0.3$, $\frac{A}{A'} = 259$, and $\frac{L}{W} = 7.3$, and guided by Figs. 2 and 4 to medium concentration for area, Type 18, $P = 0.51$. Hence, $\sqrt{\frac{P}{L}} = \sqrt{\frac{0.51}{20\,328}} = 0.005 = B$.

Substituting values for the various factors in Equation (29),

$$Q = 15\,(0.3 \times 1\,294 \times 2.0 \times 6.63 \times 0.005)^{1.1429}\,(10)^{0.2143}$$
$$= 1\,006 \text{ cu. ft. per sec.}$$

The intensity and time of concentration for the foregoing assumptions may be found from Equation (1), thus, $i = \frac{1\,006}{1\,294 \times 0.3} = 2.59$, and from Equation (26), $t = \frac{60\ (2.0)^2}{(2.59)^2} = 35.7$ min.

Example 7.—Assume that information on rainfall and the consideration of larger areas point to the use of a longer time period, or $H = 6$ hours; then, $R_H = R_6$. Again, assume that the rainfall curve, Equation (3), is adaptable. In this case Equation (28) may be used, or, substituting $H = 6$,

$$Q = 41.7\ (C\ A\ R_6\ F\ B)^{1.1429}\ S^{0.2143} \dots\dots\dots\dots \quad (40)$$

In $R_H = \frac{X}{H}$, or, $R_6 = \frac{X}{6}$, assume that $X = 4.8$ = the expected inches of rain for a period of 6 hours; then, $R_6 = \frac{4.8}{6} = 0.8$ in. per hour.

From a study of a given area it develops that the shape and manner of concentration are approximately midway between Types 16 and 17, Fig. 2. Furthermore, A = 500 sq. miles = 320 000 acres; A' = 8 acres; L = 223 600 ft.; L' = 1 200 ft.; S = 5 ft. per 1 000 ft.; $C = 0.2$; $C' = 0.25$; and $F = 5.7$. By estimate, $\frac{A}{A'} = \frac{320\ 000}{8} = 40\,000$; $\frac{L}{W} = \frac{(223\ 600)^2}{43\ 560 \times 320\ 000} = 3.6$; and $\frac{L'}{W'} = \frac{(1\ 200)^2}{43\ 560 \times 8} = 4.0$.

The use of Table 3 is contemplated. Assign an approximate average intensity for the water-shed, of 0.75 in. per hour. Examination of the nucleus points to the assignment of 15 min. for its time of concentration. Then, following Equation (1),

$$Q' = C'\ i'\ A' = 1.5 \text{ cu. ft. per sec.}$$

$$v' = \frac{L'}{t'} = 1.33 \text{ ft. per sec.}$$

$$V' = \frac{F^2}{S^{\frac{1}{8}}} \sqrt{s}\ (Q')^{\frac{1}{4}} = 2.08 \text{ ft. per sec.}$$

and,

$$\frac{v'}{V'} = 0.64 = P_1 = P'$$

(no correction is necessary since $\frac{L'}{W'}$ of the nucleus is approximately 4).

Entering Table 3 with $P' = 0.64$, $\frac{A}{A'} = 40\,000$; and $\frac{L}{W} = 3.6$, guided by Figs. 2 and 4, to approximately midway between medium and delayed concentration, P is found equal to 0.48 and $\sqrt{\frac{P}{L}} = 0.001465 = B$. Substituting values for the various factors in Equation (40),

$$Q = 41.7\ (427.5)^{1.1429}\ (5)^{0.2143} = 59\,740 \text{ cu. ft. per sec.}$$

The intensity by Equation (1) and the time of concentration by Equation (26) are, $i = 0.933$, and $t = 4.4$ hours, respectively.

Example 8.—Let the rainfall curve for a given locality be represented by $i = \frac{K}{t^{0.6}}$. Assume that $R_H = R_1$, or that $H =$ a 1-hour period. For this purpose Equation (24) reduces to:

$$Q = 28.3 \left(\frac{P}{L}\right)^{0.7059} (C\ A\ R_1)^{1.1765}\ F^{1.4118}\ S^{0.2647} \dots\dots\dots (41)$$

Now, assume that the values for the various factors are the same as those used in Example 6; then, by Equation (41) $Q = 1\,069$ cu. ft. per sec.

Example 9.—Let the rainfall curve be the same as in Example 8 and let $R_H = R_6$ and $H = 6$; then, Equation (24) reduces to:

$$Q = 100.2 \left(\frac{P}{L}\right)^{0.7059} (C\ A\ R_6)^{1.1765}\ F^{1.4118}\ S^{0.2647} \dots\dots\dots (42)$$

Substituting in Equation (42) the same factors used in Example 7, $Q = 62\,003$ cu. ft. per sec.

Remarks Concerning Examples 6, 7, 8, and 9.—The run-off, Q $(= 1\,069)$, for Example 8, may be approximated by referring the time, 35.7 min. (solved by the use of Equation (29)), to the rainfall curve,

$$i = \frac{K}{t^{0.6}} \dots\dots\dots\dots\dots\dots\dots\dots (43)$$

thus obtaining a new intensity for use in Equation (1).

In the absence of the curve, Equation (43), the intensity may be calculated directly from Equation (43) by substituting for K its value when $H = 1$ hour, and $R_H = R_1$; thus,

$$i = \frac{(60)^{0.6}}{t^{0.6}} \dots\dots\dots\dots\dots\dots\dots\dots (44)$$

This results in the value, $i = \frac{23.33}{35.7^{0.6}} = 2.73$. By Equation (1), the corrected run-off equals $0.3 \times 2.73 \times 1\,294 = 1\,060$ cu. ft. per sec. The percentage of accuracy is expressed by $\frac{1\,060}{1\,069} = 99.2$.

Likewise, the run-off, $Q = 62\,003$, for Example 9 may be approximated by referring the time, 264 min. (solved by the use of Equation (28)), to the curve of Equation (43) with the result that $i = 0.964$.

By Equation (1) the corrected run-off,

$$Q = 0.2 \times 0.964 \times 320\,000 = 61\,696 \text{ cu. ft. per sec.}$$

In this case the percentage of accuracy is $\frac{61\,696}{62\,003} = 99.6$.

The result to be expected from a given problem will not always be as close as the foregoing percentages indicate, since the shape, size, and manner of concentration of the area, will have some effect. However, when the adopted rainfall curve does not vary widely, the foregoing method may be used to give a quick approximate result, accurate enough for most practical purposes, for variations in the value of exponent, *e*, Equation (2), as encountered in common practice.

Similar transitions may be made, of course, to curves of other types, such as,

$$i = \frac{a}{b + t} \quad \ldots\ldots (45)$$

Example 10.—This example is shown for the purposes of illustrating the hydraulic construction of the formulas and making certain comparisons with the usual detail method.

Fig. 7 was selected from a topographical map and represents a small water-shed (rather thoroughly divided into individual areas by streets), with contour intervals of 5 ft. For comparative purposes it is necessary to place the tabling process and the formulas on the same basis, hence, the following assumptions are made arbitrarily:

(*a*) The rainfall curve is of the type of Equation (3), with $R_H = R_1 = 1.25$ in. per hour for a 1-hour period. Since $R_1 = \frac{K}{(60)^{0.5}}$,

$$K = (60)^{0.5} \times 1.25 = 9.69$$

or,

$$i = \frac{9.69}{t^{0.5}} \quad \ldots\ldots (46)$$

(*b*) Circular pipe (Kutter's $n = 0.013$) is used throughout the main, or time-giving, channel of flow.

(*c*) The run-off coefficient, C, is equal to 0.4 throughout.

Area No. 1 of Fig. 7 is chosen as the initial area for the tabling process shown in condensed form in Table 8. It is further assumed that the inlet Area No. 1 (a small water-shed) concentrates in the manner shown for Type 3, Fig. 2. For the initial area: $A = 8$ acres; $L = 1\,200$ ft.; $S = 3$ (for a fall of 3.6 ft. in 1 200 ft.); $C = 0.4$; $R_1 = 1.25$; and P (from Table 4, making use of "Suggestions for Use of Formulas, Method No. 2,") $= 0.53$. Using Equation (29) (due to the foregoing assumption for the rainfall curve): $B = \sqrt{\frac{P}{L}} = 0.021$,

and,

$$Q = 15\ (0.4 \times 8 \times 1.25 \times 6.63 \times 0.021)^{1.1429}\ (3)^{0.2143} = 9.8 \text{ cu. ft. per sec.}$$

By Equation (1) then, $i = 3.06$, and by Equation (26),

$$t = \frac{60 \times 1.25^{+2}}{3.06^2} = 10 \text{ min.}$$

For the initial area, 10 min. represents a value that would be found for its time of concentration (on the foregoing assumptions) if it were tabled down from an infinitesimal beginning by the detail process. That value is used to

start the tabling process of Table 8, using Fig. 7. The four water-sheds selected are numbered 1, 2, 3, and 4 on Table 8 and are represented, respectively, by the total areas above Points 1, 2, 3, and 4, of Fig. 7. The velocities in Table 8 were calculated by the use of Kutter's formula.

Comparison of Times of Concentration and Run-off by Different Methods.—The time and run-off, determined by five processes, are arranged for comparison in Table 9. The explanation of this table may be itemized in the form of eight remarks, as follows:

(1) Values in Columns (2) and (3) of Table 9 were selected from Table 8.

(2) Those in Columns (4) and (5) were calculated by the use of Equation (29). The computations for Water-Shed No. 2 (Fig. 7) will illustrate the process.

The following were selected from Table 8: $A = 1\,653$ acres; $L = 17\,115 + 1\,200$ (length in initial area $= 1\,200$ ft.) $= 18\,315$ ft.; $S = \dfrac{\text{Total fall}}{\text{Total length}} = \dfrac{68.40 + 3.60}{18\,315} = 3.93$ ft. per 1 000 ft.; $P = \dfrac{v}{V}$; $v = \dfrac{L}{t} = \dfrac{18\,315}{60 \times 42.98} = 7.1$; V (using Kutter's formula, $n = 0.013$, for circular pipe, $S = 3.93$, and $Q = 978.5$) $= 13.1$; $P = \dfrac{7.1}{13.1} = 0.54$; and $\sqrt{\dfrac{P}{L}} = 0.00543 = B$. Solving,

$$Q = 15\,(0.4 \times 1\,653 \times 1.25 \times 6.63 \times 0.00543)^{1.1429}\ (3.93)^{0.2143}$$
$$= 971.5 \text{ cu. ft. per sec.}$$

Again, substituting correct values in Equations (1) and (26), respectively, $i = 1.469$ and $t = 43.4$ min.

(3) Columns (6) and (7), Table 9 were calculated by Equation (29) using Table 3, and following Method No. 2. All factors for use in Equation

FIG. 7.—ILLUSTRATING THE METHOD DESCRIBED IN EXAMPLE 10

(29) are the same as those used in the computations for Columns (4) and (5) of Table 9, with the exception of Factor P. This factor was selected from Table 3, corresponding in position to the values chosen from Table 4 for Columns (4) and (5) of Table 9.

(4) Columns (9) and (10) were obtained by "tabling" Fig. 7 in detail, with the same assumptions and data as in Table 8, except that 20 min. were used for the time of the initial area. The table is not reproduced in this paper.

(5) Columns (11) and (12) were calculated by use of Equation (29) and Table 4 and by following Method No. 1, assuming a 20-min. inlet time on the initial area.

(6) It may be noted that Q_a and Q_b, as well as Q_1 and Q_2, in Table 9, are practically equal for a given water-shed. This fact indicates the correctness of the construction of Equation (29) which was reduced from Equation (24). Since the detail process and the equation were placed on the same basis in each case, it shows Methods Nos. 1 and 2 to be logical in approach for the assumptions, and serves to testify to the accuracy of the particular value of 6.63 for pipe with Kutter's $n = 0.013$, and (to a certain extent) the construction of Table 4. The construction of Table 9 was not, however, mainly for the purpose of proving the Points 1 to 5. The logic in the derivation of the formulas is contained in this paper under the proper headings, and the methods of arriving at Factors P and F are fully explained.

Values Q_a, Q_b, Q_1, and Q_2 contain the error mentioned herein under the heading "Use of Rainfall Curve". Values Q_c do not contain this error, being evolved through the use of Table 3 with the formula. Values of the ratio, $\frac{Q_b}{Q_c}$, show the possible magnitude of the error rendered by the detail process (or Table 4) for these particular water-sheds and the assumptions therefor and the rainfall curve used.

Values t_c and Q_c (Columns (6) and (7) of Table 9) are not intended to represent exactly the actual times and quantities for the respective water-sheds, which would obtain in an economically designed storm drain system constructed of closed conduit. If the assumptions of the rational method are strictly adhered to, it must be assumed that, in such systems, the storm which produces the quantity for a given water-shed, is not of sufficient intensity to fill the conduit above the outlet entirely. To allow for this condition with the formula through the use of Table 3 a higher average value of Factor F should be selected from Table 11 (Appendix II). However, the ratio, $\frac{Q_b}{Q_c}$, does represent closely the actual error which would occur in open channel work.

(7) It is interesting to compare Values t_a and t_1 (Columns (2) and (9) of Table 9). Both sets of values resulted from the detail "tabling" process, the former on the assumption of 10-min., and the latter of 20-min., initial inlet time. The difference in inlet times used is 10 min. If instead of using the values, t_1, this difference is added to the values, t_a, the error in Q is

measured by the ratio, $\frac{\sqrt{t_1}}{\sqrt{t_a + 10}}$ (since, for the rainfall curve used, Q varies inversely as the square root of t). This error, like the ratio, $\frac{Q_b}{Q_c}$, may be expected to vary somewhat for differences in inlet times assumed, water-sheds, and rainfall curves. It will be smaller (on the average) than $\frac{Q_b}{Q_c}$ for all ordinary additions.

(8) Remarks (6) and (7) indicate that in all cases Method No. 2 may be used to approximate run-off, the error in result being well within the automatic error due to the ordinary detail "tabling" process.

A better understanding of the reason for this small error may be had from the following illustration, which also indicates how greater refinement may be attained. Referring to the solution of Water-Shed No. 2 (see "Remark (2)"), $t_b = 43.4$ min.; and $Q_b = 972$ cu. ft. per sec. (10-min. inlet time).

If 20-min. inlet time has been used, the time would have been, approximately, $t_b + 10$, or 53.4 min., and the total run-off, by Equation (1), will be

$$Q = 0.4 \times \frac{9.69}{(53.4)^{0.5}} \times 1\,653 = 877 \text{ cu. ft. per sec.}$$

The maximum velocity (for this second consideration) on the average slope, and F, is: $V = \frac{F^2}{S^{\frac{1}{8}}} s^{\frac{1}{2}} Q^{\frac{1}{4}} = Q = \frac{(6.63)^2}{(3.93)^{\frac{1}{8}}} (0.00393)^{\frac{1}{2}} (877)^{\frac{1}{4}} = 12.65$ ft. per sec. The average velocity equals $v = P\ V = 0.54 \times 12.65 = 6.83$. Finally, $t = \frac{L}{v} = \frac{18\,315}{6.83} = 2\,682$ sec. $= 44.7$ min.

This is an approximation of the time of concentration due to the smaller average quantity of water running. Furthermore, 44.7 + 10 min. = 54.7, which closely approximates the 54.9 min. resulting from the 20-min. inlet "tabling".

Reminder.—The solution of the run-off problem, through the medium of any assumptions, must be one of trial. The assignment of an inlet time (if used) and the run-off coefficient depend on the intensity. Since the intensity must be anticipated, a second solution may be necessary when the intensity varies sufficiently from the assumptions. It is hoped that future experimentation on the run-off coefficient will furnish more reliable data for selection.

APPENDIX I

NOMENCLATURE FOR PART II

The following nomenclature, in brief, is used:

A = area of water-shed, in acres.
A' = area of initial area, or nucleus, in acres.
a = area of water-shed, in square feet.

$B = \sqrt{\frac{P}{L}}$.
C = coefficient representing the ratio of the rate of run-off to the rate of rainfall.
C' = coefficient of run-off for initial area, or nucleus.
c = constant in Chezy formula, $v = c\sqrt{r\,s}$.
e = a positive fractional exponent of time, t, in Equation (2).
f = correction factor (see Fig. 3).
F = constant, depending on shape and condition of main channel of flow; $F = N\,S^{\frac{1}{16}}$.
H = a given period of rain, in hours, $R_H = \frac{X}{H}$.
i = intensity of rainfall, in cubic feet per second per acre, or, approximately, in inches per hour.
i' = average intensity on initial area, or nucleus.
J = constant $= \frac{N}{r^{\frac{1}{4}}}$.
K = constant in Equation (2) $= i\,t^e$.
K' = constant.
K'' = constant.
l = any length, in feet.
L_1, L_2, L_3, etc. = subdivisions of l.
L = length, in feet, which water must traverse in running from the most remote portion of the water-shed to its outlet.
L' = length, in feet, which water must traverse in running from the most remote portion of the nucleus to its outlet.
M and M' = constants.
m = percentage of precipitation, i, being stored.
N = constant $= \frac{(c\sqrt{r})^{\frac{1}{2}}}{Q^{\frac{1}{8}}} = \frac{F}{S^{\frac{1}{16}}}$.
P = constant, depending on shape of area of water-shed and its manner of concentration, $P = \frac{v}{V}$.
$P_1 = \frac{v'}{V'}$.
P' = constant, depending on beginning nucleus, = corrected P_1.
Q = rate of run-off, in cubic feet per second.
Q' = rate of run-off from nucleus, in cubic feet per second.
R_H = average rainfall intensity, in inches per hour, for a period of H hours, $R_H = \frac{X}{H}$.
r = hydraulic radius in $v = c\sqrt{r\,s}$; also, rate of retention.
s = slope, or fall, in feet per foot, in length of main channel of flow.
S = fall, in feet per 1 000 ft. of main channel of flow; $S = 1\,000\,s$.
t = time of concentration of water-shed = time required for the water to travel from the most remote portion of the water-shed to its outlet.
t' = time of concentration of nucleus.
v = average velocity of water, in feet per second, in traversing the length, L. $v = \frac{L}{t}$, or, hydraulically, $v = c\sqrt{r\,s}$.

v' = average velocity of water, in feet per second, in traversing the length, L'. $v' = \frac{L'}{t'}$.

V = velocity of Q at outlet of water-shed, based on average values of F and S for the water-shed.

V' = velocity of Q' based on average values of F and S for the water-shed.

$W = \frac{a}{L} = \frac{43\,560\,A}{L}$.

$W' = \frac{43\,560\,A'}{L'}$.

X = inches of rain for a period of H hours; $R_H = \frac{X}{H}$.

z = rate of absorption plus rate of evaporation, in cubic feet per second per acre.

APPENDIX II

Method of Calculating Values of N and F

Begin with, say, a 14 by 7-ft., open, rectangular channel with an area of 98 sq. ft., and an hydraulic radius of 3.50. Next, select from any reliable set of hydraulic tables (showing velocities for varying values of the hydraulic radius, Kutter's n, and the slope) the velocity for an hydraulic radius of 3.50 in the column of $s = 0.01$ (or $S = 10$), with Kutter's $n = 0.013$. This will be $V = 26.25$. Calculate $Q = 98 \times 26.25 = 2\,572.5$.

For $s = 0.01$, $c\sqrt{r} = 10\,V = 262.5$, and $\left(c\sqrt{r}\right)^{\frac{1}{2}} = 16.20$. Substituting this value and the value, $Q = 2\,572.5$, in Equation (18), $N = 6.07$. This factor may be calculated for varying values of Kutter's n in the foregoing manner and placed on a line opposite an open rectangular channel, as in Table 10. This table was prepared by slide-rule computations for the purpose of illustrating the method.

It was shown that Equation (18) applies for a given shape and condition of channel. Having determined N for the 2 by 1 (width by height) open conduit, its value may be calculated for other shapes (for the small change in the hydraulic radius due to shape alone) by letting $N \propto r^{\frac{1}{4}}$. Thus, having assumed an area of 98 sq. ft for a 2 by 1 open conduit, calculate the relative r and $r^{\frac{1}{4}}$ for various shapes of channels using an area of 98 sq. ft., and arrange them in tabular form for reference. Then, since $N \propto r^{\frac{1}{4}}$, $N = J\,r^{\frac{1}{4}}$, or,

$$J = \frac{N}{r^{\frac{1}{4}}} \qquad \text{(47)}$$

the corresponding values of N for any shape of channel may be calculated, and the table expanded. For instance (using $N = 6.07$), $J = \frac{N}{r^{\frac{1}{4}}} = \frac{6.07}{1.366} = 4.44$.

Then, selecting any shape, such as circular pipe, with $r^{\frac{1}{4}} = 1.292$, $N = J\,r^{\frac{1}{4}} = 4.44 \times 1.292 = 5.74$.

The value of $J = 4.44$ may be used for calculating N for other shapes under Kutter's $n = 0.013$. In like manner the value of J obtained through the use of N, under other values of Kutter's n, may be used for calculating N for various shapes.

Having calculated the values of N for $S = 10$, values of F may be calculated. It was shown, in introducing Equation (21), that,

$$N = \frac{F}{S^{\frac{1}{16}}} \quad \text{.........................} (48)$$

Therefore, using $S = 10$, $N = \dfrac{F}{(10)^{\frac{1}{16}}}$, or $F = N\,(10)^{\frac{1}{16}}$.

Thus, having found the values of N under an assumed S, the factor, F, may be readily calculated and arranged as shown in Table 11. This table, showing values of F for channels of varying shape and condition, may be used in its present form, or may be expanded for use in general hydraulic work.

For N in Equation (18) substitute its value in Equation (48) and simplify, thus,

$$\sqrt{r} = \frac{F^2}{S^{\frac{1}{8}}}\,Q^{\frac{1}{4}} \quad \text{.......................} (49)$$

In turn, substituting this value of $c\,\sqrt{r}$ in Equation (13): $v = c\,\sqrt{r\,s} = \dfrac{F^2}{S^{\frac{1}{8}}}\,s^{\frac{1}{2}}\,Q^{\frac{1}{4}} = 0.03162\,F^2\,S^{\frac{3}{8}}\,Q^{\frac{1}{4}}$, or,

$$v = 0.4217\,F^2\,s^{\frac{3}{8}}\,Q^{\frac{1}{4}} \quad \text{.....................} (50)$$

Thus, for a given run-off, Q, the approximate velocity may readily be computed for any definite shape with an assigned Kutter's n.

Since the velocity varies directly as F^2, Table 11 may also be used as a handy guide to the efficiency of relative shapes for a given Kutter's n.

Statement.—Heretofore, it has not been customary to allow for variation in the shape and condition of the main channel of flow in run-off formulas. The writers, however, have considered it well worth while to do so. In order to devise a practical working table of variations it was necessary to select, carefully, the velocity formula which could be used most advantageously for the purpose. The Kutter formula for c in $c\sqrt{rs}$ has been, and is at present, used very widely in hydraulic computations. It was chosen because of its general application to all shapes and conditions of channels. The exponential form for the combination of the Kutter and Chezy formulas (Equation (50)) affords a very practical means of arriving at a rational time of concentration (which is based on average velocities) of a given water-shed. Considering the inexact nature of the run-off problem, it is close enough for all practical purposes.

Some more recent experimentation has been done, which indicates that Kutter's formula is somewhat in error for certain shapes of section. The Scobey formula for concrete pipe flowing full is one of the best known. This formula is:

$$Q = 0.00546\, C_s\, d^{2.625}\, H^{0.5} \qquad \text{.....................(51)}$$

or,

$$v = C_s\, d^{0.625}\, H^{0.5} \qquad \text{.......................(52)}$$

in which, Q is the discharge, in cubic feet per second; v, the velocity, in feet per second; C_s, Scobey's coefficient; d, the diameter, in inches; and H, the friction head per 1 000 ft.

For comparative purposes it may be of interest to reduce the Scobey formula, showing the velocity in terms of C_s, H, and Q. From Equation (51), $d^{2.625} = \dfrac{Q}{0.00546\, C_s\, H^{0.5}}$, and,

$$d^{0.625} = \frac{Q^{0.2381}}{0.2892\, C_s^{0.2381}\, H^{0.119}} \qquad \text{...................(53)}$$

Substituting Equation (53) in Equation (52),

$$v = 3.459\, C_s^{0.7619}\, H^{0.381}\, Q^{0.2381} \ldots\ldots\ldots\ldots (54)$$

Using the nomenclature of this paper, and replacing H in Equation (54) by S,

$$v = 3.459\, C_s^{0.7619}\, S^{0.381}\, Q^{0.2381} \ldots\ldots\ldots\ldots (55)$$

Comparing Equation (55) (which is the Scobey formula reduced to like terms) with the exponential form of the Kutter-Chezy formula (Equation (50)), it may be seen that the exponents of S and Q do not differ greatly.

This difference will be of less consequence in its effect on run-off calculations, as may be shown by substituting the value for v, shown in Equation (55), in the formula, and following the same method of reduction as outlined in connection with Equation (14):

$$Q = (3\,600\; H)^e\; C\; A\; R_H \frac{v^e}{L^e} \ldots\ldots\ldots\ldots (56)$$

Factor H in Equation (56) is not to be confused with the H in the Scobey formula (Equation (51)), which was replaced by S.

For v in Equation (56) substitute Pv, in which, v is given in Equation (55); thus

$$Q = (3\,600\; H)^e\; C\; A\; R_H \frac{[P\,(3.459\, C_s^{0.7619}\, Q^{0.2381}\, S^{0.381})]^e}{L^e}$$

or,

$$Q = (12\,452.4\; H)^{eq} \left(\frac{P}{L}\right)^{eq} (C\; A\; R_H)^q\; C_s^{0.7619\,eq}\; S^{0.381\,eq} \ldots\ldots\ldots (57)$$

in which, q has been substituted for the exponent, $\dfrac{1}{1 - 0.2381e}$, for simplicity.

Equation (57) may be compared with Equation (24). It may be reduced to a special form by letting $e = 0.5$, in which case, $q = \dfrac{1}{1 - 0.1191} = 1.1352$, and,

$$Q = 210.9\; H^{0.5675} \left(\frac{P}{L}\right)^{0.5675} (C\; A\; R_H)^{1.135}\; C_s^{0.4324}\; S^{0.2162} \ldots\ldots (58)$$

Substituting $\sqrt{\dfrac{P}{L}} = B_1$ and $\sqrt{S} = D$,

$$Q = 210.9\; H^{0.5675}\, (C\; A\; R_H\; B_1)^{1.135}\, (C_s\; D)^{0.4324} \ldots\ldots\ldots (59)$$

and when $H = 1$ hour,

$$Q = 210.9\; (C\; A\; R_1\; B_1)^{1.135}\, (C_s\; D)^{0.4324} \ldots\ldots\ldots\ldots (60)$$

Equations (58), (59), and (60) may be compared with Equations (27), (28), and (29), respectively. It may be noted that the difference in exponents is small and that a certain compensating effect takes place between the exponents for S and those for the other factors.

Equations (57), (59), and (60) may be used for run-off calculations by means of C_s values established by F. C. Scobey, M. Am. Soc. C. E. It is understood by the writers, however, that the Scobey formula for velocity is restricted to circular pipe flowing full. In this case Equations (57) to (60), inclusive, resulting from its use, are likewise restricted.

To illustrate further the direct applicability and correctness of the factors and formulas herein advocated, they are applied to the upper part of the Compton Creek water-shed, which lies immediately south of the City of Los Angeles. This area is divided into two main parts, the drainage channels of which converge near the lower end of the area. (Somewhat similar to Type 17, Fig. 2.) The western part of this area contains 16 731 acres and the eastern part, 12 361 acres.

Since the topography of both sides is similar, the West Channel, with a length of 64 600 ft., will control the time of concentration, since it is the longer.

Example 11.—Find the approximate time of concentration using a rainfall curve of the type of Equation (3).

Let R_1 = 1.50 in. per hour.
S = 2.07 ft. per 1 000 ft. from U. S. Topographical map. (Total fall, 134 ft.)
F = 6.5 (selected because part of the channel will be a closed rectangular box section running part full, and the remainder, pipe).

$$\frac{L}{W} = \frac{(64\ 600)^2}{43\ 560 \times 16\ 731} = 5.7.$$

Using Table 3, and Method No. 2, $P = 0.47$. Let $C = 0.4$; then $Q = 6\ 466$ cu. ft. per sec. by Equation (29); $i = 0.966$ by Equation (1); and $t = 144.7$ min. by Equation (26).

Example 12.—Find the approximate time of concentration which would result from the usual tabling process, with all data the same as Example 11 except that, $P = 0.55$ (selected from Table 4, Method No. 2); and, $F = 6.0$ (assuming all conduits running full). Then, $Q = 6\ 377$ cu. ft. per sec. by Equation (29); $i = 0.953$ by Equation (1); and, $t = 148.7$ min. by Equation (26).

Example 13.—Find the approximate time of concentration, using a rainfall curve of the type, $i = \frac{K}{t^{0.7}}$ and $C = 0.35$. All other data are the same as Example 11.

This solution could be made by the use of Equation (24) with proper exponents, using $e = 0.7$, but a close approximation may be made as follows: Using the time, 144.7 min. (Example 11), read the intensity from a curve of $i = \frac{K}{t^{0.7}}$ or calculate: $i = 0.81$ (see Equation (26)); $Q = 0.35 \times 0.81 \times 16\ 731 = 4\ 743$ cu. ft. per sec. by Equation (1); $V = 14.56$; $v = P\ V = 0.47 \times 14.56 = 6.84$; and $t = \frac{L}{v} = \frac{64\ 600}{6.84} = 157.3$ min.

The solution by means of Equation (24), with $e = 0.7$, gives $t = 160$ min. The difference between the times, 144.7 and 157.3, is due, of course, to the smaller average quantity of water running. In the same manner, approximations of the time of concentration may be found for any curve in use.

Example 14.—Find the approximate time of concentration with all data the same as Example 11 except that $C = 0.30$ and $F = 4.72$ (from Table 11, main channel, open earth, Kutter's $n = 0.035$, the bottom width is twice the depth, and the side slopes are 2 : 1.) Then, $Q = 3\,228$ cu. ft. per sec. by Equation (29); $i = 0.643$ by Equation (1); and, $t = 326$ min. by Equation (26).

DISCUSSION

LeRoy K. Sherman,[12] M. Am. Soc. C. E. (by letter).—In Part I, the authors have presented an excellent analysis of the variable factors affecting the rates of run-off. Engineers at the present time are generally agreed that the empirical run-off formulas, based simply on a function of the drainage area, are of very limited usefulness. In Part II, all the numerous factors involved in the rational method for determining run-off have been grouped into a rational formula. In the writer's opinion this is not desirable. The rational method as a procedure is preferable to the rational formula.

Although it is somewhat lengthy, the rational method is a simple process of computation. The various steps follow in logical sequence and can be readily visualized. The relative effects of the various factors and approximations are apparent. In a formula involving seven variables these relative effects are concealed. In the design of a system of storm drains, the time spent in computation by the rational method is time well spent, and the substitution of a formula merely as a time saver is not warranted.

Certain steps in the rational method may be diagrammed or tabulated—just as the authors have done—to serve as a useful guide. The writer has prepared and used several such diagrams applicable to the rational method.[13] Other engineers have presented similar diagrams.

In Example 7, the authors have applied their formula to a drainage area of 500 sq. miles. The main stream has a length of 42 miles. If this stream has a channel of regular and uniformly increasing cross-sections, without enlargements or constrictions, then the rational method as applied to storm drains may be used.

In general, natural streams draining large areas are irregular, with numerous enlargements and constrictions. On such streams the aforesaid rational method will not apply. This is because another variable (in addition to the seven mentioned by the authors) is involved; namely, the factor of pondage. In a stream with a flat slope, say, 1.5 ft. per 1 000, this pondage factor may reduce the peak rate of run-off 50 per cent.

For large drainage areas with unimproved natural channels the writer prefers the use of a rational method for determining run-off, based on the relation of an observed hydrograph to a known rainfall on the drainage area in question. This relation has been expressed as a coefficient by the Committee on Floods of the Boston Society of Civil Engineers[14] in its formula, $Q = C_r \sqrt{A}\, R$.

Francis Bates,[15] Assoc. M. Am. Soc. C. E. (by letter).—The authors present an original method for estimating storm-water run-off—based on fundamental conceptions and rational conclusions—which amplifies and refines the methods now in general use and should prove a valuable contribution to the literature heretofore published. The formulas are of sufficient flexibility to be made applicable to most of the rainfall curves, and contain factors neglected in the empirical formulas, but which, most certainly, are pertinent. They should prove very useful for determining the probable maximum flood at selected points, and for preparing preliminary cost estimates of drainage systems. The greater value of these refinements, however, should be in connection with the reduction of field observations made for the purpose of arriving at the correct values of the ratio of run-off to current rainfall, and, perhaps, the co-relating of the so-called values of *C* in the various empirical formulas.

[12] Pres., Randolph-Perkins Co., Chicago, Ill.

[13] See, *Municipal and County Engineering*, June, 1924.

[14] *Journal*, Boston Society of Civil Engineers, September, 1930.

[15] Cons. Engr., Los Angeles, Calif.

Before the formulas and the numerical values of the new factors, *P,* and *F,* can be used with confidence, they must be subjected to close scrutiny and to comparison, as to results, with the experiences of others. It is not, however, the present purpose of the writer to examine the derivation of these formulas, nor the calculations, in detail, but rather to attempt, by their application, to show wherein may lie their greater value; and by questioning certain statements and conclusions made in the paper, to encourage the authors, and perhaps others, to clarify and enlarge upon certain phases of the presentation.

On first study of this paper, the reaction is that the subject-matter is very involved in assumptions, and the formulas appear to be complicated to a degree that would make their use difficult by the average individual, in general practice. However, on more thorough examination, it is clear that they are not so complicated once the type of curve is selected, and that they may be used in the same manner as the ordinary empirical formula when it is desired to take advantage of the extra factors submitted by the authors.

These formulas could be made of especially practicable value if they were universally used in the reduction of field observations made to determine the proper values for *C.* A careful choosing of the type of water-shed, of correct values of *P, F,* and (hydraulic) *S,* and their application in the formulas, are not of such moment to the practitioner as is the choice of the elusive coefficient, *C.* These values are, as yet, so much a matter of judgment of the individual, based on his experience with present methods, that a change might easily leave one hopelessly undecided as to the proper choice. The introduction of the factors, *P* and *F,* results in an entire elimination of the former partly automatic correction of *C* values, and, unless the value now is chosen with extreme care, the advantages of the introduction are nullified. For instance, under the heading, "Method of Arriving at Values of Factor *P:* Remarks and Deductions" (Part II), it is stated that:

"For all practical purposes, therefore, the values of *P* (in Tables 3 and 4), shown opposite $\frac{A}{A'} = 262\,144$, and in the column headed by $P' = 0.5$, may be used when the formulas are applied without separate consideration of the inlet area, or nucleus."

These values of *P* have a range of from 0.42 to 0.62, and their significance in Equation (27), being $P^{0.5714}$, the actual values would lie between 0.61 and 0.76. If a constant value were assumed, such that $P^{0.5714}$ lay midway between these extremes, say, 0.685, the maximum error (either plus or minus), would be not more than about 11 per cent. One questions whether such refinement is warranted in everyday practice, at least until such time as the C values can be chosen more accurately. When using this same Equation (27), if one happened to pick 0.25 as a proper C value, whereas the correct one might be less or greater, say, 0.20 or 0.30, the erroneous assumption would result in a discrepancy of about 29% over design, or about 19% under design, as the case might be.

The formulas are developed logically and in a manner easily understood, except with respect to the factor, P. This appears first (see Equation (19)), as a coefficient of N, an abstract number found by inspection to be practically constant for any definite shape of channel with a given slope and Kutter's n. The next mention occurs directly under "Method of Arriving at Values of Factor P," wherein P is defined as the ratio of the average velocity of flow (through the water-shed) to the velocity at the outlet. In developing the formula, N is eventually replaced, in part, by the factor, F, representing the varying shapes and conditions of channel; and, in part, by the factor, P, as being representative of the ratio of internal velocities. It is not made very clear, however, why this factor should have this numerical value, nor why this final velocity has any bearing whatsoever.

However, if the results obtained by the application of the new formulas are found to be consistent with experience, they may well be accepted, at least in principle. The writer, for one, is not ready to concede unsoundness in all the empirical formulas, but will admit, only, that engineers sometimes use them unintelligently. These basic formulas may, then, be used as "yardsticks" and by simple comparison of the old with the new, one may consider whether or not the principle of the latter is correct, not necessarily because of the theory expounded, but because of its consistency with the former, in results.

In the following, it should be kept in mind that the C of this paper is presumed to be the ratio of actual run-off to current rainfall, whereas the C of the empirical formulas (hereinafter called C'), is merely a correcting factor, inserted for the purpose of adjusting the equation to prevailing conditions. The more important of these empirical formulas in general use,[16] re-arranged so as to be in similar general form, may be stated, as follows:

Hawksley:

$$Q = C' \, R_1^{0.750} \, A^{0.750} \, S^{0.250} \quad \text{.....(61)}$$

Adams:

$$Q = C' \, R_1^{0.833} \, A^{0.833} \, S^{0.083} \quad \text{.....(62)}$$

Burkli-Ziegler:

$$Q = C' \, R_1 \, A^{0.750} \, S^{0.250} \quad \text{.....(63)}$$

McMath:

$$Q = C' \, R_1 \, A^{0.800} \, S^{0.200} \quad \text{.....(64)}$$

Parmley:

$$Q = C' \, R_1 \, A^{0.833} \, S^{0.250} \quad \text{.....(65)}$$

---

[16] "American Sewerage Practice," by Metcalf and Eddy, First Edition, Vol. 1, p. 234.

Hering:

$$Q = C' \; R_1 \; A^{0.833} \; S^{0.270} \ldots\ldots (66)$$

Charles E. Gregory:

$$Q = C' \; R_1 \; A^{0.860} \; S^{0.186} \ldots\ldots (67)$$

and, for comparison, Equation (29) may be written:

$$Q = 15 \; (FB)^{1.1429} \; C^{1.1429} \; R_1^{1.1429} \; A^{1.1429} \; S^{0.2143} \ldots\ldots (68)$$

Equation (68) is a special reduction of Equation (24), with $i = \frac{K}{\sqrt{t}}$

Equations (61) to (68) show readily that identical results could not be obtained, from the use of any two or more of these formulas, except by a proper adjustment of the C values. There is no doubt but that each of these formulas gave results entirely satisfactory to the originator; but they proved satisfactory only because he was able to apply, intelligently, the C' values peculiar to the water-sheds upon which his observations were made and to the type of storms encountered. If these particulars were generally known, in detail, the formulas could probably be reconciled, and the mass of data, heretofore obtained, could be co-related.

An approximation can be made, which will give some idea of the relative C values, as used in the formulas of this paper, and those of one of the empirical formulas. The McMath formula (Equation (64)) is probably more widely used than any one of the others. Generally, it has been found to give fairly satisfactory results for the smaller areas, say, up to 1 000 acres, under conditions of natural flow; that is, without an improved drainage system. Assume, then, that the McMath formula and the authors' Equation (29), having $i = \frac{K}{\sqrt{t}}$, each give correct results, and equate them, as follows: Let $C' = C$, of the McMath formula, and $C = C$, of Equation (29). Then:

$$C' \; R_1 \; A^{0.800} \; S^{0.200} = 15 \; C^{1.1429} \; R_1^{1.1429} \; A^{1.1429} \; F^{1.1429} \; B^{1.1429} \; S^{0.2143} \ldots\ldots (69)$$

and,

$$C' = 15 \; C^{1.1429} \; R_1^{0.1429} \; A^{0.3429} \; F^{1.1429} \; B^{1.1429} \; S^{0.0143} \ldots\ldots (70)$$

Assume that $R_1 = 2.00$, the value originally used in the McMath formula, and that the value of S is between 10 and 100, then $R_1^{0.1429} = 1.104$; $S^{0.0143}$ lies between 1.034 and 1.068; and, taking the approximate mean of these values, $R_1^{0.1429} \; S^{0.0143}$ is called 1.160.

For natural conditions of flow, a value of $F = 4.20$ is chosen (Table 11) as being fairly representative, and $F^{1.1429} = (4.20)^{1.1429} = 5.156$. Substituting these representative values, Equation (70) now may be written:

$$C' = (15) \; (1.160) \; (5.156) \; C^{1.1429} \; A^{0.3429} \; B^{1.1429}$$

or,

$$C' = (89.71) \; C^{1.1429} \; A^{0.3429} \; B^{1.1429} \ldots\ldots (71)$$

Again, with,

$A = 10$ acres, $A^{0.3429} = 2.202$;

$A = 100$ acres, $A^{0.3429} = 4.851$;

and,

$A = 1\,000$ acres, $A^{0.3429} = 10.683$;

and, for average conditions, assume that for 10 acres, $L = 1\,325$ ft.; for 100 acres, 4 220 ft.; and for 1 000 acres, 13 250 ft. In Table 3 under "$P' = 0.5$, Medium Concentration, $\frac{L}{W} = 3$", P is found equal to 0.48. This table is used rather than Table 4, because of comparison being made with the uniform assumption. Hence, values of $B^{1.1429}$ are: 0.01081, 0.00557, and 0.00290, for 10, 100, and 1 000 acres, respectively.

Then, substituting further, Equation (71) may be written for the three assumptions of acreage, as follows:

For 10 acres:

$$C' = (1.9422\,C)^{1.1429} \qquad (72)$$

For 100 acres:

$$C' = (2.1700\,C)^{1.1429} \qquad (73)$$

For 1 000 acres:

$$C' = (2.4458\,C)^{1.1429} \qquad (74)$$

These formulas may be reduced and tabulated, for convenience of comparison, for the range of values generally used, such as is given in Table 12.

It must be remembered, however, that the comparisons in Table 12 are made on the assumption of drainage running in natural channels, or similar

channels, in each instance. In case the flow is to be in a system of conduits, to obtain the relative values of C' of the McMath formula, for natural channel flow, and C, of Equation (29), for improved channel flow, the appropriate F value (see Table 11) becomes a correcting factor. For instance, if the improved channel is to be circular pipe, with a value of Kutter's $n = 0.013$, the F value would be 6.63, and the relative values, as given in Table 12, would be corrected as follows:

(*a*).—With C' (of McMath) as a base: C (of Equation (29)) would be $\frac{4.20}{6.63} = 0.6335$ of that shown.

(*b*).—With C (of Equation (29)) as a base: C' (of McMath) would be $\left(\frac{6.63}{4.20}\right)^{1.1428} = \frac{8.688}{5.156} = 1.6850$ times the values shown.

For convenience of comparison, these values are also reduced, and tabulated in accompanying Table 13.

The values given in Tables 12 and 13, of course, are based on data presumed to apply to average conditions and for a particular type of rainfall curve. Those of Table 12 would be applicable to sub-areas with storm water running loose to the catch-basins, while those of Table 13 have reference to a drainage basin as a whole, with improved channels thoroughly covering the area. Similar tables could easily be prepared from any set of known conditions (or assumed conditions), in combination with any one of the empirical formulas. Using the McMath formula, with these tabulated values of C, the run-off, Q, was calculated for several of the illustrative problems given in the paper, and also for several drainage systems heretofore designed. This resulted, in each instance, in a value for Q approaching very closely that obtained either by the use of Equation (29), or by the detail method. Furthermore, for the particular conditions given, Tables 12 and 13 show C values fairly consistent with those usually assumed. Similar comparisons, made under extremely differing conditions, give equally satisfactory results. It may be presumed, therefore, that the formulas of this paper are of correct construction.

Throughout the paper, the presumption is that it would be incorrect to assume the individual storm as following the law of the rainfall curve; and yet, inconsistently, such storm is assumed to follow a definite law, that of uniform intensity throughout any one time interval, with the measure of that uniformity as the average for that period. True, an individual storm might not, and usually does not, follow any known law, with respect to sub-intensities; but the improbability is just as true in one case as in the other. It must be remembered that rainfall curves are, at best, probability curves based on past experience, and that the tabulated i-values are average values, for certain time intervals, which are likely to be equalled or exceeded not oftener than the stated term of years.

If the designer is unwilling to concede the individual storm as following the law of the rainfall curve, he has no authority to assume his i-values from that curve. The two are inseparable, and to use them otherwise would be as inconsistent as designing a wooden structure with working stresses based on those of steel. Admittedly, a condition of uniformity would not occur as frequently as certain equal averages, in which case, if the former is assumed, the design would not be for the expected frequency, but for a much longer term.

Any one storm may have sub-intensities which are increasing in value, are uniform, or are decreasing, throughout concentration time, and yet may have a certain average value for that interval, hence, apparently tending to produce a maximum run-off greater than, equal to, or less than, respectively, that estimated under the uniform assumption. Under such variation, however, the concentration time would change, the tendency being for this time interval to decrease, in the order in which the conditions are stated, and the consequent adjustment of i would tend, automatically, toward a stabilization of the Q value, in conformity with that produced by the storm which follows the law of the curve. This condition is recognized in the assignment of the time of concentration of the nucleus, by assuming the maximum intensity as occurring at the beginning of the storm. Also, it is recognized in the statement, attributed to C. E. Ramser, M. Am. Soc. C. E., under "Use of

Rainfall Curves," which is no doubt true and is probably universally accepted, namely:

> "The maximum rate of run-off, therefore, would result from a rainfall of maximum uniform intensity, continuing for a time equal to or exceeding the time of concentration."

One can but interpret this statement to mean what it says: The maximum will be the greatest under the uniform assumption; and, this statement being true, the tendency, with respect to the effect of sub-intensity variation, must be as stated heretofore. Much of the confusion that exists, with reference to C, is caused by the use of i-values of average intensities, from these rainfall curves, as if they were a set of uniform intensities, and by the attempts to include with C an additional factor which must vary with the type of curve. As valuable as such a set of i-values would be, no feasible method has yet been found for compiling a curve which would give duration frequencies of uniform intensities; and engineers, therefore, must get along with what they have and make the proper corrections. All rainfall curves thus far developed give these i-values of average intensities rather than uniform, notwithstanding that the late Emil Kuichling, M. Am. Soc. C. E., as long ago as 1905, called attention to the necessity for maximum rainfall data based on uniform instead of average intensities.[17]

While the routine of the detail method requires the assumption of uniformity, this is done merely for convenience and as a practicable base from which to work. Otherwise, the conception would become so involved as to render its use impossible. Recognition of the inconsistency is given, however, through the medium of the assigned values for C. In no other circumstance could one account for the comparatively small values assigned to this coefficient, nor its relatively constant value, along with changing value of intensity. If $(1 - C)$ represents only the loss by absorption, evaporation, and retention, this loss would be rather constant in volume, per unit of time, and one could not justify this volume as being a constant percentage of a variable intensity; nor could one justify the apparent large loss to current run-off. On the other hand, if $(1 - C)$ represents not only the actual losses, as stated, but also a correcting factor, for the fictitious assumption of uniform intensity, the value of C would be relatively small, and would tend toward constancy with a variable i, in such ratio as the weight of the correction.

Undoubtedly, these values of C, as used, are not the proportions of the run-off to the actually controlling sub-intensities, but are the ratios that they bear to the average intensities, arbitrarily assumed to be uniform. The fundamental relation, $Q = C\,i\,A$, is a true expression when, and only when, the factor, i, is the one actually controlling. When the values given this factor are fictitious (and it is necessary that this be done because no better data are available), a qualifying coefficient of i could well be introduced, instead of making it a part of C, and the fundamental relation might be more properly written, $Q = C\,(ci)\,A$. In such an expression, C would have its true meaning, as generally understood and corresponding with the nomenclature of this paper; and the value of c would be 1.00 when the actual rainfall is of uniform intensity for concentration time, less than 1.00, otherwise, the actual value depending on the type of rainfall curve and other prevailing conditions.

---

[17] *Transactions*, Am. Soc. C. E., Vol. LIV (1905), p. 192.

Although this factor, c, would be a coefficient of i, it is, hereinafter, so that it will not be confusing, used in conjunction with C' (as in the empirical formulas), or $C'c = C$ (as in this discussion). With c having a maximum value of 1.00, for a rainfall of uniform intensity, probably the maximum values for curves of the type, $i = \frac{K}{t^e}$, on very small sub-areas, would follow, somewhat, the logarithmic mantissa of $(1.00 - e)$. With $e = 0.4$, 0.5, and 0.6, respectively, these maximum c-values would be log (6), log (5), and log (4), or 0.778, 0.699, and 0.602. The minimum value, for the very small sub-area, would be the ratio of the end sub-intensity to the average intensity, for the respective type of curves, or 0.60, 0.50, and 0.40.

In order to allow visualization of the foreging statements, the c-values, which equal $\frac{C}{C'}$, are given in Table 14, from the values shown in Table 12, which values were determined from purely arbitrary assumptions of average conditions. Additional values are given, to clarify statements to be made presently, which were calculated simply by extending the scope of Table 12. In the McMath formula, however, when C' is given a value greater than unity, C' is no longer representative of approximately the degree of imperviousness, but is increased for other reasons. Therefore, in Table 14, for this higher range of C'-values, c would equal $\frac{C}{1.00}$ instead of $\frac{C}{C'}$.

A review of the method of making Table 12 and Table 14, would show, the other factors remaining constant, and for a rainfall curve of type, $i = \frac{K}{\sqrt{t}}$, that:

1.—With a change of C' (of McMath):

(a) C (of Equation (29)) varies as $\sqrt[1.1429]{C'}$.

(b) Within the range of $C' = 0$ to 1.00, c varies as $\frac{\sqrt[1.1429]{C'}}{C'}$.

(c) With C' larger than 1.00, c varies as $\frac{\sqrt[1.1429]{C'}}{1.00}$.

2.—With change of area size:

(d) $c^{1.1429}$ and $C^{1.1429}$ (of Equation (29)) vary inversely as $(B^{1.1429}\ A^{0.3429})$.

3.—With change of intensity:

(e) $c^{1.1429}$ and $C^{1.1429}$ (of Equation (29)) vary inversely as $R_1^{0.1429}$.

4.—With change of slope:

(f) $c^{1.1429}$ and $C^{1.1429}$ (of Equation (29)) vary inversely as $S^{0.0143}$.

Assuming that all sub-areas, subsequent to the nucleus, have a concentration time either equal to, or less than, that of their respective contributing inlets (which must be, under the conceptions of the detail method), the controlling i-factor will be that occurring subsequent to the time of fall of that "remote drop" which is destined to join the "remote drop" from the nucleus; that is, if the t of the inlet is 60 min. and that of a certain sub-area is 20 min., the measure of the run-off from that area, in the maximum concentration from the whole, will be the actual intensities occurring during the interval (60–20) to 60 min.; and could not be the intensities prevailing during the interval, 0 to 60 min. If, subsequent to the (60–20) moment, just cited, the actually controlling intensities are less than those of the (0 to 60)-min. period (and the form of the generally accepted rainfall curve would warrant such an assumption), the maximum simultaneous run-off concentration, from this sub-area, could only be measured by the lesser rate of fall.

The concentration time at an inlet point being the timing of the "remote drop" from the nucleus, it can be seen that the corresponding factor, c, would be representative of the period from zero minutes to the end of the concentration time, and, therefore, would be at its maximum value. If a sub-area, contributing at a certain inlet, had a concentration time equal to that of the

inlet, the value of c, applying to the sub-area, would be this same maximum; but if the concentration time of the area were extremely short, the factor, c, would have a minimum value. The effect of each sub-area, on maximum simultaneous run-off from the whole, therefore, would be at its greatest when its concentration time equalled that of its tributary inlet; and at its minimum, when its t-value is only a small fraction of that of the inlet.

The relation between these two concentration times, therefore, becomes an important factor in the measure of maximum concentration. The shorter the t of the sub-area, the more frequent will be the turn-over of representative rainfall, and the controlling i factor will be that of the average intensity for the last frequency period of flow in which the "remote drop" from the area joins the "remote drop" from the nucleus. If t represents the concentration time of the sub-area, and T that of the inlet, the ratio, $\frac{T}{t}$, might be called the "turn-over frequency" of the area, and, in general terms, it may be stated, that the larger the turn-over frequency of any sub-area, the less effect that area will have in the measure of final simultaneous run-off, the C value, consequently, being smaller with such increase.

Conceding this conception, one could visualize, as one extreme, a small impervious sub-area, with $t = 1$ sec., and T at its tributary inlet quite large. In such a case, the controlling i factor would be the current rate of fall, which with a curve of type, $i = \frac{K}{\sqrt{t}}$, would be one-half the average applying to the T of the inlet, or $c = 0.50$, and $C'c = (1.00)\ (0.50) = 0.50 = C$. As the other extreme, if $\frac{T}{t} = 1.00$, the controlling i factor of the area would be the same as that of the inlet, or $c = 0.70$, and $C'c = (1.00)\ (0.70) = 0.70 = C$. The range of C values, on small impervious areas, therefore, lies between 0.50 and 0.70, corresponding to the extremes of the turn-over frequency being infinitely large and of its being unity, respectively. On the other hand, in the case of a similar small sub-area, partly pervious, these limiting values of C would be different. The area of practically instantaneous run-off could have very little, if any, loss by absorption, evaporation, or retention, thus holding the C' value approximately at 1.00 (notwithstanding the area may be mostly pervious), and $C'c$ would be 0.50, as before. If $\frac{T}{t} = 1.00$, the area would sustain such losses, C' would be less than 1.00, and $C'c$ less than 0.70 (as estimated for wholly impervious areas). If the correct C' value were 0.10, and the corresponding c value slightly less than 0.70, say, 0.69, then $C'c = C = (0.10)\ (0.69) = 0.069$.

The range of C values, on small pervious areas, therefore, lies between 0.069 (or less), and 0.50, corresponding to the extremes of turn-over frequency being unity and of its being infinitely large, respectively. As the C' value increases from zero to 1.00, the corresponding c factor decreases from 0.70 to 0.50, and the product, $C'c$ (or C), would reach its maximum when $C' = 1.00$. From the foregoing, it may be noted, also, that C' (of the McMath formula) is not a measure of imperviousness of an area, but rather a coefficient expressing the effect of the combination of the degree of imperviousness and the ratio, $\frac{T}{t}$ It has a value of 1.00 when $\frac{T}{t}$ is infinitely large; decreases to zero as $\frac{T}{t}$ reaches unity and the degree of imperviousness reaches zero; and increases to its maximum value when the area is wholly impervious and the ratio, $\frac{T}{t}$, is unity.

These statements are made, specifically, with respect to the sub-area effect on the area as a whole, with concentration times of the sub-areas, and of the inlet points, being shown as controlling factors. Exactly the same conditions would apply to the sub-areas, considered independently, the minor subdivisions of these areas being substituted, and inlet points being considered as collecting points for flow from the sub-divisions. The controlling factors, in such a case, are not so easily ascertained, because of the infinite possible variation of such minor concentrations. Resort must be had to judgment based on experience, and on the foregoing conceptions, for the correct assignment of these C values to the sub-areas. If the experiments of McMath are correctly reflected in his formula, and the average conditions he encountered were approximately those herein assumed, the C values of Table 12 would be approximately correct.

However, no pretense is made that the data in Tables 12, 13, and 14 are numerically correct, because the writer does not know the exact conditions under which the McMath observations were made. They do show, nevertheless, a remarkable consistency of trend, and of limiting values, with the foregoing analyses, and demonstrate conclusively that, not only do the detail method and the empirical formula assume the individual storm as following the law of the curve, but that this is true also of the formulas presented by the authors.

Many deductions, comparisons, and analyses of differing features could be made from the foregoing. In general, however, it may be stated that, with a rainfall curve of the type, $i = \frac{K}{\sqrt{t}}$, any area characteristic which increases the turn-over frequency of its sub-areas will decrease the value of C and *vice versa.* An increase in sub-area size (T larger), of intensity (t smaller), and of slope (t smaller), will increase the value of the ratio, $\frac{T}{t}$, in consequence of which C values will decrease. The increase in degree of imperviousness (which decreases t), would also cause a change in the same direction, except that the trend is reversed by the decreasing ratio of actual loss, by evaporation, absorption, and retention. The actual variation of C values, caused by change in the foregong relations, is entirely dependent upon the type of curve. A few simple comparisons, made with other values for e, show clearly the reason for the differences among the various empirical formulas.

When the sub-areas are considered as part of the whole, their respective C values will remain constant only when the turn-over frequency of the area, or $\frac{T}{t}$, is unity. Otherwise, C must depart from these independently determined values, and will be more, or less, according to circumstance. As each sub-area is encountered along the course of the main channel—an increase in time—the ratio, $\frac{T}{t}$, would increase, of course, although t would increase slightly because of decreasing intensity. The latter may be disregarded, however, for any change to be made in the C value, because of the changing ratio, $\frac{T}{t}$, would be based from the original values of both C and t.

Theoretically, then, with increase in time, C would be reduced in such measure as the $\frac{T}{t}$ value departed from unity. Practically, however, this trend might be nullified, or even be reversed, if increasing wetness of the area increases the real value of C'. Especially in the lower bracket of values, if the original assignment of the C' value is based solely upon the percentage of impervious surface, without regard to what the condition of the pervious parts would be when thoroughly wet, the theoretical trend would most certainly be reversed; and C would have to be increased with increase of time. The underlying reasoning back of the original assignment, with respect to perviousness, wetness, size, and relative position of the sub-area, would determine whether C should, later, be increased, remain constant, or be decreased. Probably each of the authorities, who do one or the other, are correct, basicly, founding their action on the characteristics of the watersheds to which the applications are made, on the type of rainfall curve appertaining to his locality, and on his original assignment of the C' value.

The initial sub-area, or nucleus, becomes of importance in the detail method, not, primarily, because of its physical characteristics, but because of the interval chosen as its concentration time. This value of t is added to the calculated time in the drains, in order to arrive at concentration times of subsequent inlets, which, in turn, determine the respective intensities. Thus, the assumed t of the nucleus becomes a factor in the whole design, of greater weight if total time is short and of less consequence if it is large. With a curve of the type, $i = \frac{K}{\sqrt{t}}$, if 10 min. is chosen as initial inlet time, whereas 15 min. would be correct, the corresponding intensity values would be in error about 22%; and at the end of the total time of 1 hour, this error would be reduced to 5%; but this error would be nullified, except as to the nucleus, if due consideration is given to the C value change on subsequent areas. The ratio, $\frac{T}{t}$, for the latter, would be different with the erroneous assumption, and C values on these subsequent areas would change accordingly, the tendency being to offset the seeming error. Nevertheless, initial inlet time should be chosen as accurately as possible.

In their discussion in Part I, the authors observe and comment on many seeming inconsistencies in the empirical formulas, and in the assumptions of the detail method. Obviously, it would be inadvisable to comment on each of these, separately, because of the space required. Many of their queries are reconciled in the foregoing analyses, and many of the apparent inconsistencies turn out to be entirely logical. Some of the more important of these may be recalled, briefly:

In their "Introduction" the authors state that, "one purpose of this paper, however, is to show why the use of these empirical formulas is not now to be recommended," whereas, actually, their own theory may be established by the use of them.

The conclusions drawn from the illustration of the simple water-shed (see Table 1) are based upon the impossible assumption of unity for the C values, and that these values would remain constant under the stipulated conditions. The several columns of tabulated values of Q (Table 2), would hold only when the average intensities, shown for each sub-area, are considered as being uniform, and as continuing at their respective rates for the entire concentration time of the total area.

Preceding the authors' conclusions to Part I, the statement that "to increase Factor C as the time increases (as shown in current publications and textbooks), without also allowing for the fluctuation in C for changing intensities, seems entirely unjustified," cannot, itself, be justified. It has been shown, earlier herein, by using Equation (29), that the weight of i, in so far as it affects the factor, C, is $R_1^{0.1429}$, and that C varies inversely as this value.

It has been previously shown that, with N a constant for any set of conditions, $C' = NC^x$, and C, therefore, varies as $(C')^{\frac{1}{x}}$; also, since $C = C'c$, c varies as $\frac{(C')^{\frac{1}{x}}}{C'}$.

With $\frac{T}{t} = 1.00$, the ratio of actual intensity to average intensity is 1.00; and, with $\frac{T}{t}$ infinitely large, the ratio of actual intensity to average intensity is $(1.00 - e)$. The mean of these two extremes is $(1.00 - \frac{e}{2})$, and the equation of the curve for values of C and c is, therefore, the log of this mean, and $\frac{1}{x} = \log\,(1.00 - \frac{e}{2})$, and $x = \frac{1}{\log\left(1.00 - \frac{e}{2}\right)}$.

With respect to the effect of intensity on C values, the authors show that velocity varies as $Q^{\frac{1}{4}}$; hence, t^e varies as $\frac{1}{R_1^{\frac{e}{4}}}$, and the ratio, $\frac{T^e}{t^e}$, varies as $\frac{T R_1^{\frac{e}{4}}}{1}$. The equation for the curve, for the effect on C' values, is, therefore,

$$\frac{ex}{4} = \frac{e}{4\left(\log\left(1.00 - \frac{e}{2}\right)\right)} \quad \text{......................} (75)$$

With a rainfall curve of the type, $i = \frac{K}{\sqrt{t}}$, the exponent for the curve of C values, or x, is, $\frac{1}{\log\left(1.00 - \frac{0.5}{2}\right)} = \frac{1}{\log 0.75} = \frac{1}{0.8750613}$; and $x = 1.14277$. The effect of intensity, on C' values, is $\frac{ex}{4} = \frac{0.5x}{4} = 0.1429$.

In a similar manner, it can be shown that the effect of the slope on C' values would be, $\left(\frac{e - e^2}{2}\right)\frac{x}{10} = 0.0143$.

These are the exponents obtained by equating the McMath formula with Equation (29) to obtain Equation (70).

The authors are most vague as to their reason for inserting the factor, P, in Equation (19), but a study of its significance in the final expression (Equation (24)) would indicate this factor to be merely a measure of the effect of the ratio, $\frac{t}{T}$, on maximum run-off. In other words, the factor, P, is a measure of the reduction of C values (as assigned to the sub-areas, independently) required by the average value of the ratio, $\frac{t}{T}$. The latter, of course, would be different for each type of water-shed (see Fig. 2) and for each type of rainfall curve; but, also, these P-values (see Table 4) would change, for any one type of water-shed, or rainfall curve, if the slope of the area were variable, or if it differed considerably from that of the main channel, and if the C-values were different on the various parts, Table 4 being calculated with the assumption of uniform slope and a constant C-value. The suggestion is made that one table might answer the purpose better, wherefrom, with average $\frac{t}{T}$ -values for guides, P-values could be selected appertaining to the more generally used types of rainfall curves.

Table 3 is mis-named, in that the value of P has no significance when the storm is of uniform intensity. Under such condition, the value of e is zero, and any value of P, with zero for its exponent, has no meaning.

The illustration of the tabling process (Table 8) is useful for demonstrating the consistency of the suggested formula, but it might be very misleading with respect to the assigned values of C. Although the slopes are fairly uniform, this factor is assumed to be the same for the extreme variation of areas of 1.5 and 108.6 acres, respectively. It might be possible, but not very probable, that these sub-areas, individually, have equal C-values, but each, as a part of the whole, could not possibly have such equality.

In conclusion, it may be said that the paper presents many valuable and original suggestions and that the authors are to be commended for their really fine effort. Two additional factors are introduced which are of vital importance, and their adoption can only lead to a more precise determination of real C-values. A word of caution must be uttered, however, against the general use of these formulas without a thorough understanding of the effect, and importance, of the C-value assignment. The introduction of these two new factors carries with it the necessity for a very much greater refinement in these selections, which, if not done with proper knowledge, may easily lead to results more erroneous than if they had not received consideration.

John W. Raymond, Jr.,[18] **Esq.** (by letter).—This paper discusses the problem of designing culverts, bridge openings, storm drains, spillway structures, etc., in which it is required to estimate maximum flow. The estimation of discharging capacity for bridge openings, culverts, spillway structures, and flood channels, while involving basic data very similar to those required for determining flows to be provided for in storm drains, is nevertheless a distinct problem. Since it is usually considered good engineering to provide for the maximum flow to be expected in the first case, in storm drain and combined sewer design, it is rarely practicable, financially, to provide conduits throughout a drainage area, to care for the maximum flows. Thus, the problem of storm drain or combined sewer design introduces the estimation of frequency and of balancing of damages and inconvenience resulting from occasional flooding, against the extra cost of providing conduits for the larger expected flows.

While both problems deal with structures which are continually in use, the problem of designing storm drains and combined sewers is to provide a system within the funds available and in agreement with the degree of protection required, and the rate of flow to be provided for is that expected at occasional intervals, say, on the average of once in 5, 10, or 15 years. The problem of estimating discharge capacity for culverts, bridge openings, spillway structures, etc., requires the determination of the maximum flow to be expected in more than 100 years, or perhaps even 1 000 years. Thus, the conditions for the design of the latter structures require the determination of the maximum rainfall conditions, together with the maximum run-off conditions, and the problem of storm drain and combined sewer design requires the determination of the rainfall to be expected at a given frequency and average run-off conditions, since the condition of simultaneous maximum or excessive rainfall and maximum run-off is of rare occurrence.

Considerable labor is involved in the tabling process as practiced by a number of engineers. For a system of storm drains or combined sewers to be designed by means of the Gregory and Arnold formulas, probably the most convenient way to arrange the computations would be in tabular form for the different sections of the conduit, substantially as is done in the tabling process for the rational method; and it seems to the writer that the number of columns and the labor involved would not be far different in either case.

---

[18] Asst. Engr., Metcalf & Eddy, Boston, Mass.

It is not axiomatic that the maximum flow resulting from a rain of given frequency occurs when the entire area is contributing; it is generally true, especially for areas which increase substantially as the time of flow. It may not be true where a water-shed consists of large individual areas, the main channels of which have different slopes from that of the main channel for the whole water-shed or where the development or proportion of impervious surface of the individual areas is widely different. Engineers using the tabling process in the rational method of design should investigate their design for durations shorter than the time required for the entire area to contribute, to find the maximum flow resulting from the selected frequency rainfall curve.

It is true that intense rains seldom occur at uniform rates for long durations. It is believed, however, that with a complete system of storm drains or combined sewers, consisting of closed conduits, the use of uniform intensities of rainfall gives substantially correct results, on account of the limited capacity of the conduits. This causes water precipitated during the short periods of excessive rainfall to be retarded, thus smoothing out the run-off. If the rainfall curve is constructed from records of all storms, it may be used with reliability in determining the frequency, provided the records cover a sufficient number of years.

Where the proportion of impervious surface is uniform, the run-off factor, C, for a storm beginning at a time when run-off conditions on the area are average, or when the area is not completely saturated, is known to increase with time, and when this is taken into account the different values of Ci vary less than the i values.

The detailed method as practiced by most engineers is not based on the assumption of the equivalent of a variable intensity during the period of concentration, but upon the assumption of a uniform intensity for each period, or in other words, the storm used for each part of the drain is a different storm than those used for the other parts.

The usual method of construction or derivation of rainfall curves includes all significant storms, and in a record the length of which is several times the period of frequency represented by the design curve, there will be several storms which will define the position of the frequency curve. It is incorrect, therefore, to assume that the run-off at a given point resulting from a storm of a certain frequency, is made up from rainfalls of diminishing intensities, different intensities being applied to different parts of the drainage area, since the ordinate, i, equals the total fall divided by the duration.

The authors have presented a valuable discussion of the problem of estimating storm flows. It is difficult, however, for an engineer experienced in the use of the so-called "detail rational method" to visualize the bearing on the problem of the different coefficients and constants which are suggested. If the formulas were felt to be applicable, a great deal of experience in their use would be required, to obtain reliable results. On the other hand, where the detailed rational method is used for storm drain design, an experienced engineer may select the basic data, that is, the frequency rainfall curve, degree of development, and coefficients of run-off; and he may then explain the method of computation to a less experienced assistant, who can complete the labor of design, and reliable conclusions can be reached. It does not appear to the writer that the labor involved in working out the results of the suggested formulas can be entrusted to an inexperienced assistant to the same degree.

The authors have clearly pointed out the inadequacy of empirical formulas, and their continued future use for estimating the required capacity for important drainage channels and waterways can scarcely be tolerated.

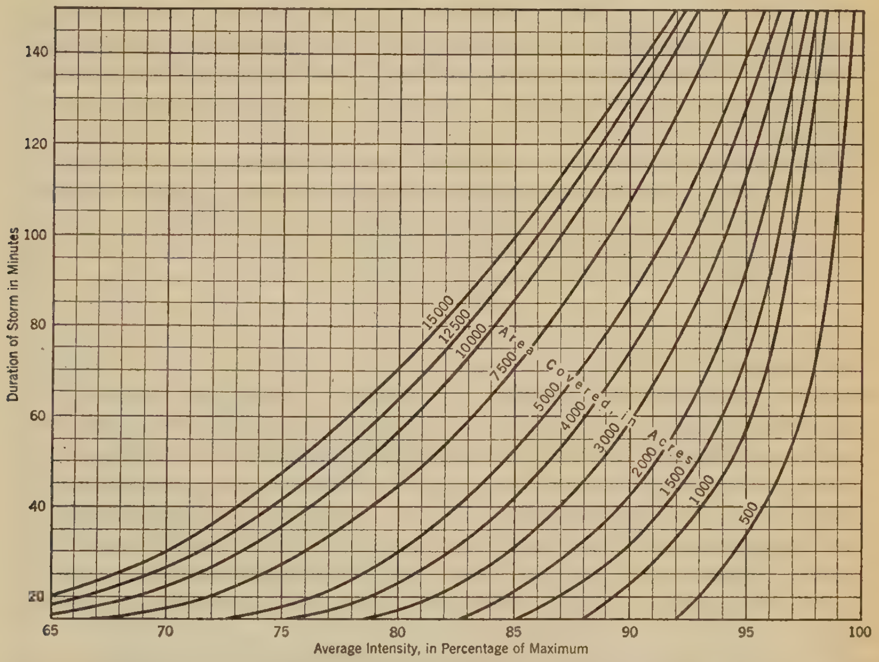

FIG. 8,—DISTRIBUTION OF RAINFALL INTENSITY WITH RESPECT TO AREA COVERED AND DURATION OF STORM FOR 15-YEAR FREQUENCY STORMS AT LOUISVILLE, KY.

Probably the "inlet time" as used in the rational method of storm drain design gives engineers the most concern because of the paucity of reliable data, and the need for more observations cannot be over-emphasized.

The distribution of intense rainfall over the area of a water-shed is an important factor. Excellent data for rainfalls of short duration have been presented[19] by Frank A. Marston, M. Am. Soc. C. E. Fig. 8, which is from the report of the Commissioners of Sewerage of Louisville, Ky., dated October 16, 1929 (and prepared from data in Mr. Marston's paper, and some subsequent data), shows the relation between the average and maximum intensities for different areas and durations.

[19] *Transactions*, Am. Soc. C. E., Vol. LXXXVII (1924), p. 535.

Reginald A. Ryves,[20] Esq. (by letter).—This paper represents a formidable mathematical effort which prompts the question, "Why seek a formula when all data and assumptions can be applied directly by a graphical statement?"

The first necessity in making calculations of the flood discharges of catchments is to have some means of comparing any catchment with any other catchment, even when they differ much in size. Comparisons by means of rates of flow per square mile are of little use, since an accompanying scale of the effect of size has to be used in order that the comparison may produce a relation which represents rainfall and run-off conditions only. On the other hand, formulas involving a consideration of the shape of the area are not satisfactory, because, in comparing two catchments, more than one variable is involved, so that a relation which represents the rainfall and run-off conditions only is not arrived at, although the formula involving shape may give a more accurate result in the estimate of the run-off of a particular catchment.

If shape is to be considered, orientation is, in some cases, of great significance.

The only satisfactory way of making general comparisons is the use of a simple formula, such as that of Colonel Dickens, first applied in Bengal:

$$Q = C_1 M^{\frac{3}{4}} \qquad \text{(76)}$$

or that of Maj. J. G. Ryves, first applied in Madras:

$$Q = C_1 M^{\frac{2}{3}} \qquad \text{(77)}$$

In Equations (76) and (77) C_1 ranges normally from 450 for flat districts near the coast to 700 for limited areas near the hills. However, in the great floods that occur about twice in a century, C_1 will equal 1 000 in many areas. Both equations have been in frequent use in India for more than fifty years, and the choice of one or the other definitely depends on topography, the former in relatively infrequent conditions, while the latter is of almost world-wide applicability. By Equation (77) the flood run-offs of a large number of catchments in the arid and semi-arid areas of the United States, as well as those of catchments in India and other countries, have been made available as bases of comparison, and as checks on the general correctness of detailed calculations. The coefficient is the criterion.

The likely coefficient for a given catchment is found by considering the coefficients in a number of cases in which the area is not very small or very large in comparison, and where the intensity of a short-period rainfall is about the same.

More significant data are provided when: (*a*) The topography is somewhat similar; (*b*) the area is not more than three times nor less than one-third the area under consideration; and (*c*) the intensity of rainfall for the significant period is about the same. The significant period is the period of total contribution, or the time it takes for water to flow from the part of the catchment most distant, in time, to the outlet. In some cases, however, a smaller area, eliminating salients, gives a larger run-off because of the greater rainfall intensity.

---

[20] Cons. Engr., London, England.

Such comparisons are very useful and important; but for final estimates of floods the writer always uses the most careful methods of direct calculation, by methods of his own,[21] which are quite probably also followed independently by other engineers, and may be held to represent the rational method as criticized by the authors. The procedure is as follows, the specific references being to the writer's computations made for the "Obras Contra as Seccas" Department of the Government of Brazil, in 1920-1922:

1.—Rainfall maps, made in exactly the same manner as those of annual rainfalls, are prepared, except that one is made for each day, for the appropriate period; that is, a period long enough to overlap the "period of total contribution" by about 50% before, and 50% after.

2.—The area is divided into a suitable number of portions, usually four or five in the cases under consideration, and these portions are either each a catchment in itself, approximately, or they are zones, the bounding lines of which will divide the streams which have a 4 hours' run to the outlet, from those which have an 8 hours' run to the outlet, etc. There will be greater differences for larger catchments. The choice between these two methods of forming elements of area is decided by the shape of the catchment and the direction in which the streams run.

3.—From the part of the rainfall map, of each day, for each element of the area the daily rainfall is calculated, zone by zone, and the average found, for the purpose of a general check.

4.—From curves of daily run-off, the run-off for each element of area is calculated.

5.—The velocities of different lengths of the main stream and its affluents are estimated, from any available data, or by judgment, and the period of delay is deduced for each element of area, or zone. This is the period that must elapse before the water flowing from the element will reach the outlet. It is measured from the center of the area, or, if all the areas are of about the same size, and are roughly each a catchment, it may be measured from the outlet of the area. In the latter case the "gathering time" for an element is computed, and this is a "general handicap" for all the run-off curves as plotted to the time base line.

6.—On a base line, marked off in hours to an open scale, the daily run-offs are plotted, first as horizontal lines, and then as continuous curves, bounding the same area as the horizontal line, each day; but all these curves do not start at the same point. Each is given a handicap, to the left of zero time, this handicap being, in each case, the period of delay. The longest handicap, plus the "gathering time" of that element, is the "period of total contribution."

7.—By totaling the heights of the run-off curves which are in cubic feet per second, at every hour-point for very small catchments or at longer intervals for larger catchments, the curve of total run-off is obtained.

The maximum run-off and the time of the maximum run-off are obtained from Steps 1 to 7 directly. The engineer is now able to judge, from the position of the time of maximum run-off on the base line, whether he is likely to get a greater run-off by taking a shorter period with a greater intensity of rainfall; or by taking a longer period with a less intensity of rainfall. Usually, however, all that he needs to do is to take a period that includes the day of greatest recorded rainfall, which in the case of the larger catchments, may involve the preparation of more than one map, since different stations may not have recorded their maxima in the same storm.

---

[21] *Indian Engineering*, April 29, March 6, and May 11, 1911.

As the rainfall stations in Northeast Brazil are not very close together, the writer assumed that the real maximum spot rainfall is heavier than that recorded at any station, which is a matter of importance in estimates of floods from the smaller catchments

As regards estimating the velocities of the streams, this might seem to be a weak link in the chain of reasoning, but the records of the Department, which include curves of rainfall and run-off plotted together, make it possible to find, in a number of cases, not only the time elapsing between any great intensity of rainfall and the corresponding intensity of run-off, but also the period elapsing between the beginning of a heavy rainfall on the dry catchment, and the moment when the stream at the outlet begins to flow.

When the "period of total contribution" has been found, or estimated, preliminary estimates of the maximum flood from any catchment may be made by averaging the "weighted" daily rainfalls of the stations in and around the catchment for a somewhat longer period, and from the curve thus obtained selecting the greatest average fall for any included period equal to the period of total contribution. The run-off appropriate to this fall is, at first sight, the maximum. A shorter period, however, may give as large, or a larger, run-off, although the entire area has not contributed; thus, consider an area, A, with three days as the period of total contribution. The precipitation for three successive days was 2.4, 7.9, and 2.2 in., respectively, or an average precipitation of 4.2 in. (0.35 ft.) per day. For such a rainfall a run-off coefficient of $\frac{5}{7}$ was suitable, under the conditions, giving $\frac{5}{7} \times 0.35 \times A = 0.25\,A$ cu. ft. per day, for the short period of the peak of the flood.

On the other hand, one day's rain in the part of the area nearest the outlet, where the stream velocities are greatest, will be gathered in many cases, from more than one-third (say, five-twelfths) the area. For the intense rainfall of 7.9 in. (0.658 ft.) per day, the coefficient of run-off is taken as $\frac{9}{10}$, and the run-off is, $\frac{9}{10} \times 0.658 \times \frac{5}{12} A = 0.247$ cu. ft. per day, at the peak. It is obvious that, since a period of one day gives nearly the same result as a period of three days, in this preliminary estimation, a complete diagram for the whole period is necessary.

If there are small outlying portions on the far side of the catchment, the actual result would be that the calculation for one day would give the greater flood. These special tests are often worth while. In the present connection their main significance lies in their obvious superiority to any formula and their equally obvious inferiority to the hour-by-hour graphical computation.

In some cases of direct calculation from the period of total contribution, the maximum flood is that found by calculating for an area which is the catchment less any extreme outlying portions. In the case of a long and narrow catchment it may be necessary to treat the whole of it, step by step, in the same way, because the maximum flood may be that due to a short period of heavy rainfall on quite a small proportion of the catchment, next to the outlet. The writer has found that this is especially possible in Northeastern Brazil, where the heaviest rainfalls in any day are often those due to intense falls of much less than a day compared with the average for one day.

It is clear that a formula is of small value compared with calculations based on the period of total contribution, and it is even more certain that, for final estimates, no other system of computation is in the same class with direct calculations carried out as described herein.

The accuracy of the computations depends upon the different periods of "delay" being adequately represented. Therefore, there must be division into areas, the centroids of which are at various distances from the outlet. Usually, a good method is to define, approximately, nearly whole catchments for the more distant parts of the area and part catchments for the sections nearer the outlet. The latter should be separated laterally by known or assumed water partings and, on the other two sides, by lines corresponding to those dividing the zones. In zoning, the lines are irregular, so as to give approximately the same "delay" for the entire zone. Division of the catchment into radial sectors fails to utilize the most important feature of division into elements, and is only a little more accurate than a crude whole-area computation, yet such a crude computation is more accurate than any formula, since it allows of the use of smooth curves of rainfall intensity and changing values of the run-off ratio.

The authors have made a very useful contribution to the study of the subject, but, in the writer's opinion, they have failed either to disestablish the rational method or to establish new formulas. First, however, it should be noted that their opinion that the use of empirical formulas is not now to be recommended, is unacceptable—as so expressed without qualification—to those who, like the writer, have found them, in their simplest forms, to furnish very useful comparative data, not otherwise available.

As regards the description of the detail method, this is fundamentally that of the writer, who, for preliminary calculations, or in the absence of rainfall data sufficient to draw the isoplanes for successive days, or shorter periods, uses a rainfall intensity curve. That shown in Fig. 1 is a good characteristic curve very similar to those drawn from data of storms in England, India, and Brazil. It is not, however, a fair presentment of the (detail) rational method, which the writer is defending, because rain-gauge data are used (or should be used) whenever available. Again, in Table 1, the bands, a_1, a_2 ... a_n, correspond to zones, but irregular lines based on estimates of rates of flow must give more accurate results than parallel straight lines. Such irregular lines, therefore, are drawn (or should be drawn), when the area does not lend itself to division into elements which approximate to separate catchments. The "Statement" preceding Table 3 certainly does not apply to the writer's method, by which, as nearly as possible, the rainfall of every small element and the run-off corresponding to it are given hour by hour.

There is, however, a broader and more significant consideration, which the authors have overlooked, namely, that the method really gives the nearest estimation of maximum run-off, whether it is due to the rainfall of the whole period of contribution over the entire catchment, to that of a somewhat shorter period (salients being excluded), or to that of a fraction of the period, such as one-third.

A reversion to the use of formulas, as advocated by the authors, would give, therefore, less reliable estimations, because no formula relates, as does the diagram—hour by hour in time and element by element in area—the factors of "pre-soakage," run-off in proportion to rainfall, rates of flow, and the least inaccurate representation possible (by a smooth curve) of the rainfalls of days and those of shorter periods for which it may have been measured. In any case, engineers are not likely to use to any considerable extent a method involving calculations the character of which is indicated by Appendix I.

G. S. Tapley,[22] Assoc. M. Am. Soc. C. E. (by letter).—The authors have made perhaps the most thorough analysis of the problem of run-off which has appeared to date. They have pointed out a slight fallacy in the present detail method. They have defined several factors (notably slope) which have not heretofore been clearly understood, and, with good logic, have discussed other factors. Only superficial criticism can be offered.

Probably the least easily understood feature of the analysis relates to P, the factor which introduces into the equation the effect of shape of area and manner of concentration. Apparently, P is a dimensionless factor obtained by trial solutions of sample cases. The writer would like to see a demonstration proving that two areas for which P is equal are geometrically similar as to shape of area and arrangement of the system, because this is implied.

A little confusion in notation exists where the factor, P, is introduced forming Equation (19). Possibly the authors had in mind the desirability of keeping the number of symbols at a minimum. In Equation (14), $c\sqrt{r}$ represents average conditions, whereas the symbol, Q, in the same equation represents the final value. In Equation (18) if Q still represents the final value then $c\sqrt{r}$ must also represent conditions at the final stage, since $c\sqrt{r}$ and Q are coincident factors at a given point. In Equation (19), $c\sqrt{r}$ represents average values, although Q is the final value. In this equation, P has been introduced to convert the final value of $c\sqrt{r}$ (corresponding to the final Q) to the average value.

Although the idea involved in introducing P is simple, it may not at once be obvious. Adopt the notation c', r', Q', v', and s' for elements at any point in the system; c, r, Q, and V for elements at the lower end; and c_a and r_a for average values. Then, at any point,

---

[22] With City Engr.'s Office, Los Angeles, Calif.

$$(c' \sqrt{r'})^{0.5} = N \, (Q')^{\frac{1}{8}} \qquad \text{(78)}$$

Also, $c' \sqrt{r'} \propto v'$; hence, $\dfrac{c' \sqrt{r'}}{c \sqrt{r}} = \dfrac{v'}{V}$, and,

$$c' \sqrt{r'} = \frac{v'}{V} c \sqrt{r} \qquad \text{(79)}$$

Therefore, at the average point,

$$c_a \sqrt{r_a} = \frac{v}{V} c \sqrt{r} = P \; c \sqrt{r} \qquad \text{(80)}$$

but, at the final point, it follows, from Equation (78) that,

$$(c_a \sqrt{r_a})^e = P^e \, N^{2e} \, Q^{0.25e} \qquad \text{(81)}$$

which corresponds to the authors' Equation (19).

In defining average slope as a function of time the authors have cleared up a point which has been puzzling storm drain designers. It has been the custom to consider the slope of an area as being determined by certain geometrical dimensions of it, but, since the authors have pointed it out, it is realized that an essential element of slope is time.

It is believed that the derivation of Equation (36) would be more lucid if a mathematical notation were used. As the authors have stated, $t \propto \dfrac{1}{F^2 \, S^{\frac{3}{8}} \, Q^{\frac{1}{4}}}$, in which the factors represent conditions at any point, S being the independent variable. That is,

$$t = u \, \frac{1}{F^2 \, S^{\frac{3}{8}} \, Q^{\frac{1}{4}}} \qquad \text{(82)}$$

Consider any particular interval, $\Delta \, t_n$, of time:

$$\Delta \, t_n = u \, \frac{L_n}{F^2_n \, S^{\frac{3}{8}}_n \, Q^{\frac{1}{4}}_n} \qquad \text{(83)}$$

The total time is,

$$T = u \sum \frac{L_n}{F^2_n \; S^{\frac{3}{8}}_n \; Q^{\frac{1}{4}}_n} = u \, \frac{1}{S^{\frac{3}{8}}_a} \sum \frac{L_n}{F^2_n \; Q^{\frac{1}{4}}_n} \qquad \text{(84)}$$

in which, S_a is the average slope. Hence,

$$\frac{1}{S^{\frac{3}{8}}_a} = \frac{\displaystyle\sum \frac{L_n}{F^2_n \, S^{\frac{3}{8}}_n \; Q^{\frac{1}{4}}_n}}{\displaystyle\sum \frac{L_n}{F^2_n \; Q^{\frac{1}{4}}_n}}$$

from which Equation (36) follows.

In deriving Equation (39) it is believed that a different definition of m is required in order to permit a logical following through of the development. If, for example, m is defined as the percentage of $(i - z)$ stored, a consecutive development results. Since $(i - z)$ equals the number of cubic feet per second per acre (storage plus run-off), $m \, (i - z)$ equals cubic feet per second per

acre, storage. Hence, $(i - z) - m\ (i - z)$ equals cubic feet per second per acre, run-off; or, $A\ [(i - z) - m\ (i - z)]$ equals cubic feet per second, run-off. Since, however, CiA equals cubic feet per second, run-off,

$$CiA = A\ [(i - z) - m\ (i - z)]$$

or,

$$C = \frac{(i - z) - m\ (i - z)}{i}$$

from which Equation (39) follows.

In the paragraphs following Fig. 1, and at several other points, the authors state, "* * * it is the evident intention [of users of the detail rational method] to assume a uniform intensity over the entire area throughout the time of concentration * * *." The idea involved, however, is somewhat obscure.

At any point in the system the discharge is computed from $Q = CiA = Ci\ a_1 + a_2 + \ldots a_n$; that is, each element Σ of area is multiplied by the same value of i. Hence, since the various elements of area, $a_1\ a_2$, etc., did not receive their contributions of rainfall at simultaneous times, i must not have varied with time, and, therefore, must have been constant.

The use of uniform intensities entails the assumption that the conduit in the upper part of the system will not be flowing full. Hence, as the authors have now made apparent, the use of the detail method involves fictitious velocities.

The authors' formulas have obvious applicability as improvements over existing empirical formulas for computing flow at a point. For designing a system, however, the proposed method is not a short cut, since, of course, the conduit would have to be designed in detail from inlet point to inlet point.

W. I. HICKS,[23] ESQ. (by letter).—This paper is an exhaustive, logical, and thorough résumé and analysis of fundamental and mathematical data on the subject. It throws new light on various hitherto obscure and neglected basic principles and tends to close up several mistaken channels of thought which have been established by erroneous conceptions of the meaning of the available fundamental data.

The authors make an especially noteworthy point, that the quantities computed under the detail method may be exceeded under the circumstance of the peak of rainfall intensity becoming synchronized with a large value, CA, of some tributary area. The writer disagrees with the authors in their exclusion of the consideration of this circumstance from the computations.

The study of factors governing the selection of the coefficient of run-off, C, is valuable and will aid in the planning of experiments and analyzing data therefrom. The logic of deriving coefficients of both storage and absorption, as given in Table 7, from the experimental work of Ivan E. Houk, M. Am. Soc. C. E., is not apparent, as the coefficients are distinct from each other and must be evaluated by separate experiments.

---

[23] Asst. Engr., Storm Drain Div., Bureau of Eng., Dept. of Public Works, Los Angeles, Calif.

Comments on the detail rational method of computation regarding, in particular, the method of arriving at the time of concentration by means of varying conduit or channel velocities, bring out several possibilities, namely, that the time of concentration may be equal to the time derived in the detail method or may be much greater, dependent on the slope.

The formula derived for the run-off is built up in an ingenious manner, and is correct under the assumptions. However, some of the assumptions are not always correct, or they are difficult of application.

The assumption of uniform rainfall for the time of concentration is not acceptable for short times of concentration. Examination of storms in Los Angeles for a number of years shows a distinct tendency for the peak rainfall to occur after the middle of the storm. Approximately 70% of the precipitation for 1 hour occurs within an interval of 10 min. The single peak of precipitation will synchronize automatically with the peak of the CA quantities contributing and will produce a higher peak run-off than a uniform rate of rainfall. A large percentage of storm drains built by municipalities falls within the time range of about 60 min. The detail method is as much at fault as the formula method in this respect.

In the derivation of the formula, the factor, F, is based on the conduit running full. The rainfall is assumed to be uniform in intensity for the time of concentration. At each point of concentration above the point under consideration, the uniform intensity is of higher value, and produces a conduit of correspondingly larger capacity per unit net area. The conduit is constructed with a difference of from 3 to 6 in. between sizes. The designer ordinarily selects the higher dimension as a factor of safety; furthermore, where slopes are flat, he selects a conduit to give a minimum velocity to prevent silt deposit; this often leads to an oversize. Losses for curves and structures along the main line must be subtracted from the gross head available in the fall of the surface grades. The result is that for all conduits above the point of concentration, and under the uniform intensity assumption, the friction slope for the full conduit is flatter than the surface grade.

In areas with steep slopes, the pipe will not run full at all points, which makes the value of F incorrect as tabulated. Inspection of the values of F under partly full flow conditions indicates an increased value over that for full flow for closed conduit, and a reverse condition for open-channel sections. In the flatter terrain, where it is possible for back pressure to fill the conduit, the formula is possible of solution with the given tabular values of F. However, to be technically correct, it is necessary, for each point of concentration, that detail tabulation of the friction loss of each length of conduit be made, together with other head losses. An aggravated example of the latter case occurs when an existing storm drain on a flat slope (and subsequently relieved of a part of its normal tributary area by an intercepting drain) is to be examined for capacity under the reduced area. The extreme oversize of the upper part of the conduit makes the application of the formula of doubtful value. A compensating factor, which applies, practically, to all but the last-mentioned case, is the low power of S used in the formula. With proper judgment in selecting S, more correct results are obtainable.

The factor, $P\left(=\frac{v}{V}\right)$, has been tabulated by the authors by a detailed analysis of numerous types of water-sheds. While it is thus arbitrary, a number of tests of the values reveals comparatively small differences from results obtained by detailed analysis, when the value of C is the same for each computation.

The analysis of the factor, C, points to the probability of variation with time and intensity. To handle this variation in the formula, the value of CA must be estimated from a detailed study of the area. On areas containing a large percentage of pervious soil, the study will be difficult, due to the fact that the coefficient of retention varies with the rate of precipitation for any instant of time and not with the average rate of precipitation for a period of time.

The use of the formula for general municipal storm-drain design does not seem advisable. To be able to use it intelligently, the designer must thoroughly understand its derivation and ramifications, and generally must make an analysis equal to that in the detail method. The careful judgment necessary to achieve correct results is likely to be slighted in the desire for a quick answer. The authors do not recommend it for such work. For estimating work, it can be used for shortening time of computations. For bridges and short culverts, the factors of loss other than friction are relatively so much greater, that the formula can be applied for final design.

By using Method No. 2 (which consists of a trial computation assuming a conduit laid up the main channel to the farthermost ridge point), a correction for time determined by an examination of the nucleus (or initial area which has no conduits), and a recomputation with the corrected time in the equation, $Q=CiA$, a quick check can be made at controlling points of the tabling by the detail method.

The purpose of the authors, to construct a formula capable of arriving at a close approximation of the run-off from a large area, has been attained in that the formula more or less duplicates the results obtained by the detailed rational method as now practiced. As set forth in the foregoing remarks, it has certain difficulties of application which require close analysis and more careful judgment in handling than the detail method.

The writer is inclined to give the greater weight to their recommendation following Table 6, urging "a more unified effort on the part of the profession not only toward a thorough analysis of present available data, but also future experimentation along lines following a preconceived plan." Drainage engineers have about arrived at the end of their resources in theory and need data to prove or disprove it.

Carl H. Reeves,[24] M. Am. Soc. C. E. (by letter).—The writer is deeply appreciative of the great amount of work and study shown in this paper. That which stands out most prominently is the logical sequence of the analysis as shown in Part I, and the resultant derivation of the formulas in Part II, bringing to the fore that most important of all factors the determination of *C*, as given in Equation (39).

---

[24] Civ. Engr., Los Angeles County, Los Angeles, Calif.

Engineers have apparently let an innate tendency to worship precedent lead them in the line of least resistance in determining run-off. In other words, they have taken for granted all that has been said and written and have blindly proceeded to apply it to any and all cases without due regard to the facts in any particular case; and by "the facts," it is intended specifically to mention that intensity of rainfall in its relation to the run-off coefficient has been a sadly neglected quantity in many calculations. It would appear that this is the most important factor in determining the value of *C*, or the coefficient of run-off.

Equation (39), with its accompanying explanatory sentences, is so patent that it is difficult to believe that this feature has been neglected or ignored so generally through the years. The application of this one idea alone is a distinct contribution to the Engineering Profession, and will simplify and clarify all long drawn-out and complicated tabulations which have been based on a value of *C* determined only by the presumed best judgment of the designer, or, in many cases, his best guess.

Fundamentally, the rainfall curve as generally used is the "right bower" to the factor, *C*, as determined in this paper. The analysis of the rainfall curve as applied in the so-called rational method is at once both illuminating and the cause of more rational thinking along these lines. As previously mentioned, engineers have been blindly following what they thought was a use of the rainfall curve giving intensities which represented the sequence of an actual storm. It is quite plainly shown that they have not been applying intensities which followed the law of the curve in use.

The writer wishes to congratulate the authors of this paper for the simplification and clarification of the many factors affecting run-off; but, withal, it would be well not to forget the really definite determination of the factor, *C*, as shown in Equation (39). The great benefit that this paper and its deductions will mean to engineers in private practice, railroads, State highway engineers, flood-control officials, and others having to do with an economical as well as a safe design of culverts, watercourses, storm drains, etc., cannot be over-estimated.

JOHN M. KEMMERER,[25] ASSOC. M. AM. SOC. C. E. (by letter).—The writer is interested in the authors' discussion of the use of empirical formulas, which they do not recommend. The paper definitely points out the hazards in the use of such formulas and clearly demonstrates that they are little better than a "rule-of-thumb method."

Factor *C*, based upon experimental data, has always required, and will continue to require, the very best judgment of engineers. Under the heading, "Analysis of Experimental Data," combined with the conclusions, suggestions, and comments of Part I, the authors present a thorough analysis of the factor. Equation (39) should prove useful as time goes on, and as data are collected for analysis.

---

[25] Civ. and Hydr. Engr., Whittier, Calif.

The fact that the run-off coefficient increases with intensity is well illustrated in the paper by Equations (5), (6), (7), (8), and (9). Conclusions (13) and (14), in the writer's opinion, are logically drawn and should receive the attention of engineers, especially those engaged in experimental work.

The analysis leading to Equation (24), a master equation, is clear, and new factors are included, which make it flexible and generally applicable to all areas. The use of this equation and the new factors requires a greater familiarity with the subject of run-off than has been customary with engineers, but this should lead to better professional results.

Messrs. Gregory and Arnold are to be commended and congratulated for the work which they have done in connection with the preparation of their excellent paper. It is manifest that much time and careful thought have been given to the problem. The writer has often felt the need of some ready adequate method of determining run-off and, therefore, commends the authors, particularly for their painstaking work which, in his opinion, has resulted in two distinct contributions: (*a*) The most complete analysis of Factor C yet presented; and (*b*) an equation (Equation (24)) which includes variables not before recognized, is universally applicable, and is rational in derivation.

LEONARD L. LONGACRE,[26] ASSOC. M. AM. SOC. C. E. (by letter).—In the consideration of a new formula the first concern is whether or not the derivation is based on a logical foundation. The formula presented in this paper is derived by starting with the fundamental equation, $Q = CiA$, as used in the detail rational method. The derivation follows in logical sequence until the factors, F and P, are introduced.

There can be no question concerning the velocity in the main flow channel affecting the time of concentration and, consequently, the discharge. The velocity is affected by the shape, and type of the flow channel, and the factor, F, is introduced to allow for this variation. The authors have presented a novel method of determining the value of F.

The writer is unable to explain why $\frac{(c\sqrt{r})^{0.5}}{Q^{\frac{1}{8}}}$ should have a constant value in Equation (18). Factor P makes a sudden and unannounced appearance in Equation (19), and it is unfortunate that the reader must stop and search in separate portions of the paper before an idea may be gained of the authors' intention in introducing this factor.

The arrangement of the collecting channels, which are influenced by the shape of the area, determines the quantity of water flowing at any certain point in the main flow channel. The quantity flowing in the main channel affects the velocity, and, as stated, this affects the time of concentration and discharge. It is evident that Factor P is introduced to allow for this variation in the arrangement of the collecting channels.

The writer is somewhat confused by the discussion just preceding Equation (19). It is evident that the expression, $c\sqrt{r}$, is used first as an abstract quantity to determine the value of N, and then is introduced in Equation (19) as a measure of the average velocity of flow through the main channel.

---

[26] Alhambra, Calif.

With a constant slope the velocity varies directly as the term, $c\sqrt{r}$, which can be expressed as a function of the factors, P and N. In Equation (19) Factor P could then be defined as the ratio of the average quantity flowing in the main channel to the quantity at the outlet. The authors have defined the factor, P, as the ratio of the average velocity in the main channel to the velocity at the outlet. As the velocity varies with the quantity, it can be used as a measure of Factor P as well as the quantity. The method of arriving at definite values of Factor P outlined in the paper is somewhat involved with assumptions. Before a general acceptance of the values of the factor, P, listed in Tables 3 and 4, the Engineering Profession will have to confirm these values in actual use.

It is the writer's opinion that all the factors included in Equation (24) have a direct effect on the run-off, and should be considered in any run-off problem.

The authors have given an adequate discussion on the shortcomings of previous empirical formulas, and have stated forcefully the advantages of their own. The writer does not believe the refinement of computation, as suggested under "Method No. 1," is justified where seven variables are to be chosen. The errors made in the choice of values for these variables will certainly be greater than any accuracy gained by this more elaborate method. Neither does he consider that the formula will replace the detail rational method in the actual detail design of a drainage system.

Its use, as outlined under "Method No. 2," offers possibilities in conjunction with the detail method. Where it is necessary to investigate different combinations of collecting channels to determine which will give the maximum flow, or where it is advisable to investigate whether or not a part of the area may give a greater run-off than the whole, the use of the Gregory-Arnold formula will save considerable time and labor. Another use to which it may be applied is the determination of time of concentration for initial areas.

Where the discharge at certain points in the water-shed is needed for the design of some structure, such as a culvert or bridge, on a stream where no adequate hydrograph is available (and it is seldom that any satisfactory data on rainfall intensity and distribution are available for use in connection with the hydrograph), the formula used, as described under "Method No. 2," will prove a decided benefit over previous methods of computations. It is necessary however, that the proper assumption for rainfall intensity be made. If the correct values of various factors are used in each case, and the run-off coefficient and initial time are placed on the same basis, the results obtained from the formula should compare favorably with those obtained by the detail method, and with a considerable saving in time and labor. The writer has tabled several areas (about 3 000 acres) by the detail method and has compared the discharges and times with those obtained by applying the Gregory-Arnold formula, and he was somewhat surprised at the close agreement, which was within 3 per cent.

In order to save considerable time in computations the writer has prepared a nomograph (Fig. 9), for the general solution of the Gregory-

FIG. 9.—TIME OF CONCENTRATION AND RATE OF RUN-OFF.

Arnold formula. While it is based on a rainfall curve of the type, $i = \frac{K}{\sqrt{t}}$, one can readily be constructed for a curve of any of the general types in present use. The time of concentration has been evaluated as being the factor which is desired in most instances, and from which the quantity can easily be determined. The following example will serve to illustrate the method of use: Let, $C = 0.30$; $A = 10\,000$ acres; $R_1 = 1.23$ in. per hour; $S = 10$ ft. per 1 000 ft.; $F = 4.71$; $P = 0.55$; and $L = 35\,000$ ft. The time of concentration and discharge at the outlet are desired. The product, $CAR_1 = 3\,690$, is beyond the limit of the scale.

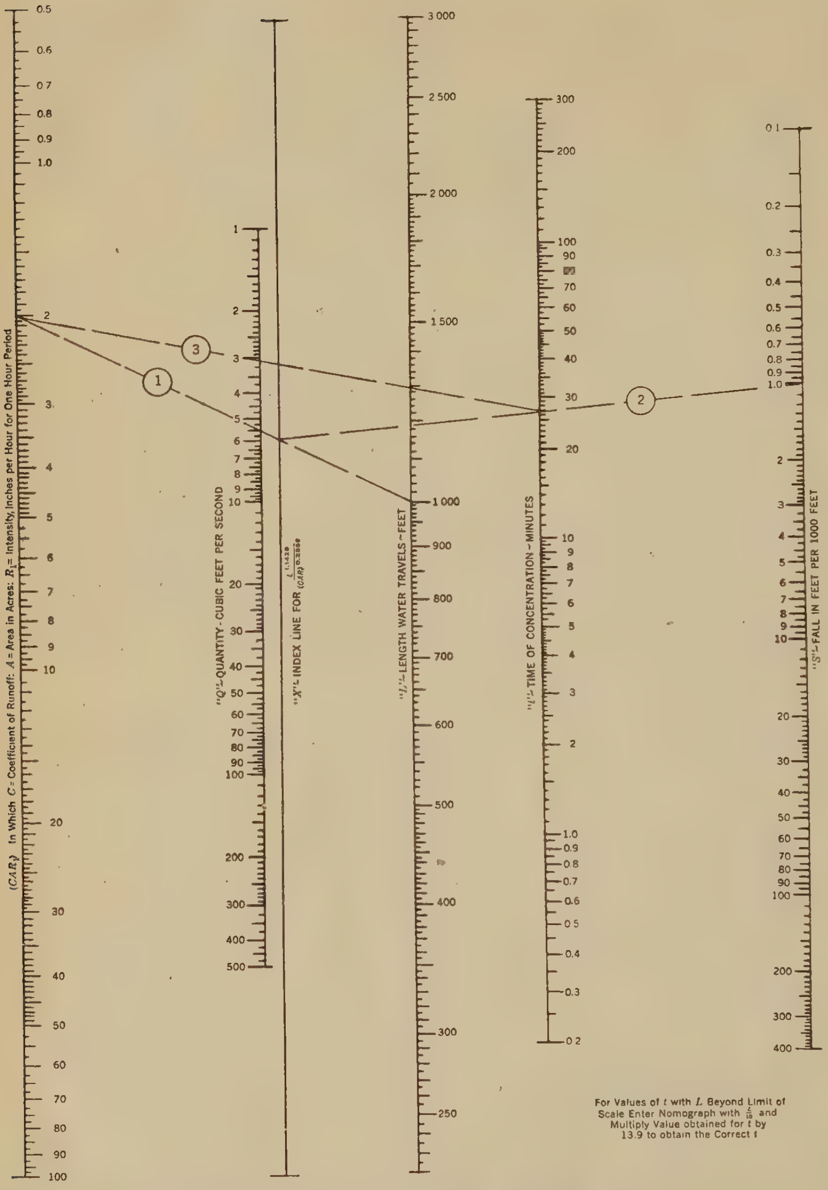
In the note at the bottom of the nomograph are given correction factors to apply for using $\frac{C\,A\,R_1}{1\,000}$. Then enter the CAR_1-scale with the value, 3.69, and, on a straight line connecting this value with 10 on the S-scale, locate the intersection with the index line numbered 3. From this point, on a line connecting 4.71 on the F-scale, locate the intersection with the index line numbered 5. From this point, on a line connecting 0.0000157 on the $\frac{P}{L}$-scale, read the value of 610 at the intersection with the t-scale. This value will be designated as t_1. From this point, at 610 on the t-scale, on a line connecting with 3.69 on the CAR_1-scale, read 1.16 at the intersection with the Q-scale. This value will be designated Q_1. From these values of t_1 and Q_1 the desired time of concentration and discharge are obtained by multiplying by the correction factors as given; thus, $t = 0.139 \times 610 = 85$ min.; and $Q = 2\,683 \times 1.16 = 3\,110$ cu. ft. per sec.

For some time the writer has been aware of the inadequacy of the usual practice of arbitrarily assuming a period of 5 to 15 min. as the time of concentration for the initial area used in the detail rational method. Actual observations have shown that in many cases these assumed times are grossly in error, particularly in flat country where initial times of 25 min. have been observed by the writer, and no doubt even longer inlet times occur. The Gregory-Arnold formula offers a possibility of determining the inlet time of initial areas for use in the detail rational method. The nomograph, Fig. 10, was prepared to facilitate the use of the formula. The numbers in the small circles give the sequence in which the scales are used. Factor F was given a constant value of 5.5 on the assumption that the water running from the most remote portion of the initial area to the point of concentration, would travel most of the way in a concrete gutter. Factor P was assigned a constant value of 0.50 by assuming that the average initial area is a rectangle, the length being twice the width. Another consideration in using a constant value for P is the fact that the percentage of error in the variation of P will be relatively small compared with the error which may occur in choosing the value of C. Where it is advisable to use different values for the factors, F and P, the nomograph shown in Fig. 9 may be used for finding the time of concentration for the inlet areas.

NOMOGRAPH IS BASED ON RUNOFF FORMULA OF GREGORY ARNOLD

$$t = \frac{0.01196\,L^{1.1420}}{(CAR_1)^{0.2856}\,S^{0.4284}}$$

$$Q = \frac{CAR_1\,\sqrt{60}}{\sqrt{t}}$$



For Values of t with L Beyond Limit of Scale Enter Nomograph with $\frac{L}{10}$ and Multiply Value obtained for t by 13.9 to obtain the Correct t

For Values of V with Q Beyond Limit of Scale Enter Nomograph with $\frac{Q}{100}$ and Multiply Value Obtained for V by 3.162 to Obtain the Correct V

FIG. 11.

Equation (50) presents a formula which upon investigation proves to give values agreeing very closely with ones obtained by the use of the Chezy-Kutter formulas when values of $c \sqrt{r}$ are greater than 50. It will prove useful in comparing the hydraulic properties of different types of channels. In Equation (50) replacing Q by $A_x v$, in which A_x is the cross-sectional area, in square feet, of the channel, the resulting formula is:

$$v = 0.3162\, F^{\frac{8}{3}}\, A_x^{\frac{1}{3}}\, S^{\frac{1}{2}} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots (85)$$

In this form, knowing the cross-sectional area of the channel, the velocity can be determined. Equations (50) and (85) can easily be combined on a single nomograph, as given in Fig. 11, and when used in conjunction with a table of F factors, makes possible an easy and rapid solution for the velocity, using either a known area, or quantity, for any channel shape.

In conclusion, the writer wishes to state that he considers the paper worthy of considerable study, and that the reader will be amply repaid for his time by a clearer conception of the fundamentals affecting a rational solution of run-off problems.

G. H. Hickox,[27] Jun. Am. Soc. C. E. (by letter).—The paper should be of particular interest and value to those engaged in the design of storm sewers or land drainage systems having regular outlet channels. Its value lies in eliminating the error, inherent in the common method of analysis, of using a velocity and total time of flow in the outlet channel which do not correspond with the quantity flowing. In considering a storm over a large area, the smaller portions are assumed to be contributing their share at the same high velocity as their own maximum flow. Since the small area contributes to the maximum discharge for the entire area at a lesser rate than its own maximum discharge, the velocity of flow is less. This assumption of too high a velocity leads to shortening the time of concentration, increasing the rate of run-off, and, consequently, increasing the size of outlet channels, which increases their cost. The formulas proposed by the authors should do away with this unnecessary cost and should prove of great benefit.

The formulas should be used with caution on areas greater than 500 sq. miles. Economic and other features being equal, the rainfall curve used for a large area should not be the same as for a small one. The curve for areas of a few square miles may be plotted from records made at points; but when an area of 500 sq. miles is considered, as in Example 7, the curve so made no longer applies. A storm lasting for 4.4 hours with an intensity of 0.933 in. per hour at the point of observation would much less frequently cover 500 sq. miles for that length of time with the same intensity. The rainfall curve made for any point may represent equally well all points within the basin, but unless the intensity for the time of concentration occurs simultaneously at all points—which is extremely improbable on an area of this size—the average intensity on the basin for the period is less than that at the point. Precipitation on 500 sq. miles would necessarily be more intense at some points than at others. As the rainfall curve is made up of the maximum records at points, it follows that an estimate of discharge for the area, based on such a curve, is excessive. Table 15, prepared from data given in Part V of the Technical Reports of the Miami Conservancy District, presents coefficients by which to multiply the maximum precipitation observed within a river basin, to obtain the average over the basin (the values are probably slightly high, as it is assumed that the configuration of the storm coincides with that of the basin).

---

[27] Eng. Coll., Univ. of California, Berkeley, Calif.

TABLE 15.—RATIO OF AVERAGE RAINFALL OVER A GIVEN AREA TO MAXIMUM OBSERVED RAINFALL WITHIN THE AREA, FOR STORMS OF 1-DAY'S TO 5-DAYS' DURATION.

Drainage area, in square miles.	Coefficient.	Drainage area, in square miles.	Coefficient.
0	1.00	4 000	0.76
500	0.90	6 000	0.72
1 000	0.86	8 000	0.70
2 000	0.82	10 000	0.67

The writer is not convinced that the rational formula is ready to displace the empirical formula for the estimation of floods. Empirical formulas are subject to much abuse, being used far afield from the data on which they are based. It is the indiscriminate use of empirical formulas by engineers not familiar with their derivation and limitations, which has brought them into their present disfavor. An empirical formula for the 50-year flood, carefully based on data obtained in the vicinity where it is proposed to be used, and applied only within the range of these data, or moderately extrapolated, is probably superior to the rational formula. The element of frequency enters in connection with economic considerations, as it is seldom economical to design for the absolute maximum. The engineer is not so much concerned with the maximum flood as with that flood which may be expected once in, say, 50 years.

The rational formula assumes an average rainfall over the time of concentration and a uniform distribution over the basin. In general, floods are not produced by these conditions. They are the result of intense localized storms lasting for a fraction of the time of concentration; light, warm rains on snow-covered, frozen ground; and, occasionally, the conditions postulated by the formula. If these conditions, however, only produced the 50-year flood, it would still be impossible to evaluate it on the basis of the 50-year rainfall because of the uncertainty in the value of the run-off coefficient. On stream basins in the Middle West, the value of *C* may vary more than 100% for summer rainfalls of the same average intensity, due solely to the difference in saturation of the soil. Evidently, only a fraction of the 50-year rainfalls produce 50-year floods, as the soil is more often than not insufficiently saturated to produce maximum run-off. The problem is further complicated by the occurrence of floods due to intense local storms and the spring floods due to melting snow. The empirical formula, however, being based on recorded floods, automatically considers all these factors and groups them into two or three coefficients and exponents.

The Iowa River Basin above Iowa City, Iowa, may be taken as a fair example for comparison of rational and empirical formulas. Its drainage area is 3 140 sq. miles; channel length, 261 miles; and average slope, S, 0.425. The value of P may be taken as 0.65 and that of F as 4.0. The time of concentration is approximately 100 hours. Estimating the 50-year rainfall intensity from the charts[28] prepared by Merrill M. Bernard, M. Am. Soc. C. E., $i = \frac{75}{t^{0.8}}$, or, for 100 hours, $i = 0.0712$. Multiplying this by a factor taken from Table 15, $i = 0.78 \times 0.0712 = 0.0555$. The value of C for the Iowa River Basin is probably in excess of 0.35. Using these values, Equation (24) gives a discharge of 34 200 cu. ft. per sec.

F. A. Nagler, M. Am. Soc. C. E., has proposed[29] an empirical formula,

$$Q = 210\, M^{\frac{2}{3}} \quad \text{.........................} (86)$$

for the magnitude of the 50-year flood to be expected on Iowa streams, in which, Q is the discharge, in cubic feet per second, and M is the drainage area, in square miles. By Equation (86), the discharge is 45 000 cu. ft. per sec. Floods greater than 35 000 cu. ft. per sec. have occurred three times at Iowa City since 1850, the largest being 50 000 cu. ft. per sec. The discharge given by the empirical formula is seen to fit at least as well as that by Equation (24) (which, in this case, is 24% less), and to involve much less labor.

The maximum average precipitation on the Iowa River Basin is probably about 10 in. in 4 days, or approximately 0.1 in. per hour for 100 hours. With $e = 0.8$ and $C = 0.4$, the maximum flood as given by Equation (24) is 84 400 cu. ft. per sec., a flood which is 88% greater than the 50-year flood and obviously beyond the ordinary considerations of economic design.

DONALD M. BAKER,[30] M. AM. SOC. C. E. (by letter).—The ready acceptance and use of familiar methods and formulas in design and computations, without an intelligent consideration of the limitations to which such formulas are subject, is a practice too common among engineers. A paper such as this, wherein the influences affecting the different factors embraced in the formulas used in the calculation of storm-water run-off are discussed and analyzed, is a decided service. The design of any storm drain system is a complicated process at best, involving many assumptions and a considerable degree of engineering judgment.

The master formula, Equation (24), is a considerable improvement. It goes much farther than older formulas in the inclusion of variables by the addition of terms representing changes in slope and consequent velocity of the main channel above the point of concentration, shape and roughness of this channel, and length and shape of the water-shed. It also allows greater flexibility in determining the period for the selection of the intensity and the variation in type of rainfall curve used. While it is somewhat complicated, nevertheless, in any organization in which much work of this type is done, its use can be facilitated by the development of curves or nomographs.

---

[29] "Survey of Iowa Floods," *Proceedings*, Iowa Eng. Soc., 1928.

[30] Cons. Engr., Los Angeles, Calif.

Of the three factors expressing the fundamental relationship between run-off and rainfall, stated by the authors in the expression, $Q = C\,i\,A$, the area, A, may be determined with a high degree of accuracy, and the intensity of rainfall, i, expressed in inches per hour (or the rate of contribution of water to the water-shed by precipitation, expressed in cubic feet per second per acre), may be ascertained with approximate accuracy in most localities where storm drain systems of any magnitude are to be constructed. Nevertheless, where the formula is to be used in the determination of storm or flood flows, in mountainous sections, or where precipitation records are lacking, much may be left to judgment or imagination.

However, it is the factor, C, which affords the opportunity for widest variation in the use of judgment. General reference to this factor in textbooks and technical papers seems to be based largely upon arbitrary assumptions or upon some previous reference and not upon results of actual experience. No one can give this subject much attention without being impressed with the paucity of experimental work carried on to establish values for this factor. Storm drain systems are expensive; a complete drainage system in a residential section, designed for a reasonable frequency of excessive precipitation, may cost $500 to $1 000 per acre, or $320 000 to $640 000 per sq. mile, or even more. The cost of such system, other things being equal, varies directly with the cost of pipes or box-drains used to carry the water, and this, in turn, varies approximately in a direct ratio with the quantity of estimated flood flow, which varies directly with the factor, C. It can readily be seen, therefore, that a variation of 10% in the value of C (say, where it was assumed as 0.45 instead of 0.40, due to lack of definite knowledge) might result in a variation in the cost of a drainage system of from $50 to $100 per acre, or $$32 000 to $64 000 per sq. mile. In the light of this, it is surprising that more communities engaged in large programs of storm drain construction have not embarked upon a program of investigations of values for this factor. Nothing like the amount of research has been given to it as to the determination of such factors as proper values for Kutter's n, or constants in weir formulas. Such experimentation should logically be done by a governmental agency, in order that the results obtained could be made widely available. However, there does not appear to be such an agency in the Federal Government which could logically be considered as interested in this subject.

The mathematical proof which the authors offer in substantiation of their conclusions regarding variation of C with intensity, etc., is of considerable interest, and increases the confidence with which these conclusions may be used. A further feature of interest is the derivation of Equation (39), indicating the manner in which the rate of run-off varies with intensity of precipitation. In this equation, m expresses such influences as roughness of the ground surface of the water-shed, and the retarding effect of vegetal cover. Interception of precipitation by trees and brush, or its storage in a mulch of leaf mould, or in a dense grass cover, may result in the collection of a considerable quantity of precipitation, until saturation occurs and allows run-off to proceed. A few investigations along these lines have been made by experimenters interested in irrigation development and in the protection of water-sheds against fires. The quantity, z, used in Equation (39) is influenced principally by the soil type and the slope of the ground surface. During a visit, the writer was impressed by the lack of evidences of surface erosion on the floor of the Valley of Mexico as well as in Florida. Storms of high intensity and rather prolonged duration occur in these localities, but the soil appears to have such a high absorptive capacity that run-off is not evident. Some sandy soils, however, do not have this high capacity, due probably to lack of uniformity of size of grains.

The slope of the ground surface affects the rate at which the surface water concentrates in the small drainage channels and travels in them, but it also affects absorption or percolation. Equation (39) shows that as long as the rate of absorption is greater than the rate of precipitation, or when $z > i$, the factor, C, is a negative quantity, since $m < 1$ and no run-off can occur. When $i > z$, however, a surplus collects, which produces run-off. With flat slopes, velocity of run-off is decreased, depth of run-off is increased, and the resultant head of water on the soil surface also is increased. Using the same nomenclature as the authors,

$$Q = k\,(i - z') \qquad \text{(87)}$$

in which, $k =$ a constant, and $z' =$ maximum unit rate of absorption by soil without superimposed head, constant for any given soil and surface condition; but Q varies as vd.

Let $v =$ velocity; $d =$ depth of water flowing over soil; and $k' =$ a constant; then,

$$Q = k'\ vd = k'\ dc\ r^{\frac{1}{2}}\ s^{\frac{1}{2}} \qquad \text{(88)}$$

Since $r = d$, approximately, Equation (88) reduces to,

$$Q = k'\ d^{\frac{3}{2}}\ c\, s^{\frac{1}{2}} \qquad \text{(89)}$$

Therefore, $k\,(i - z') = k'\ d^{\frac{3}{2}}\ c\ s^{\frac{1}{2}}$, and,

$$d = \left(\frac{k\,(i - z')}{k'\ c}\right)^{\frac{2}{3}} \frac{1}{s^{\frac{1}{3}}} \qquad \text{(90)}$$

Let $z'' =$ rate of percolation from run-off, and $k'' =$ a constant. Then, since the rate of percolation also varies as the superimposed head,

$$z'' = k''\ d = k''\left(\frac{i - z'}{c}\right)^{\frac{2}{3}} \frac{1}{s^{\frac{1}{3}}} \qquad \text{(91)}$$

and, $z = z' + z''$, which shows that induced absorption, as distinguished from the natural absorption rate of the soil, varies directly with the two-thirds power of the difference between the rate of precipitation and the natural absorption rate of the soil, and also increases directly in a certain manner with the surface roughness, but increases inversely with the cube root of the slope.

In explanation of the fact that a zero value of s would make z'' approach infinity, it may be stated that this relationship only holds when the velocity of flow of the run-off follows the Chezy-Kutter formula.

ALBERT R. ARLEDGE,[31] ASSOC. M. AM. SOC. C. E. (by letter).—The authors, undoubtedly, have presented a more complete analysis of the subject with which they deal than may be found elsewhere. The paper constitutes a distinct contribution to the profession in each of the two parts into which it is logically divided.

Part I subjects existing methods of estimating the probable maximum run-off of a given area to an orderly and critical analysis, enabling the reader to visualize the many possible variations of the several factors involved. In so doing it brings to light some basic principles which seem to have been entirely neglected by those who have written about the rational method of computing run-off.

Among the hitherto neglected principles may be mentioned: (*a*) Use of the velocities in determining time in the detail method, which do not obtain under the assumptions; and (*b*) the effect on the run-off coefficient of a change in intensity.

The latter principle is by far the more important, especially for the consideration of water-sheds containing considerable pervious area. The simple nature of this phenomenon (after its able presentation by the authors), which may so vitally alter the resulting run-off, causes one to wonder why so many able writers on the method have overlooked it. Although it makes the estimation of run-off by the detail process more tedious, its effect, once understood, should certainly be recognized. The "Suggestions (*a*) and (*b*)," and "Comment" forming the conclusion of Part I, may well be heeded by engineers who find it advisable to use the detail process.

Part I, as a whole, should serve the Engineering Profession as a valuable reference for study by those of its members who contemplate the solution of maximum storm flows regardless of the method subsequently adopted.

In Part II of their paper, the authors present run-off formulas which are entirely logical in derivation, as far as the writer is able to determine. It would seem that their presentation at this time, goes far toward satisfying a need of many engineers for a quick and direct method for applying rational principles to the solution of discharges for the larger areas. In this connection attention should be called to (*a*) the paper[32] by Merrill M. Bernard, M. Am. Soc. C. E., together with subsequent discussions thereof; (*b*) treatment[33] of this subject by Harrison P. Eddy and the late Leonard Metcalf, Members, Am. Soc. C. E.; (*c*) discussion[34] by Charles H. Lee, M. Am. Soc. C. E., of the paper by Oren Reed, Assoc. M. Am. Soc. C. E.; and (*d*) writings by others in the general literature on the method.

The saving of time through use of the formulas, as compared with that of the detail process, will naturally depend not only on the nature and extent of the areas, but also on the purpose of the engineer. Generally, the time saved will vary with the size of the area above the point at which discharge is sought. It is unfair, therefore, to compare these formulas (without any qualifications) solely with the detail method of estimating storm flow for a small city drainage system, wherein the discharge is sought at every inlet point. Even for small areas (and likewise for any irregular area) the formulas should prove time savers in making trials for the determination of run-off from water-sheds, a part of which will render a greater value under the assumptions, than the whole.

---

[31] Asst. Engr., Los Angeles Bureau of Power and Light, Los Angeles, Calif.

[32] See p. 592.

[33] "American Sewerage Practice," Vol. 1, Second Edition, pp. 305–306.

[34] *Transactions*, Am. Soc. C. E., Vol. 93 (1929), p. 433.

Equation (39) deserves special mention. This formula appears to embody the culminating thoughts of the authors, in their analysis of the run-off coefficient, especially as regards future experimentation. Indeed, it would seem that the "rational method" should scarcely be called rational without possession of Equation (39), or its equivalent; and it should prove valuable in future experimentation which contemplates the use of any method for calculating discharges.

In conclusion, the writer wishes to state that the authors deserve the appreciation of the profession, not only for the great energy and thought necessarily required for the creation of their paper, but also for the actual value of the gift itself. The analysis, conclusions, and formulas therein, will be referred to in the future. The future worth of the formulas will depend largely on the amount of intelligent use to which they are subjected.

CLARENCE S. JARVIS,[35] M. AM. SOC. C. E. (by letter).—The authors have made a clear exposition of many fundamental principles and considerations related to stream flow, and have attempted a somewhat rigorous analysis, evaluation, and correlation of various factors for practical use. So much of the textual treatment is commendable and beyond challenge that it is with reluctance that the writer registers minor exceptions or divergent views.

Having deliberately and repeatedly approached the subject of run-off, together with the derivation and critical tests of the best-known formulas, with an open mind, ready to accept or to reject any and all according to practical results within the fields for which data are available, he is unable to concur in either Considerations (1), (2), and (3), under "Empirical Formulas," or Statements (*d*) and (*e*) under "Inadequacy of Empirical Formulas." Do they not actually express the summation of all the influences mentioned in the paper under discussion, based on observed behavior instead of on *a priori* reasoning? While according an important place for the profitable application of the so-called rational method of analysis, one must likewise recognize its inherent limitations, disadvantages, and defects. Where detailed information is lacking on extensive water-sheds, the empirical formulas and high-water marks of past years will doubtless continue as the main reliance for purposes of design. Before the requisite mass of data can possibly be collected regarding physiography, topography, soils, channel characteristics, and rainfall habits, there will be many occasions for measuring the stream discharge and some part of the precipitation that preceded the gauging.

"The storm causing the greatest rate of discharge in a storm sewer will usually be the maximum rain lasting a length of time equal to the time of concentration" is the original form of the statement published[36] by Anson Marston Past-President Am. Soc. C. E., in 1909, which has had great influence in guiding recent investigations. It is obvious that detailed analyses and tabulations are facilitated by the convenient assumptions that have been added as to "maximum uniform intensity" and, also, equal simultaneous distribution over large water-sheds during the time of concentration; but those assumptions are largely contrary to usual rainfall habits, especially over extensive drainage areas. Neither is the maximum rate of run-off necessarily the result of simultaneous contributions from all parts of the water-shed. It is more likely the result of an intense down-pour and concentration from a considerable portion, while much of the remaining area yields only a negligible run-off.

---

[35] Prin. Hydr. Engr., U. S. Engr. Office, War Dept., Washington, D. C.

In keeping with the name usually accorded, the rational method should exclude such an expression for rainfall intensity as appears in Equation (2), which is capable of bringing forth absurdly high intensities for very short periods of time. Evidently, a constant should be added in the denominator to make it a safe factor as in Equation (45). Adolph F. Meyer M. Am. Soc. C. E., has recommended,

$$i = \frac{A\,t}{t + B} \quad \dots\dots\dots\dots\dots\dots\dots\dots (92)$$

in which, both A and B are constants.[37] Furthermore, the introduction of N as a constant, based on a chance relation of certain variables within restricted range, may account for larger errors or irregularities than would be contemplated from Equation (18); for, in Equation (32), both the constant and the percentages are squared, and this would more than double the positive errors; for example, 1.10 × 1.10 = 1.21. Also, the varying channel sections, gradients, and velocities to be found in practically all natural drainage systems are quite contrary to the assumptions of the authors, who seem to be carrying the storm drainage conduits throughout the water-sheds under consideration. Otherwise, it is almost inconceivable that such velocities as 28.3 ft. per sec., or 19 miles per hour, would occur with the slope and discharge assumed in Example 3.

It seems to be contrary to experience that the instantaneous discharge at a given station should vary directly with the length of travel. Perhaps the total quantity bears such a relationship; but the increased time of travel affords opportunity to smooth out the flood crests, thus increasing channel storage, underflow, and period of high stage. If a linear dimension is desired instead of some function of the drainage area, the average width seems to have a more logical basis for adoption, as has been demonstrated[38] by Charles R. Pettis, M. Am. Soc. C. E.

The discharges of 1 006 and 1 069 sec-ft. from 2.02 sq. miles, as used in Examples 6 and 8, respectively, are equal to 7.1% and 7.5% on the Myers scale[39]; while the 59 740 and 62 003 sec-ft. from 500 sq. miles, as disclosed in

---

[36] Cyclopedia of Civil Engineering, Vol. VII, 1909, p. 305. "Sewers and Drains."

[37] "Elements of Hydrology, Precipitation," 1928, p. 103.

[38] "A New Theory of River Flood Flow," by Charles R. Pettis, M. Am. Soc. C. E.

[39] *Transactions*, Am. Soc. C. E., Vol. 89 (1926), p. 994.

Examples 7 and 9, represent 26.7% and 27.8%, respectively. Taking into account the time required for a reliable solution by small increments from individual areas, the many estimates, assumptions, and uncertainties involved, the acurate knowledge of the water-shed topography, geology, soil characteristics, and rainfall habits, that must be in hand for reliable results, and the involved factors and nomenclature required for the method presented in the paper, it appears that its special field for usefulness is in urban and metropolitan developments. To the writer the best of the empirical formulas seem better adapted to large areas and to the determination of run-off therefrom; and they seem to have fully as valid a claim to the descriptive adjective as has been shown for the "rational formulas" under discussion.

It is significant that the expression adopted by the Committee on Floods of the Boston Society of Civil Engineers,[40] readily reduces to a form comparable with the modified Myers formula,

$$Q = 10\,000 \times 80\% \sqrt{A} \quad \ldots\ldots\ldots\ldots\ldots\ldots(93)$$

thus ranging up to a rating of 80% for maximum floods during long periods of time.

Notwithstanding the implication so often expressed to the effect that such formulas do not take account of the shape and other variable characteristics of drainage areas, the estimated effects of such factors are readily incorporated in the percentage adopted. Thus, with ratios of length to width represented by 5, 2, and 1, the flood rating for a given water-shed and frequency of recurrence might be 50%, 60%, and 80%, respectively.

The platting of observed rainfall and run-off with time and average depths on the water-shed as co-ordinates, together with detailed studies of soil, slopes, vegetative cover, and geology along with physiography, should afford a fair index to probable stream flow from a given area, or from other water-sheds with similar characteristics, and there is a definite and important place for both the rational and the empirical methods of analysis.

C. E. GRUNSKY,[41] PAST-PRESIDENT, AM. SOC. C. E. (by letter).—As long ago as 1908 the writer attempted a mathematical demonstration of the propriety of using a rational formula for the determination of the maximum rate of run-off (maximum stream flow), based on the maximum rate of rainfall or maximum rain intensity. In the paper[42] describing that work it will be seen that as a basis for the mathematical presentation the fact was taken into account that the water which falls as rain—in any period of time that may come under consideration when the maximum rate of run-off at some selected point is to be estimated—must (at the peak of discharge) either have already passed the point in question or must still be in temporary storage: (1) As a film of water on the surface; (2) as water in conduits; (3) in watercourses; or (4) in lakes and reservoirs within the water-shed tributary to the point. Loss by evaporation in the consideration of small areas and short critical periods may be neglected or rather merged with the other factors that go to make the maximum run-off rate less than the maximum rate of fall of water upon the water-shed as rain.

---

[40] *Journal*, Boston Soc. of Civ. Engrs. (1920), Vol. VII, p. 47.

[42] "The Sewer System of San Francisco, and a Solution of the Storm-Water Flow Problem," *Transactions*, Am. Soc. C. E., Vol. LXV (1909), p. 294 *et seq.*

In the resulting analysis local records of heavy rainfall were necessarily taken into account and, of course, also the formulas for maximum rain intensity based thereon. These formulas determine the total quantity of water which may be precipitated upon any water-shed during the continuance of the rain which produces maximum stream flow.

Account was then taken of water-shed characteristics, such as extent, shape, topographic and orographic features, the degree of permeability of the surface, etc. These characteristics serve as a basis for approximating the critical time applicable to the water-shed; that is, the time within which a maximum downpour would produce maximum stream flow. It was assumed that this time would be that period which would elapse from the beginning of the rain until all essential major portions of the water-shed were contributing run-off to the stream at the point for which maximum stream flow is to be determined.

In 1930, the writer published simplified rain-intensity formulas.[43] These result in part from the substitution of the hour for the minute as the unit of time. These new formulas are intended to permit closer approach to actual fact, both for precipitation during very short time periods, ½ hour, or less, and during very long periods. The suggested refinement for very short time periods is of value mainly when a short time record must be used in determining formula constants for any locality; otherwise, it is of no particular importance.

The intensity of rainfall is never uniform throughout any time period. It is not uniform at all points in a water-shed at any particular instant. Neither is the aggregate amount of rain during any period uniformly distributed. Nevertheless, the intensity of rainfall which will naturally be introduced into any rational formula for maximum storm-water discharge is the maximum average intensity throughout the water-shed, during the time which intervenes from the beginning of a storm of the type which will produce maximum discharge to the instant when this maximum discharge occurs.

This time, called for convenience "the critical time," must be determined, as already stated, from water-shed characteristics. When the water-shed has a compact, fairly regular form without long finger-like distortions, it will approximate the time that it takes water, in quantity, to flow from the remote parts of the water-shed to the point of concentration. Ordinarily, it must be left to the good judgment of the engineer to make a fair approximation of this period. This time as well as the rain intensity being in the nature of the case approximations, it becomes evident that great refinement in computation is less important than good judgment in evaluating basic elements. Frequently, in the case of large water-sheds the maximum discharge results from rain on a fractional part only of the entire water-shed.

---

[43] *Monthly Weather Review*, October, 1930; and, *Military Engineer*, May-June, 1931; also, p. 612.

It may be noted in passing that it is inadvisable to use any of the well-known older types of formulas for maximum stream flow, which do not include rain intensity as a factor.

The writer favors his own rain intensity and run-off formulas of which the former have already been presented to the Society.[44] For convenience they are here repeated with adherence so far as practicable to the author's notation:

For $H < 0.33$ hour (20 min.):

$$X_{\text{max.}} = 0.75\,K\,H^{\frac{1}{4}} \tag{94}$$

$$i_{\text{max.}} = \frac{0.75\;K}{H^{\frac{3}{4}}} \tag{95}$$

For $H > 0.33$ hour and < 64 hours:

$$X_{\text{max.}} = K\,H^{\frac{1}{2}} \tag{96}$$

$$i_{\text{max.}} = \frac{K}{H^{\frac{1}{2}}} \tag{97}$$

For $H > 64$ hours:

$$X_{\text{max.}} = 2\,K\,H^{\frac{1}{3}} \tag{98}$$

$$i_{\text{max.}} = \frac{2\;K}{H^{\frac{2}{3}}} \tag{99}$$

If now the maximum rain in 1 hour be represented by R, instead of by the author's notation, $X_1\,(_{\text{max.}})$ it will appear from Equations (96) and (97) — because $K = X_1\,(_{\text{max.}}) = i_1\,(_{\text{max.}})$—that the value of K is the maximum rain in 1 hour and $K = R$. Equations (94) to (99), inclusive, may therefore be written:

For $H < 0.33$ hour:

$$X_{\text{max.}} = 0.75\;R\;H^{\frac{1}{4}} \tag{100}$$

$$i_{\text{max.}} = \frac{0.75\;R}{H^{\frac{3}{4}}} \tag{101}$$

For $H > 0.33$ hour and < 64 hours:

$$X_{\text{max.}} = R\,H^{\frac{1}{2}} \tag{102}$$

$$i_{\text{max.}} = \frac{R}{H^{\frac{1}{2}}} \tag{103}$$

For $H > 64$ hours:

$$X_{\text{max.}} = 2\,R\,H^{\frac{1}{3}} \tag{104}$$

$$i_{\text{max.}} = \frac{2\;R}{H^{\frac{2}{3}}} \tag{105}$$

---

[44] See p. 612.

When the value of $K = X_1\,(_{\text{max.}}) = R$ is to be determined for any area, the actual maximum precipitation on that area, during some period approximating the critical time, should be used as the basis for this determination. The necessary computation can then readily be made with the aid of the appropriate one of the three Equations (100), (102), or (104).

In any area of considerable extent the maximum average rain intensity on the entire area will be less than at single points of heavy rainfall. The maximum intensity is not coincident in time at all points of the water-shed. The precipitation of water upon a water-shed in the form of rain is at a more rapid rate than the run-off. Not all the water which falls upon a water-shed will reach the stream or other drainage conduit. Some of it sinks into the surface formation and ultimately either evaporates or remains underground so long before re-appearing in springs that its effect upon the maximum stream flow is lost.

Therefore, some modification factor with a value less than unity will have to appear in any formula for maximum stream flow if based on maximum rain intensity. Let α (the a in the writer's formulas published elsewhere) represent this modification or water-shed factor dependent upon surface characteristics and the extent of the water-shed; and let q represent the maximum run-off rate or maximum stream flow, in second-feet per square mile of water-shed area.

One acre-inch of rain is equivalent to $\left(\frac{43\ 560}{12} =\right)$ 3 630 cu. ft. of water.

Consequently, if 1 in. of rain falls on 1 acre in 1 hour (= 3 600 sec.) and if all the water should run off at the rate of the rainfall, then this rate of run-off would be $\frac{3\ 630}{3\ 600} = 1.0$ cu. ft. per sec. In round numbers, therefore, 1 in. of rain in 1 hour on 1 sq. mile, or 640 acres, if all ran off in 1 hour, would be equivalent to a flow of 640 sec-ft.

Not all the rain which falls on a water-shed in the critical period, even when falling on an impervious surface, will appear as run-off during this period, or in any other period of equal duration. There will be some loss, as stated previously, and there will be a greater quantity of water in transit, that is, in temporary storage, at the end of any critical period than at the beginning of the period. It will suffice for practical purposes to take this reduction in the quantity of discharge compared with the quantity of rain water at about 25% and to assume, therefore, that actual run-off per square mile in the critical period, when the rain intensity is 1 in. per hour, will be about (75% of 640 =) 480, or, in round numbers, say, 500 sec-ft. per sq. mile instead of 640.

Because the value of $X_1\,(_{\text{max.}})$, or R, which represents the maximum rainfall on the water-shed in 1 hour, may be substituted for the coefficient, K, and because t, expressed in hours, is now to be written for H, the time of concentration (the critical time), the formulas for maximum run-off per square mile will take the form:

For $t < 0.33$ hour:

$$q = \frac{375 \quad \alpha \quad R}{t^{\frac{3}{4}}} \qquad \text{(106)}$$

For $t > 0.33$ hour and < 64 hours:

$$q = \frac{500 \quad \alpha \quad R}{t^{\frac{1}{2}}} \qquad \text{(107)}$$

For $t > 64$ hours:

$$q = \frac{1\,000 \; \alpha R}{t^{\frac{2}{3}}} \qquad \text{(108)}$$

If A_m represents the area of the water-shed, in square miles, and $Q_{\text{max.}}$, the maximum rate of discharge, in second-feet, then:

For $t < 0.33$ hour:

$$Q_{\text{max.}} = \frac{375 \quad \alpha \quad R \, A_m}{t^{\frac{3}{4}}} \qquad \text{(109)}$$

For $t > 0.33$ hour and < 64 hours:

$$Q_{\text{max.}} = \frac{500 \quad \alpha \quad R \quad A_m}{t^{\frac{1}{2}}} \qquad \text{(110)}$$

For $t > 64$ hours:

$$Q_{\text{max.}} = \frac{1\,000 \; \alpha \; R \, A_m}{t^{\frac{2}{3}}} \qquad \text{(111)}$$

In some cases, the value of the coefficient, α, may be determined from known (measured or closely approximated) high rates of discharge and the rainfall characteristics which produced these rates. Generally, however, assumptions must be made relating to this value. It appears obvious that of the total quantity of water falling on a water-shed as rain, the relative quantity which evaporates, together with that which sinks into the ground and is thus prevented from contributing to the peak discharge, increases as the critical time (that is, as area) increases.

This consideration has led to the tentative adoption of the following expression for α and the selection of values for surface characteristics which may be used until something better is offered for typical localities:

$$\alpha = \frac{1}{1 + \beta \sqrt{t}} \qquad \text{(112)}$$

in which, β is a factor dependent on the surface conditions of the water-shed. For the present:

$\beta = 0.013$ for impervious areas.
$\beta = 0.25$ for mountains.
$\beta = 0.40$ for rolling country.
$\beta = 1.3$ for flat country (ordinary soil).
$\beta = 6.5$ for sandy regions.

These values are suggested for ordinary conditions in temperate climates. The resulting values of the coefficient, α, will be found, no doubt, too small in localities where the ground may be frozen, where it is water-logged, or where the maximum run-off occurs when heavy rains fall on snow.

The intensity of rainfall under extreme conditions is now fairly well known throughout the United States for individual stations. It is not so well known what the maximum rainfall in a limited time period may be throughout water-sheds of considerable extent. The rain intensity at single stations may quite properly be accepted as applying to small areas. For large areas the mean maximum rain intensity will be materially less than the maximum rain intensity on small areas.

For convenience, it may be assumed that for a critical time period of 1 hour, or less, the rainfall throughout the entire water-shed under consideration will be of the same intensity as at single stations.

For longer critical periods and larger water-sheds the maximum rain intensity (computed as if the rain were distributed uniformly over the area in question) will be based on the best meteorological data available. Its determination throughout any water-shed in question during the critical time, t, is best made from actual records of heavy rainfall and a study of its distribution to the various parts of the water-shed. Such records, however, will rarely, if ever, indicate the true possible maximum. Consequently, some correction factor greater than unity must be applied, based on a comparison of the individual station records during such a storm with the possible local maxima. It should not be assumed, however, that rain of maximum intensity will occur at all the stations at the same time, but rather that if the storm in question at controlling stations might have produced an intensity greater by some percentage, then it is proper to assume that with similar relative distribution of rain throughout the water-shed some future storm might produce the same proportionally greater amount of rain and of run-off.

Due to topographic and orographic characteristics of the water-shed, coupled with the distribution of the rain throughout its extent, it will frequently be found, as already stated, that a rainfall of maximum intensity on a part of the water-shed during a relatively short critical period will produce a greater peak discharge than that which occurs when the rain of maximum intensity for the longer critical time applicable to the entire water-shed is taken into account. Trial computations alone, in the light of rainfall data, can determine what part of the river system is to be excluded in making the estimate of maximum momentary river discharge.

The method of estimating the maximum stream flow can now be summarized briefly as follows:

(*a*) Determine the critical period for the water-shed, with a proper allowance for the time that it will take water to flow in the stream from the water-shed to the point at which maximum stream flow is to be ascertained. Express this critical time, t, in hours.

(*b*) Determine the value of the water-shed coefficient, α, from the surface characteristics of the water-shed by use of Equation (112).

(*c*) Determine from the rainfall records, the maximum depth of rain, expressed in inches, which has fallen upon the water-shed in any period, about t hours in duration, and with the aid of single station records by means of a correction factor establish the probable maximum rainfall on the water-shed in t hours. This maximum and the critical time will establish the maximum intensity for the water-shed and this, in turn, will be used in calculating the value of R ($= X_1$ ($_{\text{max.}}$)) applicable thereto. The contribution by the authors on this subject of a determination of the critical time should be found helpful.

(*d*) Use Equations (106), (107), or (108), as the case calls for, to determine the maximum flow, in second-feet per square mile, or Equations (109), (110), or (111) to determine the maximum stream flow, in second-feet, at the point under consideration.

It remains to be said that lakes and reservoirs are frequently factors which prolong the critical period and reduce the maximum stream flow. Ordinarily, their effect is fairly well taken account of in the estimate of the duration of the critical period. When, however, the point for which maximum flow is to be determined lies close below a large lake or reservoir, recourse may have to be had to a special study of the effect of the increase of storage in such a water body upon the discharge at the peak of the flood flow.

The following examples will illustrate the application of the formulas:

Example (*1*).—Let it be supposed that for a mountainous water-shed of 2 000 sq. miles, the critical time, that is, the value of t, has been approximated at 36 hours. The most severe storm of which there is record, as indicated by a number of rain gauges and by the resulting isohyets, produced an average of 4 in. of rain throughout the water-shed during this period. However, it is known that all single-station records for this storm have been, or may have been at some time, exceeded by 50 per cent. What should be assumed as the probable maximum stream flow?

Because single-station records have been exceeded it is probable that the maximum measured rain intensity throughout the water-shed should be increased in like proportion. Instead of 4 in., therefore, 6 in. should be introduced in the calculation. Equation (107) will apply.

It follows that: $i_t = \frac{6}{36} = 0.167$ in. per hour, the average for the 36 hours; and $i_t = \frac{R}{\sqrt{36}} = 0.167$. Therefore, $R = 1$ (determined in this case directly from the rain on the entire water-shed; not from any single-station record).

From Equation (112):

$$\alpha = \frac{1}{1 + 0.25 \sqrt{36}} = 0.40$$

and from Equation (107):

$$q = \frac{500 \times 0.40 \times 1}{\sqrt{36}} = 33 \text{ sec-ft. per sq. mile}$$

and,

$$Q_{\text{max.}} = 2\,400 \times 33 = 80\,000 \text{ sec-ft.}$$

Example (*2*).—In a down-town area having an extent of 20 acres, or 0.0313 sq. mile, 70% of the area is impervious; the remainder is ordinary soil. The critical time is estimated at 15 min. (= 0.25 hour). The maximum rainfall in 1 hour is known to be 3 in. What will be the maximum rate of run-off from this area? Use Equation (106). Here,

$$R = 3;\ i_{\text{max.}} = \frac{0.75\,R}{0.25^{\frac{3}{4}}} = \frac{2.25}{0.354} = 6.3 \text{ in. per hour}$$

and,

$$\alpha = 0.70\ \frac{1}{1 + 0.013\,\sqrt{0.25}} + 0.30\ \frac{1}{1 + 1.3\,\sqrt{0.25}} = 0.88$$

$$q = \frac{375 \times 0.88 \times 3}{0.25^{\frac{3}{4}}} = 2\,830 \text{ sec-ft. per sq. mile}$$

and,

$$Q_{\text{max.}} = 0.0313 \times 2\,830 = 89 \text{ sec-ft.}$$

Ralph W. Powell,[45] M. Am. Soc. C. E. (by letter).—This paper has been quite fully discussed and the writer wishes to touch on only a few points. The authors derive a formula for C, the run-off coefficient. It would seem that if z is the rate of absorption plus evaporation, in cubic feet per second per acre, the total number of cubic feet per second being absorbed and evaporated would be zA, the net run-off would be $iA - miA - zA$, and C would be $1 - m - \frac{z}{i}$, instead of as in Equation (39). The authors seem to have allowed for no absorption or evaporation from the stored portion of the precipitation.

The storage here referred to is that "falling in depressions, cavities, etc.," and evidently is not meant to include "channel storage." The writer questions whether Kutter's formula, or any other formula derived from experiments on steady flow, applies to this case. It would seem that the channel must act to some extent like a retarding basin and make the time of concentration for the uniform rainfall assumed by the authors, somewhat more than that given by their method. If this is true the error, of course, would be on the side of safety.

Actual storms are not like the one assumed, however, and they do not occur simultaneously over the water-shed. There is the extreme possibility of a storm moving down a valley at the same velocity as the flood crest. This would mean that the maximum effects of the most intense rainfall in each part of the drainage area would reach the mouth simultaneously and that the maximum flow would be $Q = CiA$, in which, i would be the intensity for a very short time, t, approaching zero as the timing of the maximum rainfall at each point in the area approached the ideal just stated. This would mean values of i of the order of 10 in. per hour. It would seem, therefore, that peak run-off resulting from any given storm depends too vitally upon the velocity (including direction) of the storm across the drainage area to make worth while any refinements of methods which neglect it.

Speaking of small values of t it must be remembered that Equation (2) and all the information compiled[46] by Merrill M. Bernard, M. Am. Soc. C. E., apply only to times greater than 2 hours. For shorter times, the formula must be changed to,

---

[45] Asst. Prof. of Mechanics, Ohio State Univ., Columbus, Ohio.

[46] See pp. 618–622.

$$i = \frac{k}{(t + b)^e} \qquad \text{(113)}$$

in which, b is about 7 or 8 min.[47]

On the other hand, when the area becomes large another correction is necessary as pointed out by the authors. From the study of a small part of the data given in the Appendix of Part V of the Technical Reports of the Miami Conservancy District, the writer has derived a rough empirical correction factor of the form, $(1 - 0.015 \sqrt[3]{A_m})$, in which, A_m is the area, in squares miles. This gives values nearly the same as those in Table 15, but was derived independently. It is evident that this correction should be made whenever A_m is more than, say, 100 sq. miles.

Merrill M. Bernard,[48] M. Am. Soc. C. E. (by letter).—The authors' paper may be accepted as a definite step toward the goal of determinate run-off values. With it they have provided new tools with which to attack the problem of rainfall-run-off relationships.

The limitations of the rational theory must first be accepted and its field of application defined before it can become the basis of intelligent design. A principal drawback is, that the magnitude and frequency of a storm—the run-off from which brings with it the run-off of previous storms, detained in storage as snow and ice—cannot in any way become the measure of the magnitude and frequency of the resulting flood flow. The writer, therefore, would limit the application of his suggestions in the following discussion to that part of the Eastern United States south of the snow line, and to summer conditions only, for the northern section.

Too little emphasis has been laid on the frequency with which flood magnitude and duration may be expected. This factor becomes the measure of efficiency of any structure, the purpose of which is to remove or pass flood waters. Drainage structures may be divided into two general classes: First, conduits or channels, for the removal of storm run-off; and, second, spillways and important bridge openings.

In economical design the first class demands a balance between cost and capitalized damage resulting from prolonged inundation, the damage being understood to include that to private property, hazard to health, and curtailed convenience to the public.

In addition to property damage the structures of the second class involve hazard to life. In that case design must provide capacity to meet a maximum condition or, in terms of frequency, flood intensities reached or exceeded once in from 100 to 200 years. Design, based on an isolated storm intensity which is classed as "maximum" in a short-term rainfall record, could be dispensed with in favor of direct application of personal judgment to the size of the structure itself.

[47] "Frequency and Intensity of Excessive Rainfalls at Boston, Massachusetts," by Charles W. Sherman, M. Am. Soc. C. E., *Transactions*, Am. Soc. C. E., Vol. 95 (1931), p. 954, and the discussion by M. F. Wagnitz, M. Am. Soc. C. E., and L. C. Wilcoxen, Assoc. M. Am. Soc. C. E., p. 964.

[48] Cons. Civ. Engr., Crowley, La.

It is obvious that the frequency of the storm is not necessarily the frequency of the flood produced by it. A highly intense storm of long duration, to be expected not oftener than once in 25 years, may occur at a time following a period of little or no rainfall. Then, especially on open, pervious watersheds, the demands of the losses to run-off are high, resulting in a low value of the coefficient, C, and a unit run-off that, were flow records available over a sufficiently long period, might be found to have a frequency of once in 5 years. Flood frequency will approach storm frequency, however, because the outstanding storms of record have produced flood flows which must be nearly as infrequent in occurrence.

Failure to advance in this natural science cannot be laid altogether to blind faith in the old and accepted empirical formulas, but in the fact, as the authors have stated, that there has been no uniformity in the conception of assumptions made in the present use of the rational method. Confusion in an understanding of its application to rural areas and stream-flow analysis has arisen where the terms in the equation, $Q = C\,i\,A$, have been given meanings applicable only in the field of storm sewer design, or where the terms have been inadequately or obscurely defined.

Particularly does there seem to be no uniformity in the understanding of the run-off coefficient, C. It is usually defined as the ratio of the rate of run-off to that of rainfall, which may take any of the following meanings:

(*a*) Total run-off to total rainfall for the entire storm period.
(*b*) Maximum rate of run-off to maximum rate of rainfall.
(*c*) Rate of run-off at time of concentration to average rate of rainfall at time of concentration.
(*d*) Maximum rate of run-off to average rate of rainfall throughout a duration period equal to time of concentration.

The rational theory assumes that the rate of travel of the flood crest is the same as that of a particle of water leaving the remote (in terms of time), portion of the water-shed. This assumption may be met in the city storm sewer system, but on the large, agricultural water-shed, it must be modified to recognize a lag between time of concentration, as established by the authors' run-off equation, or by estimated velocities and the arrival of the flood crest. The hydrologist has no interest in the rate of run-off prevailing at the end of the calculated concentration period, but in a maximum rate that will occur later. The writer believes, also, that to burden an already laborious procedure with the complications of non-uniform flow, involved in the travel of the flood crest, is out of the question. Since designers are interested only in maximum discharge and, since it is practicable to determine a concentration period, from determinate factors, representing time in transit from headwaters to concentration point, the coefficient, C, should be understood to be the ratio of maximum discharge to the average rate of rainfall intensity throughout a duration period equal to such time of concentration.

Concentration time should be understood to be a time interval, at the end of which all effective parts of the water-shed are contributing to the flow at the point of concentration. It should be conceived as a time contour, developing around the point of concentration, and progressively receding to the limits of the water-shed. This will exclude artificial reservoirs and appreciable areas of swamp, lake, or marsh, in which the run-off waters because of restricted outlet or other cause, will not reach the point under consideration until the condition of maximum flow has been reached and has passed.

While the theory is stated as a simple basic relationship, $Q = C\,i\,A$, the method of application and the procedure change continuously as the area embraced increases. Conceive of a water-shed, the outfall channel of which heads as a city storm sewer system, discharging into a local stream which, after receiving the drainage waters from an agricultural area, empties into a river which, in turn, becomes the tributary to a still larger stream. Three distinct problems are met involving cases in which run-off is produced: First, by short intense local showers; second, by a single widespread storm or a combination of such storms occurring nearly at the same time; and, third, by the melting of the winter's snow or protracted wet spells, or by their coincident occurrence, over large river basins. In each case the factors affecting the ratio of run-off to rainfall rate, except for a common name and symbol, are different in character and in the degree to which they influence that ratio.

An intense downpour of 200 min. or less, critical to the storm sewer system, becomes only one of several phases of a storm period producing run-off from the larger areas. The average rainfall intensity prevailing throughout the storm phase may not be far less than its maximum in value, while the average of an extended storm period will not approach the storm maximum; and as duration continues it will vary between much narrower limits. It is significant that the expression for rainfall intensity changes rather abruptly at the end of one or two hours. The equation,

$$i = \frac{a}{t + b} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots(114)$$

may be taken as representing the comparatively short period of continuous downpour; and the equation,

$$i = \frac{K}{t^e} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots(115)$$

for the longer durations, representing the average of intermittent rainfall throughout the storm period.

Another difference lies in the fact that individual storms may arrange themselves in many ways, peaking in the early stages, in the middle, or at the end of the storm period. An intensity curve group will give the relation between rainfall intensity, duration, and frequency for a locality, but it cannot account for the variation in average intensity at intervals throughout the individual storm.

Fig. 12 shows nine storm curves[49] plotted over the rainfall intensity curve group[50] for Central Illinois. While there is no apparent order in their early stages, they straighten out, after about 400 min., and in general follow the law of the curve group. The shape of the storm curve, materially affecting velocities, then concentration time, and, finally, the selection of the controlling rainfall intensity, is of relatively high importance to the storm sewer system, when concentration periods are short, but it reduces in importance for large areas having concentration time of many hours.

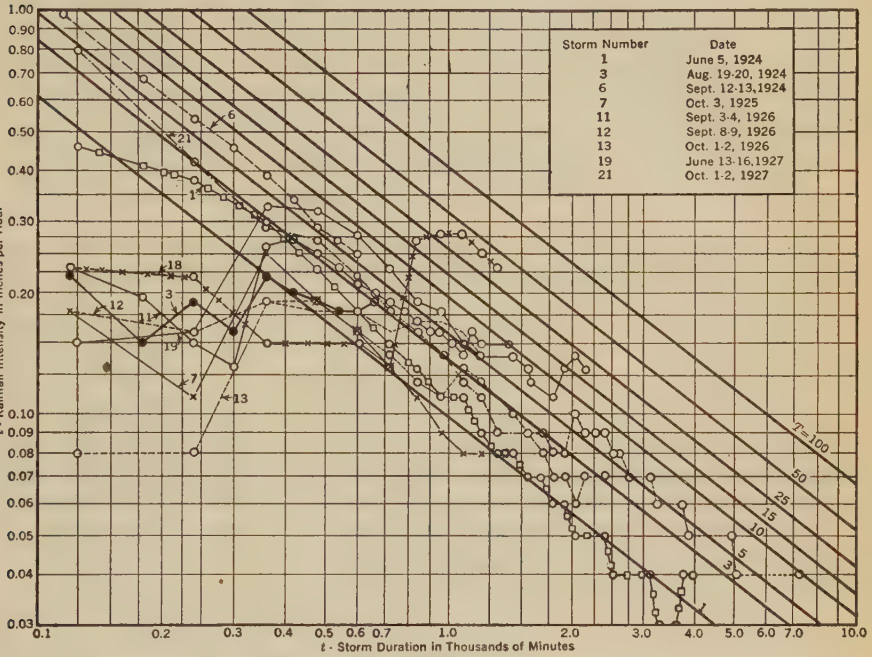

FIG. 12.—COMPARISON OF STORM CURVES WITH RAINFALL INTENSITY CURVE, GROUP FOR CENTRAL ILLINOIS $\left(i = \frac{23\,T^{0.8}}{t^{0.78}}\right)$.

There seems to the writer no justification in extending the use of the rational method, in its present state of development, to flood-flow problems covering several thousand square miles. The treatment of such cases requires a rainfall intensity distribution factor, as yet not fully developed, and the factors affected by topography and soil conditions must become carefully weighted averages. Furthermore, it is probable that the coefficient, *C*, will take an entirely new range of values.

The authors' paper, with the writer's rainfall intensity study covering the Eastern United States,[51] and data, recently gathered in detail for Central

[49] "Run-Off Investigations in Central Illinois," U. S. Bureau of Public Roads, and *Bulletin 232*, Univ. of Illinois Eng. Experiment Station, 1931.

[50] See p. 617 *et seq.*

[51] See p. 592, and subsequent discussions.

Illinois,[49] presents an opportunity to develop a complete example of the application of the rational theory to agricultural drainage and stream-flow problems.

For the Eastern United States and for duration periods greater than 1 hour, the general formula for Q (Equation (24)), may be expressed as:

$$Q = U\ (C\ A\ K)^{4g}\ T^{4xg} \ldots\ldots\ldots\ldots\ldots\ldots (116)$$

in which K, T, and x are the intensity coefficient, frequency coefficient, and frequency exponent, respectively, taken from the writer's charts, all other notations being the same as in the authors' paper. The symbol, U, becomes a factor reflecting water-shed characteristics, in which, e is the exponent of duration, t, thus,

$$U = \left(\frac{60\ P}{L}\right)^{4eg} F^{8eg}\ \frac{S^{1.5eg}}{1\ 000^{2eg}} \ldots\ldots\ldots\ldots\ldots\ldots (117)$$

The formula may be reduced by using the average value of e for the Eastern United States, which varies from 0.75 to 0.83, as 0.80. Then,

$$Q = U\ (C\ A\ K)^{1.25}\ T^{1.25x} \ldots\ldots\ldots\ldots\ldots\ldots (118)$$

and,

$$U = 1.897\ (B\ F)^2\ S^{0.375} \ldots\ldots\ldots\ldots\ldots\ldots (119)$$

In this form, Equation (119) lends itself readily to the inclusion of other factors (such as one for rainfall intensity distribution) and permits the rapid comparison of Q for various frequencies, which is a decided advantage to design. It will be found that the Illinois data have provided values for all factors in the formula, as shown in Table 16.

The rainfall intensity formula for this locality is,

$$i = \frac{23\ T^{0.30}}{t^{0.79}} \ldots\ldots\ldots\ldots\ldots\ldots (120)$$

and the run-off equation is,

$$Q = U\ (C\ A\ K)^{1.246}\ T^{0.374} \ldots\ldots\ldots\ldots\ldots\ldots (121)$$

in which,

$$U = \left(\frac{60\ P}{L}\right)^{0.934} F^{1.969}\ \frac{S^{0.369}}{29.9} \ldots\ldots\ldots\ldots\ldots\ldots (122)$$

Transposing,

$$C_a = \left(\frac{Q}{U\ (A\ K)^{1.246}\ \ T^{0.374}}\right)^{0.802} \ldots\ldots\ldots\ldots\ldots\ldots (123)$$

It will be found that, as long as T and i are in accord with the law of the curve group, the time of concentration will remain constant. The values in Columns (5), (6), (7), (8), (9), (12), (13), (14), (15), and (16), in Table 17, were obtained by the following procedure:

First.—A value of the drainage coefficient for $T = 1$ year was calculated by Equation (123);

Second.—The 1-year i was obtained by dividing the unit, q, taken from the storm record, by the 1-year C;

Third.—Concentration time was established by taking the 1-year i into the curve group to an intersection with the 1-year frequency curve;

Fourth.—The average rainfall intensity for the duration equal to concentration time, as determined by the first, second, and third steps, was taken from the individual storm curve;

Fifth.—This intensity, taken into the curve group with its time of duration, established its frequency; and,

Sixth.—The unit, q, was divided by the prevailing i to arrive at the actual value of the drainage coefficient, shown as C_a in Columns (9) and (16), Table 17, for each storm and water-shed.

Comparative results, using two values of the factor, P, are given in Table 17, the former, with P_1, assuming rainfall intensities as uniformly distributed, and the latter, with P_2, assuming rainfall intensities as following the curve of the type, $i = \frac{K}{t^{0.5}}$.

It would appear to the writer that opportunity for a condition to occur in accordance with the use of P_2, that is, a storm that comes to a peak in

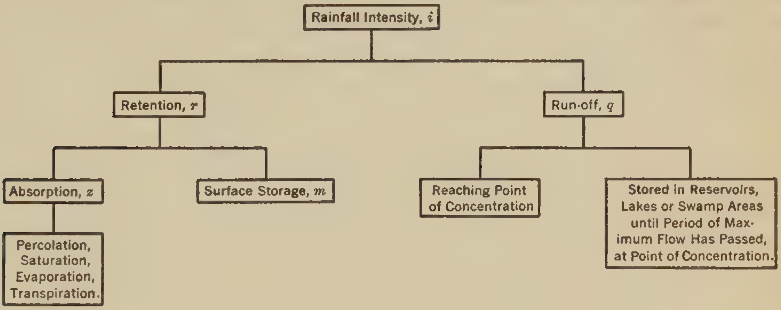
the first 20 to 60 min. of its duration and progressing down stream (thus shortening concentration time by building up high unit discharges and velocities at the head-waters), will be much more infrequent than an average condition, represented by P_1, the assumption of a uniform intensity over the water-shed above the point of concentration. Table 17 compares the effect of P_1 and P_2 on the other factors affecting run-off.

The rainfall intensity, i, the rate at which water is applied to an area as rain, is distributed as shown in Fig. 13.

The run-off, Q, is divided into that portion which will reach the point of concentration in time to contribute to maximum flow and that which is delayed, as storage in lakes, swamps, or reservoirs, until after the condition of maximum flow is past. The latter becomes a direct deduction from effective area.



Rainfall Intensity, i
Retention, r
Run-off, q
Absorption, z
Surface Storage, m
Reaching Point of Concentration
Stored in Reservoirs, Lakes or Swamp Areas until Period of Maximum Flow Has Passed, at Point of Concentration.
Percolation, Saturation, Evaporation, Transpiration.

FIG. 13.

The retention, r, is a factor embracing all other losses to run-off. It is made up of a factor, z, called absorption, and a retardation factor, m, which might be referred to as surface storage.

The factor, z, is a function of atmospheric conditions and rainfall intensities throughout the critical period of the storm and of the amount and rate of rainfall immediately preceding. It also reflects the capacity of the soil to pass water to underground storage, as percolation, or to retain it as absorption. The formula,

$$i = q + r \quad \text{(124)}$$

is a straight-line relationship in which slope, and, therefore, the value of C, is unity. This is demonstrated by plotting i with q, and projecting the points with slope = 1, to the i-axis, where the intercepts will become the values for r.

If a point group is enveloped by a curve having a slope, M, and the points are projected with that slope to the i-axis, the intercepts, z, measuring absorption, will result; thus,

$$i = Mq + z \quad \text{(125)}$$

$$q = \frac{1}{M}(i - z) \quad \text{(126)}$$

and,

$$C = \frac{q}{i} = \frac{1}{M}\left(1 - \frac{z}{i}\right) \qquad (127)$$

The factor, $\frac{1}{M}$, or $C_{\text{max.}}$, becomes constant for, and the maximum drainage coefficient on any water-shed is established by, its topography, type of soil, vegetable cover, and degree of development. This factor, modified by the combined effects of i and z, becomes the coefficient, C, for a particular storm.

The retardation factor, m, herein classified as surface storage, is represented by the difference between unity and $C_{\text{max.}}$ for any water-shed. It is a function of topography, shape, and development of the water-shed and is the factor, acting through surface storage as an equalizing influence, which establishes the rate at which the various parts of the water-shed will contribute to maximum flow; thus,

$$i = q + r = Mq + z \qquad (128)$$

$$q = i - r = \frac{i - z}{M} \qquad (129)$$

$$i\left(1 - \frac{1}{M}\right) = r - \frac{z}{M} \qquad (130)$$

and,

$$1 - \frac{1}{M} = \frac{r}{i} - \frac{z}{Mi} \qquad (131)$$

That m (or $1 - \frac{1}{M}$, or the ability of a water-shed to delay the delivery of run-off water to the point of concentration), is a function of the slope, M, and not a deduction factor, as z, is illustrated in the rainfall and run-off studies,[52] by Ivan E. Houk, M. Am. Soc. C. E. Bare soil, relatively incapable of retarding run-off is shown to have slope, M, very little different from 1, or to have a low value of $1 - \frac{1}{M}$, while the plots in which the soil was spaded and raked, representing a surface condition conducive to storage, showed a correspondingly high value of m.

Where water-sheds are closely grouped and where conditions are similar, a composite point group may be enveloped by a curve that will apply to the individual water-sheds, as shown in Figs. 14 and 15.

Using values of P_1,

$$C_b = 0.284\left(1 - \frac{z}{i}\right) \qquad (132)$$

and with P_2,

$$C_b = 0.287\left(1 - \frac{z}{i}\right) \qquad (133)$$

Values for C_b, for Central Illinois, are listed in Columns (11) and (18) of Table 17.

---

[52] Technical Reports, Miami Conservancy Dist., Pt. VIII, Fig. 24, p. 124.

Comparison is made with the rainfall-run-off studies[53] of C. E. Ramser, M. Am. Soc. C. E., in Western Tennessee. Values of $C_{\text{max.}}$ for the individual water-sheds are compared with the composite value in Fig. 15.

Rainfall-run-off measurements made by the writer at Crowley, La., are shown in Table 18. The resulting value of $C_{\text{max.}}$ is 0.52. These water-sheds, all uniformly flat, are almost identical as to soil type, which is a dense, impervious clay.

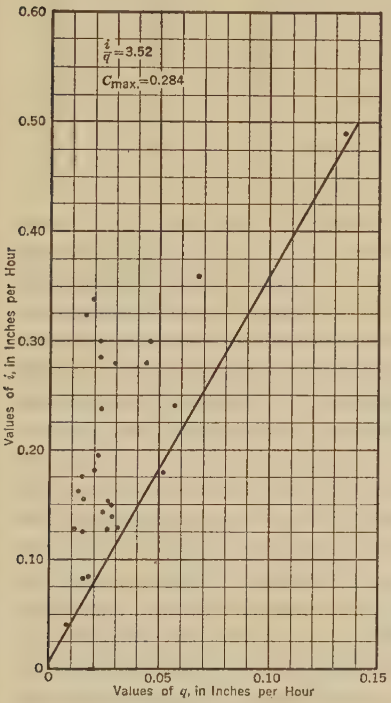


FIG. 14.

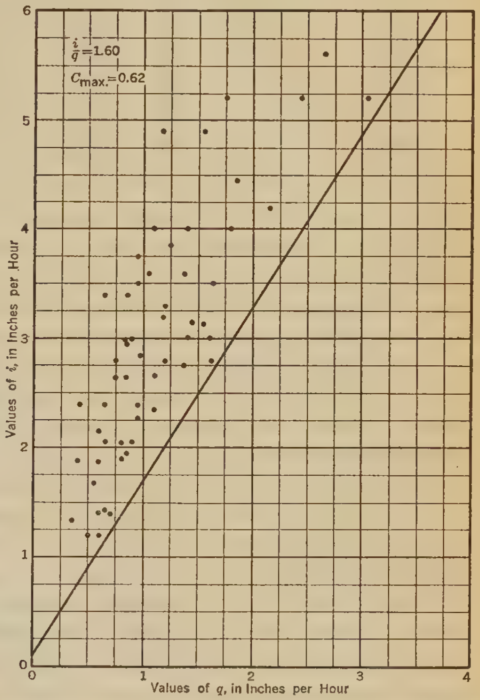

FIG. 15.

From recorded data presented in this discussion, values have been given to all factors affecting run-off, from eight storms over ten water-sheds. It has been shown that, from data made available by any reasonably accurate topographic survey (except the direct measurement of Kutter's n to be found in the Illinois data, which would ordinarily be assumed), all factors except z and $C_{\text{max.}}$ may be given determinate values. The writer has expressed Q in terms of storm frequency, but not flood frequency, and to that extent has fallen short of the goal of direct flood-flow determination.

The tendency in design will be to use $C_{\text{max.}}$ as the drainage coefficient, considering the margin between it and the values actually developed as a factor of safety. This suggests an analogy between the design of hydraulic structures to remove storm run-off and the design of structural members, in that $C_{\text{max.}}$

---

[53] "Run-Off from Small Agricultural Areas," *Journal of Agricultural Research*, Vol. 34, No. 9, p. 799.

may be compared to the ultimate strength of a beam, the former being fixed by features of topography, soil, and cover of the water-shed, and the latter by its material, shape, and size. The actual C, resulting from any storm, may be compared to the working stresses developed in the beam, both occurring in any magnitude and with any frequency. The ratio of ultimate strength to working stress is taken as a factor of safety, as may the ratio of $C_{\text{max.}}$ to the actual C. Here the analogy ends, however, for the entire structure may depend upon the beam, while in the case of the drainage conduit or channel only nominal damage will result from overstressing its capacity.

TABLE 18.—RAINFALL-RUN-OFF MEASUREMENTS, AT CROWLEY, LA.

It is not within the scope of this discussion to go into the problem further, except to suggest a possible approach to each of the factors remaining indeterminate.

The occurrence of a low value of z with a high value of i must be regarded as a purely fortuitous phenomenon, with the chances to combine being the product of their respective frequencies. If a flood-flow frequency of once in 5 years, using T_i and T_z equal to 5, is the design criterion, then the designer is, in reality, providing capacity, the chances to be reached or exceeded being once in 25 years. The factor, z, as in the case of i, can be expected to reduce as rainfall duration increases. It can also be expected to reduce as storm magnitude and duration, in terms of T_i, increase. If z and i, in terms of T_i and T_z, are combined in Equation (127) as $\sqrt{T_i}$ and $\sqrt{T_z}$, the resulting value of C, by reducing the needlessly large safety factor involved in the use of $C_{\text{max.}}$, will produce a more balanced ratio between efficiency and economy in design and will give values of Q having an approximate flood frequency, T_f. At least, the design will have taken cognizance of the fact that the extreme values of i and z combine infrequently.

It is reasonable to expect low values of z during or immediately following an extended wet spell, disregarding, of course, winter storms on frozen watersheds. What constitutes (in terms of frequency, intensity, and duration) a storm period to produce maximum saturation is not known, but an approach to it may lie in the fact that the expression for rainfall intensity, for the Eastern United States, $i = \frac{K\,T^x}{t^e}$, may be extended to duration periods of thirty days.[54]

---

[54] See pp. 620–621, Table 7.

Apparently, the range in the value of $C_{\max.}$, for topographic and soil conditions to be found on the ordinary agricultural water-shed, is from 0.28 to 0.65. Tentative deductions from unity, C, to be added as the influences of topography, soil, and cover combine—and given as a guide to values of $C_{\max.}$ for agricultural water-sheds—are, as follows:

Topography.—	
Flat land, with average slopes of 1 ft. to 3 ft. per mile	0.30
Rolling land, with average slopes of 15 to 20 ft. per mile	0.20
Hilly land, with average slopes of 150 to 250 ft. per mile	0.10
Soil.—	
Tight, impervious clay	0.10
Medium combinations of clay and loam	0.20
Open, sandy loam	0.40
Cover.—	
Cultivated lands	0.10
Woodland	0.20

CHARLES H. LEE,[55] M. AM. SOC. C. E. (by letter).—This paper represents a thorough attempt to analyze the rational method of estimating flood discharge, particularly as applied to unimproved drainage areas. The rational method was originally introduced as an improvement in estimating maximum storm run-off from small urban and suburban areas. As has been stated by the authors and pointed out by the writer,[56] it is also applicable to drainage areas of natural streams, where it has practical application in the design of waterway areas for stream-bed structures, such as culverts, bridges, spillways, overflow dams, etc. The authors have made a real contribution to the subject in their searching and logical analysis of the "detail method" of application. They have also presented some very suggestive material in Part II, but it is open to question whether as yet it is a step in advance to attempt to apply the rational method as a formula. The element of judgment is still present both in the application of the method as well as in the choice of basic values for a given drainage area. Under such conditions no formula can be devised that would be "fool proof." It is not believed that such a formula would be much of an improvement over the use of empirical formulas.

There is an important difference in the application of the rational method to the design of storm sewers or long storm drains and to stream-bed structures. To construct the former of a capacity sufficiently large to carry the maximum possible storm discharge would ordinarily be prohibitive in cost, and it is customary to design for maximum storms likely to occur once in an assumed period of years. In the case of bridges, culverts, spillways, etc., the relative cost of the waterway area is small compared to the cost of the entire structure, and it is usually economic to provide for the absolute maximum flood discharge. This fact suggests the importance of thorough consideration of factors other than rainfall intensity, which may contribute to the occurrence of a maximum when applying the rational method to unimproved drainage areas. The mention of a few instances may be in order as a part of the discussion of the authors' paper.

[56] *Transactions*, Am. Soc. C. E., Vol. 93 (1929), p. 433.

For small drainage areas in arid or semi-arid regions subject to local storms of great intensity known as cloudbursts, special consideration should be given to the value of C. Soils behave quite differently in their ability to absorb surface water, depending on their initial condition of moisture. This condition may be: (*a*) At saturation with complete filling of all voids; (*b*) at field capacity with partial filling of voids after all gravitational water has drained out; (*c*) at the point (wilting coefficient) where all moisture has been removed so that vegetation wilts; or (*d*) with all except hygroscopic moisture removed. In a dry arid region during the hot summer months the quantity of hygroscopic moisture is small and there may be a high degree of desiccation of the soil to considerable depth.

For moisture conditions between field capacity and saturation and with good drainage, rainfall upon the surface is readily absorbed and passes downward through the soil column. For moisture content less than field capacity the soil retains added moisture until that capacity is reached, and progressive downward penetration occurs only as field capacity is exceeded in the soil column above. For highly desiccated soils this retarding action becomes a positive resistance to wetting, illustrated by the action of single raindrops falling upon a dusty road, or the addition of moisture to dry peat. A rainfall of great intensity, falling upon the surface of an extremely dry soil column, may thus encounter an actual resistance to absorption, producing immediate saturation at the surface and run-off, with dry soil below.

In addition to this surface tension phenomenon, there may also be resistance to penetration produced by trapped air in the soil. As the solid water represented by field capacity varies roughly from ½ in. to 1 in. per ft. of sandy to silty loam soil, it is obvious that a highly desiccated soil column of several feet might maintain this condition for the duration of the storm, with a value of C of nearly 1.00. On the other hand, if initially at field capacity, the same column would immediately commence the downward transmission of water absorbed at the surface with a value of C nearer 0.50. These considerations are especially important in a cloudburst country, such as that traversed by several of the transcontinental railways, and the long water supply conduits common in the West. The writer has also noted their importance in the coast region of Central California, where early fall rains following an excessively dry season have produced higher rates of flood run-off into storm sewers from small unimproved areas than storms of equal intensity occurring during the winter.

Among other conditions that may produce maximum flood flows exceeding those estimated by a routine application of the rational method may be mentioned frozen ground, warm rain falling upon snow, the effect of fire in destroying the vegetation mat, and the natural flow in the stream from a preceding storm at the beginning of a storm of maximum rainfall intensity. The authors considered the condition of saturation of the surface from an immediately preceding storm, but did not mention the possibility of there being appreciable flow already in the stream. The theoretical absolute maximum resulting from the latter condition is double the value computed, assuming that a second storm of equal intensity and duration followed immediately after the storm for which the computations were made. An actual instance for which the data were analyzed by the writer indicated a discharge from a small drainage area 80% greater for a second storm immediately following an earlier one of about the same intensity.[57]

These instances illustrate the importance of a broad consideration of all factors that may enter the problem where the rational method is being applied to estimate maximum flood flow as a basis for designing stream-bed structures.

R. L. GREGORY,[58] and C. E. ARNOLD,[59] ASSOCIATE MEMBERS, AM. SOC. C. E. (by letter).—Briefly, the tenor of the discussions may be summarized in four general observations, which follow:

(1) No errors in conceptions, conclusions, statements, suggestions, or analyses were proved to exist in the paper.

(2) All discussers agree that the proposed run-off formulas are rational and logical in derivation.

(3) While there is some disagreement as to the degree of usefulness of the proposed formulas, many of the discussions display a keen appreciation not only of the value of the formulas, but also of the paper as a whole.

(4) A few of the discussers profess to favor either methods of their own, or existing formulas and systems, in all cases; while others would use the proposed formulas, or a more detailed process, according to the requirements of the problem in question.

Any one, in reading the paper, should form the definite conclusion that the subject-matter therein was presented without fear, favor, or undue feeling. Severe criticisms and analyses of existing data and methods were made in the full anticipation of vigorous counter-attacks from many engineers, who had previously advanced, or openly approved, conceptions, or formulas, which the contents of the paper prove to be erroneous or inadequate.

It is, however, not surprising that analysis was not resorted to by these individuals, such generalities as, "the writer prefers," or, "in the writer's opinion," or, a brief preface to a more or less lengthy résumé of former writings, being used instead. Generalities are insufficient when dealing with fundamentals of an involved subject. The foregoing observations, (1) and (2), still hold.

On the other hand, some excellent discussions came from engineers, who, in addition to making an honest effort to understand the subject as presented, were possessed of sufficient magnanimity of spirit, sense of duty, energy, and courage, to point out (in a work, for which others were responsible) many parts of the paper, which to them seemed most pertinent and worthy of study and use. The profession owes its advancement to these individuals, and others of their kind, who, not content to confine their efforts to their own contributions, unselfishly encourage and further the development of constructive thought and methods regardless of source, making thereby fruitful use of their talents, and fulfilling the inevitable responsibilities which accompany such gifts.

[57] *Transactions*, Am. Soc. C. E., Vol. 93 (1929), p. 439.

[58] Chf. Insp., Los Angeles County Storm Drain Div., Los Angeles, Calif.

[59] Los Angeles, Calif.

Many and varied conflicting statements and opinions are contained in the group of discussions—some are diametrically opposed, the one to the other; some are not pertinent to the subject; others convey a lack of proper conception, with a consequent tendency to mislead; while still others are conducive to a better understanding.

After a careful reading of the discussions in conjunction with a review of their paper, the writers, in contemplating the probable state of mind of the reader who has had the fortitude to attempt a digestion of all the material submitted, can visualize a distinct tendency toward confusion. They realize that time and space will not permit discussion of all issues raised, but shall endeavor, subsequently, to cover only the more important points, and to submit material which, it is believed, will be helpful.

There is an expressed (or intimated) belief in more than one discussion that the writers intended, in their paper: (*a*) To disestablish the rational method; and (or) (*b*), to establish formulas which could cover all phases of an involved problem at one stroke and be used by the designer without any qualifications or limitations. Neither intention was, or is, possessed by the writers; nor does the paper, in any part thereof, if read thoroughly, convey the thoughts.

The writers did, painstakingly, attempt the analysis of the rational method, as practiced by many; and pointed out in no uncertain terms certain limitations, fallacious assumptions, and errors thereof, some of which were commented on and thoroughly appreciated by Mr. Reeves, and others, as shown in their discussions.

The run-off formulas, presented by the writers as a logical sequence of their analyses, rest upon the solid foundation of Equation (1). This equation is axiomatic—irrefutable—and does not belong solely to the rational method, as practiced. All run-off formulas and methods, if logical, must embody its principles. Any one of the three factors, C, i, and A, is subject to an infinite number of variations. The writers were not unmindful of these possible variations (see "Introduction," "Use of Rainfall Curve," "Conclusions" (1) to (4), inclusive, "Statement," and "Factor C, the Run-Off Coefficient," in Part I). So many re-statements of the writers' preliminary remarks (or corollaries thereof), regarding the possible variations of storms, occur in some of the discussions, that one may easily be led to believe that the writers really think that all rains follow the precise assumptions set up in the rational method.

All agree that a storm may, or may not, cover the entire water-shed throughout the time of concentration thereof; that its rates of precipitation may be more intense on one part of the area than on another; that its vortex may travel in any direction, up, down, or across; and that rainfall may even be discontinuous, or intermittent, during any time interval. In the face of so many possible variations, some assumption must be made by any one when attempting to solve a run-off problem, and, by all means, the most logical and useful assumption should be made when evolving a formula. The writers were not secretive about their choice (see sub-headings, "Use of Rainfall Curve," and "Statement" under main heading, "The Rational Method," in Part I). Observe, also, that certain limitations of the rational method are recorded (see "Remarks," under the heading, "Suggestions for Use of Formulas," in Part II). That the formulas were developed logically was admitted by practically all the discussers and may be verified by a study of the paper.

While the intensity-time-frequency curves for use with the method (see "Rainfall Curves," "Use of Rainfall Curve," and "Statement," in Part I) likewise carry inherent limitations (that is, due to construction, they set up a probable average rate of precipitation for any given time interval), they do furnish the only feasible basis yet devised for forecasting frequency periods of the average storm and correlating the time of concentration of a given water-shed (or part thereof) with an expected intensity.

Some engineers prefer to divide the water-shed into time zones for the purpose of applying varying intensities to the different sub-areas thus formed. For this purpose the special assumptions (in regard to intensities) of the rational method can be utilized as a forerunner. The proposed run-off formulas are especially adapted, since approximate times of concentration for the water-shed (or any sub-water-shed) may be found quickly through their use. For approximate purposes the solution for a water-shed may be made in one operation, if a weighted value of R_H (weighted by the sub-areas in much the same manner as outlined under the heading, "Special Case," in Part II), is obtained for use in the formulas. In the light of present information, however, the necessity for, or desirability of, so dividing the area is questionable (see "Statement," under "The Rational Method," in Part I).

It should be emphasized, however, that the use of the formulas is not limited to the strict assumption of uniformity for the intensity, but requires the consideration of an average value for it. The use of Table 3 constitutes a limit to uniformity, only in so far as the values of the factor, P, influence times of concentration.

A study of the paper should make it evident that the writers, instead of trying to disestablish the rational method, have not only presented analysis, which should help to clarify many assumptions and practices, but have contributed to its advancement into further fields of usefulness.

The run-off formulas are capable of being used with any type of rainfall curve (or group of curves), regardless of shape or frequency period (see headings, "Special Reduction of Equation (24)," and "Remarks Concerning Examples 6, 7, 8, and 9," in Part II; and refer, by all means, to "General Solution by Equation (29)," presented subsequently in this discussion). That the formulas may be logically applied to any size or type of water-shed (whether or not it happens to be a part of another area, and regardless of the shape and condition of the main channel of flow) follows naturally from their derivation. Furthermore, it should be observed that the proposed run-off formulas, are the only ones in existence, which afford: (1) A means of arriving readily and reasonably at the time of concentration of an area (or any sub-water-shed thereof), enabling, thereby, the ascertainment of the probable average intensity for any frequency period, which when necessary may be studied in turn in more detail as to distribution or effect; and (2), facilities for consideration of all factors resulting from definite assumptions.

Although their evolution is somewhat formidable, the formulas are complicated only in derivation (see "Suggestions for Use of Formulas, Method No. 2," in Part II, and the splendid discussions by Messrs. Longacre, Kemmerer, and others).

A statement, which contains a depth of meaning and is well worth repeating, was made in the excellent discussion by Mr. Arledge, as follows: "The future worth of the formulas will depend largely on the amount of intelligent use to which they are subjected." When and how to use them must be determined, to a great extent, by the ingenuity of the engineer in solving the individual problem confronting him. Their capabilities of use will increase as more extensive experimentation by the profession makes available more accurate data for selection.

It is easier, of course, to solve such formulas as, $Q = C_F \sqrt{A}\, R$; $Q = C_1 M^{\frac{3}{4}}$; $Q = 210\, M^{\frac{2}{3}}$; or, $Q = 10\,000 \times 80\% \sqrt{A}$, which were presented in the discussions by Messrs. Sherman, Ryves, Hickox, and Jarvis, respectively.

These and other similar equations have little in common with the formulas and methods proposed by the writers; direct comparisons therewith can not be made. In such formulas the run-off is approximated through a multiplication of the area (raised to some exponent) by a coefficient. Necessarily, many variables are covered by a single constant, even if the use of one of the equations be confined to a single locality. Such formulas approach closely, indeed, Equation (1), with which the writers began. The question naturally arises, why not use Equation (1) as a basis for approximations through comparisons? Why complicate it by an exponent which must change in value and meaning for the many unseen variations in missing factors?

It is true that much good information on flood flows of streams has been collected by engineers. The writers do not wish to detract from its value by any statement or act. Such collections should continue to be made and studied in the future. Hydrographs, high water marks, and other data should be obtained where possible. When a complete hydrograph, which conforms to the flood to be provided for, is available, the problem is solved—no run-off formula is needed. Seldom, if ever, is this condition found to exist in recognizable form.. Proper records of precipitation for large floods are almost always lacking, and, for the smaller flows, sufficient data are seldom available. If hydrographs, together with corresponding information on precipitation, are available, there still arises the difficulty of ascertaining the flow for storms other than those which produced the recorded discharge.

The development of intensity-time-frequency curves is due, directly, to the need of other means than direct measurements, to assist in solving the run-off problem. These curves, however, could be of no avail without means of ascertaining, and correlating with their proper time intervals, times of concentration of water-sheds. Equation (1), alone, or with the area raised to an exponent, could not be of any use in making determinations of times of concentration without resorting to hypothetical reasoning.

The fundamentals of the hypotheses, on which the writers' formulas are based, are not altered by a change in the size of the channel of flow. Such arbitrary limits, as "500 sq. miles," or "artificial channels," may be recognized as applicable only when there exists a lack of proper conceptions, or ingenuity, on the part of the engineer, or inadequate available data, or combinations thereof.

The formulas, however, are not recommended to be used without the exercise of judgment. It may be necessary in some cases to alter times of concentration and resulting intensities, due to the effects of certain "restrictions and pondage." Judgment will always be needed with any method, system, or formula, but no *bona fide* assistance in the solution of the problem should be rejected.

Specific Remarks.—After rendering various opinions concerning the proposed formulas and giving a rather lengthy discourse on soil characteristics in relation to the run-off coefficient, Mr. Lee makes a number of inaccurate and misleading statements. For instance:

> "The authors considered the condition of saturation of the surface from an immediately preceding storm, but did not mention the possibility of there being appreciable flow already in the stream. The theoretical absolute maximum resulting from the latter condition is double the value computed, assuming that a second storm of equal intensity and duration followed immediately after the storm for which computations were made."

It should also be stated that the writers considered many other "conditions" than "saturation of the surface from an immediately preceding storm" (see "Factor *C*, The Run-Off Coefficient" in Part I) and that the assumptions and hypotheses, on which both the rational method and the proposed formulas are based, do not eliminate from consideration "the possibility of there being appreciable flow already in the stream." Assume, for simplicity of visualization, that the run-off coefficient is constant, and that a storm of uniform intensity occurs over the entire area throughout its time of concentration. The theoretical rate of discharge at the outlet will increase, from zero at the beginning, more or less gradually (depending on the manner of concentration) to a peak at the end of the time of concentration. Consider, further "that a second storm of equal intensity and duration" (and similarly covering the area) follows immediately after the first (that is, the rate of precipitation is continuous). The "theoretical absolute maximum" rate of discharge at the outlet will be identical with (not double) that of the peak of the first storm, and will be a continuation thereof until the end of the precipitation. Much water will be in the channels at the beginning of the second storm, increasing in quantity from zero at the remotest part of the area to a maximum at the outlet.

Of course, in an actual stream, there may be water running due to springs, seepage, or other causes. If so, provision for it may be made, but the illustration suffices to disclose the error in Mr. Lee's statement. He refers to a former writing,[60] in which occurs a listing of various conditions affecting the value of the run-off coefficient. No where in this listing, nor in the curves and diagrams of Mr. Sherman's former contribution,[61] together with accompanying recommendations for their use, is there evidence of any provision for the utilization of the principle of Conclusion 12, ("Factor *C*, The Run-off Coefficient," in Part I), one of the most important considerations of the run-off problem. With this in mind the first three paragraphs of Mr. Reeves' discussion should, indeed, be appreciated.

Mr. Sherman states that: "Although it is somewhat lengthy, the rational method is a simple process of computation * * *." True, the process has been made (in many cases) to appear so simple that long and tedious calculations were often made and supervised by individuals who understood little concerning many of the fundamentals.

The writers are appreciative of the statements contained in the discussion by Mr. Bates, to the effect that: (*a*) The writers presented an original method for estimating storm-water run-off, based on fundamental conceptions and rational conclusions; and (*b*), the formulas are flexible and contain factors heretofore neglected, and are not complicated beyond practical use.

The writers cannot agree with Mr. Bates, however, that the "greater value" of the proposed formulas lies in their use, in conjunction with the empirical formulas, to obtain "*C* values." (Turn to the five statements, (*a*), (*b*), (*c*), (*d*), and (*e*), under "Inadequacy of Empirical Formulas," in Part II.) Consider that Mr. Bates has specialized on the type of rainfall curve and on values of *F*, *P*, and *L* (the length for a given area). There is no way for any one to determine that the values given these factors correspond to those found through experimentation by McMath. Furthermore, an infinite number of "*C* values," would be possible through changes in values of the various factors, and the resulting uncertainty due to the lack of definite information in the records of experimentation leading to the compilation of any one empirical formula would be tremendous.

It should be realized that correct values of the run-off coefficient may be obtained only through direct experimentation, with all conditions known.

The substance of a few selected statements, which convey erroneous conceptions on the part of the author, is recorded in the following citations from Mr. Bates' discussion:

(*a*) The possibility of using the empirical formulas as "yardsticks," by which to measure the writers' formulas;

(*b*) The suggestion that Factor *P* be given a constant value, and the inference that the shape of the area has no significance;

(*c*) The suggestion that, in using a rainfall curve, the designer must assume that the individual storm follows the law of the curve;

(*d*) The suggestion that Table 3 is mis-named, and that the value of *P* has no significance when the storm is one of uniform intensity; and,

(*e*) The idea that the run-off coefficient could not increase due to a higher intensity because of its relation to R_1 of Equation (29).

---

[60] *Transactions*, Am. Soc. C. E., Vol. 93 (1929), p. 433.

[61] *Municipal and County Engineering*, June, 1924.

These points have been so completely covered in the original paper that more elaborate discussion seems unnecessary.

The discussion by Mr. Tapley presents in a more mathematical manner some phases of the factors, that were introduced in the paper. Some of his approaches should help to make the derivations clearer to certain readers. It was the desire of the writers throughout to give the minimum space to all developments in the paper, consistent, of course, with clarity.

It is believed that the logic in the introduction of Factor P (as developed in the paper) will be obvious to the average engineer. It should be noted, of course, that in the "Nomenclature" (Appendix I), the definition of v is given a twofold meaning; and that, while in Equation (18) it is used in the general hydraulic sense, it naturally assumes the specific rôle of the average velocity when used in the run-off formulas.

Mr. Tapley's approaches to Equations (36) and (39) differ from those of the writers. While his manner of arriving at Equation (36) may be clearer than the original to some readers, the assumptions made in his derivation of Equation (39) may be misleading.

Consider a water-shed in which, for example, there exists, scattered over the area, certain depressions or cavities, which are capable, at a given instant, of retaining the precipitation falling thereon.

Visualize a process of concentration of the water resulting from a given intensity which lasts as long, or longer, than the time of concentration of the water-shed. The discharge at the outlet at a given instant, being composed of precipitation that fell at different specific times, represents contributions from the various parts of the area. Another discharge occurring immediately before, or after, represents precipitation that fell at other specific times. Hence, the rate of run-off at the outlet is a combination of contributions, from the various parts of the water-shed, as of the specific times precipitation occurred thereon. The storage factor, m, is represented by the quotient, the rate of withdrawal due to depressions, or cavities, divided by the rate of precipitation. When the precipitation is unevenly distributed with regard to area or time, Factor m must be regarded as a percentage of the average rate of precipitation for the time of concentration.

While z is a rate, m is the percentage of a rate. The product, mi (a rate) must be regarded as a distinct loss, deductible from the rate of precipitation, i, in the process of calculating the outlet discharge for a given instant of time. If m is defined as "the percentage of (i-z) stored" (as Mr. Tapley suggests), the meaning would be that the precipitation, falling in the depressions or cavities, consists of two parts—storage and absorption plus evaporation. If m is defined as a "retardation factor," as in the discussion by Mr. Bernard, the proper and full meaning is not conveyed.

The nomenclature of the paper, therefore, should be retained. It should be noted that the area, A, was used for the purpose of enabling better visualization.

For the values of the run-off coefficient, C, Professor Powell presents the expression, $iA - miA - zA$ (or $1 - m - \frac{z}{i}$). Having deducted, in miA, all the precipitation falling in cavities and depressions, he would subtract an additional amount, mzA. His expression is, of course, in error.

Mr. Grunsky states,

> "It appears obvious that of the total quantity of water falling on a water-shed as rain, the relative quantity which evaporates, together with that which sinks into the ground and is thus prevented from contributing to the peak discharge, increases as the critical time (that is, as area) increases."

In order to comprehend the meaning of the statement one must visualize two water-sheds, with similar physical characteristics, one being larger and with a consequent longer time of concentration. Each must be capable of concentrating the water, else there could be no opportunity for measuring a "peak discharge." Visualize, again, a process of concentration for each water-shed, as outlined in the foregoing discussion of Factor m. Assume, for simplicity, that each water-shed receives the same intensity during the times of concentration. For the consideration of the peak rate of discharge for either water-shed "the quantity of water which evaporates, together with that which sinks into the ground," is an average rate (deductible from the rate of precipitation), and not a volume multiplied by units of time. It is an average of the rates of loss of each elementary area, as of the specific instants each such area contributes to the peak run-off. Outside the effect of loss through evaporation and percolation in drainage channels (in one area as compared with the other), the only basis for judging such relative rates, of the two water-sheds, would be the average condition of wetness of their respective elementary areas.

It is clear that for like intensities of precipitation the elementary areas of the larger water-shed, on the average, would be more thoroughly saturated (at the instants of contributing to the peak discharge), and that the average rate of loss for it would be lower (not greater) than for the smaller one. It is conceded, of course, that the smaller water-shed, because of its shorter time of concentration, may be expected to receive a higher average intensity than the larger one. Since, as the writers have shown ("Factor C, the Run-Off Coefficient," in Part I), that, other conditions being constant, the run-off coefficient is increased by an increase in intensity, Mr. Grunsky's factor, a, for the larger water-shed would tend to be less than for the smaller one. Hence, if it be assumed that the effect of a greater average wetness of the larger water-shed balances that of a higher relative intensity on the smaller one, the factor, a (being Mr. Grunsky's notation for a run-off coefficient), would be constant with respect to time.

His statement (referred to in the foregoing) does not "appear obvious" in the light of analysis. No reasonable basis for Equation (112) has been demonstrated.

Mr. Grunsky writes again of water "temporarily stored in transit" in the channels and on the ground. Other engineers have suggested the possible alteration of the times of concentration and discharges, as rendered by the writers' formulas, due to the effect of such waters "temporarily stored in transit." It should be stated that the hypotheses, on which the writers' formulas are based, not only admit of, but make imperative, the existence of water on the ground and in the channels both before and after the arrival of the peak discharge. The water in transit in the channels is not stored, but is flowing toward the outlet where it forms a rate of discharge at each instant of time, before, at, and after, the arrival of the peak rate—hence, a hydrograph. Since each such rate of discharge is a combination of contributions from various parts of the water-shed as of the specific instants precipitation occurred thereon, the quantity delivered at each instant is, fundamentally, independent of the water flowing immediately before or after, except that it is supported in position by these other quantities.

The time of concentration, considered in developing the formulas, is not based on the time of flow of a single drop of water from the remote part of the water-shed to the outlet, but rather on that of the flow of the body of water in the main, or time-rendering channel (defined in the paper), as determined by the hydraulic formula used. Kutter's formula, for instance, is based on the average velocity of the full cross-sectional area of the channel. To make material additions to, or deductions from, the times of concentration or discharges, as determined properly by the formulas, because of an imagined storage in the channels, would be a mistake. It makes no difference, fundamentally, whether the channels are large, or small, or whether they are conduits, or rough and open channels. These are hydraulic considerations that influence the choice of factors for use in the formulas.

A statement that is more or less typical of many advanced by discussers, is contained in the discussion by Mr. Hicks, that is, "in the derivation of the formula, the factor, F, is based on the conduit running full. * * *." The derivation of Factor F is, of course, independent of the run-off formulas, and the values in Table 11 do not depend on any assumptions regarding intensity distribution. While Table 11 may be incomplete to some extent, facilities are already provided (in the combined two main divisions, "Closed Sections" and "Open Sections") for the consideration of both full and partly full conduits. While confusing purely hydraulic considerations with special assumptions and methods necessitated by the detail process of the rational method, Mr. Hicks assigns, erroneously, certain limitations to the run-off formulas.

In his discussion, Mr. Hickox presents a problem, which, he states, "may be taken as a fair example for comparison of rational and empirical formulas;" that is, the solution for the run-off of the Iowa River Basin above Iowa City. Comparative run-off results are given for two groups of assumptions, which, he states, are based on the "50-year rainfall intensity" and the "maximum precipitation," respectively. Unfortunately, few data for qualifying his assumptions are given, and the details of the solution by Equation (24) are omitted.

In the solution for each set of assumptions, Mr. Hickox arbitrarily assumes 100 hours for the time of concentration. This time has no bearing on the solution by Equation (86) and is incorrect for the assumptions used in solving by Equation (24).

In the first instance, if it is known, as given by Mr. Hickox, that $i = 0.0555$, that $C = 0.35$, and that $A = 3\,140 \times 640 = 2\,009\,600$ acres, no run-off formula is needed. From Equation (1) $Q = CiA = 0.35 \times 0.0555 \times 2\,009\,600 = 39\,036$ cu. ft. per sec.

Mr. Hickox could have ascertained times of concentration for his assumptions through Equation (24). For instance, solving by the "50-year rainfall intensity" formula (and using Mr. Hickox's assumptions), $t = 117.94$ hours.

Regarding the solution by the second set of assumptions Mr. Hickox states, "the maximum average precipitation on the Iowa River Basin is probably about 10 in. in 4 days, or approximately 0.1 in. per hour for 100 hours." If the precipitation is 0.1 in. per hour for a period of 4 days (or for 100 hours), it would not necessarily be 0.1 in. per hour for the time of concentration, when based on the assumptions for the water-shed.

Assume that the average intensity is 0.1 in. per hour for 4 days (96 hours, or 5 760 min.). Using Equation (2), with $e = 0.8$ and $t = 5\,760$ min., multiply by the reduction factor, 0.78, and solve for K; then, for R_1, $R_1 = 3.005$. In Equation (24), let $e = 0.8$, $H = 1$, $R_1 = 3.005$, $C = 0.4$, and use the same values for the other factors as in the preceding solution. There results, $Q = 59\,360$ cu. ft. per sec., average $i = 0.074$ in. per hour, and $t = 103$ hours.

Note (*a*) that the time of concentration, as rendered by Equation (24), for the first group of assumptions is 117.94 hours, while that for the second set is 103 hours; and (*b*) that the use of Equation (24) automatically gives the time of concentration and corresponding intensity. Note, further, that Mr. Hickox's value for the run-off (84 400 cu. ft. per sec), resulting from the second set of assumptions, is greatly in error, and that his corresponding conclusion is likewise incorrect.

Mr. Hickox's discussion failed to recognize the following points, which should be stressed: (*a*) The formulas, instead of rendering what he terms "the absolute maximum," may be used with any frequency period as determined by the particular rainfall curve; (*b*) the assumptions and data concerning precipitation must be incorporated in the rainfall curve, not in a formula; (*c*) the formulas may be used to apply to a part of the water-shed as well as to the whole; and (*d*) one of the main purposes of the formulas is to serve as an aid in determining times of concentration and average intensities.

The discussion by Mr. Baker conveys a broad understanding, on the part of the author, and is well worth reading.

The writers are in agreement with Mr. Baker that the run-off coefficient is of vital importance to the run-off problem, even when viewed from the strictest economical standpoint; and that more and better experimentation is needed. It is also reasonable, as Mr. Baker suggests, that governmental agencies, capable of broad experimentation over extended periods of time, would be most suitable for the purpose. Moreover, when one reviews the existing conflicting data on this factor, the lack of thorough analysis (which indicates incomprehensive visualization during experimentation) is very evident. Experimentation and intelligent analysis must be co-ordinated — some capable individual must be willing to "marry the job"—if worth while results are to be obtained.

In his Equation (91), Mr. Baker treats of one of the effects of slope on the absorptive powers of soil, namely, that of the head of the water in transit. Another possible effect of a difference in slope on absorption (other influences being constant) is the disturbing action and motion of a higher velocity, as compared with the effect of a lower one, on the soil. This action would tend to balance (or, possibly, more than balance) the effect due to a difference in head.

It should be pointed out that in deriving Equation (91) Mr. Baker assumes that percolation varies directly as the superimposed head. For porous soils percolation would take place according to Darcy's law, or would vary directly as the head; but the head should be measured from the top of the water to the bottom of the soil, assuming the water has a free outlet (say, into coarse gravel). (As an example to illustrate this statement, see Fig. 4 of a paper[62] entitled "Soil Mechanics Research" by Glennon Gilboy, Jun. Am. Soc. C. E.) Thus, Mr. Baker's z'' would equal $k''(d + d')$, in which d' equals the soil depth, and Equation (91) becomes complicated to an extent that would alter materially Mr. Baker's subsequent conclusions.

For all ordinary soils the practical effect of a difference in slope on percolation in its extent of influencing run-off is small as compared to that of other physical characteristics. An idea concerning the effect of superimposed head on percolation may be gained from a consideration of the findings in the Miami Valley by Ivan E. Houk, M. Am. Soc. C. E. He found[63] that the value of his symbol, b, for the Miami Valley, would be between 0.25 and 0.30 in. per hour for the summer and fall when the ground is saturated. Assume that the soil depth is 4 ft. to gravel deposit and that percolation is 0.3 in. per hour with no superimposed head. For a superimposed head of 6 in., the percolation would be $\frac{4.5}{4} \times 0.3$, or only 0.34 in. per hour, if it varied directly as the hydraulic head.

In actual water-sheds the water is not long in finding its way into natural or improvised channels, which form a relatively small part of the total area. The average depth of a sheet of water over a pervious area is not likely to be great for the heaviest of rains, except in very unusual circumstances. That part lying in depressions, which fail to contribute to the collection of waters forming the peak run-off at the outlet of the water-shed, is cared for by m of Equation (39).

Answers to Mr. Jarvis may be segregated into four parts, as follows:

(1) Some of the answers will be found under the heading, "General Solution by Equation (29)," in this discussion in connection with Mr. Jarvis' remarks concerning the rainfall curves of Adolph F. Meyer, M. Am. Soc. C. E. It should be noted also that the curves of Mr. Bernard belong to Equation (2), which Mr. Jarvis says "the rational method should exclude."

(2) The writers feel that Mr. Jarvis' citation concerning Equation (32) is far fetched.

---

[62] *Proceedings*, Am. Soc. C. E., October, 1931, p. 1165.

[63] "Rainfall and Run-Off in Miami Valley," Technical Repts., Pt. VIII, 1921, pp. 121–126.

(3) There is nothing in Example (3) (or any other examples of the paper) to indicate: (*a*), that the writers "seem to be carrying the storm drainage conduits throughout the water-sheds" with natural drainage systems; and (*b*), that the instantaneous discharge at a given section should vary directly with the length of travel. The high value of F (causing the velocity of 28.3) was chosen arbitrarily to illustrate a point in hydraulics, and the example is in itself no part of the solution for the run-off of a water-shed either with natural or artificial channels. In deriving their formulas, the writers used both the linear dimension, L ("some function of the drainage area"), and the "average width."

(4) Instead of selecting factors for use in examples for the purpose of indicating their judgment, the writers endeavored to illustrate methods of procedure; and ample facilities have been provided for exercise of the engineer's judgment in making such selections.

The opening paragraph of Mr. Bernard's discussion is indicative of his understanding and attitude. He has pursued a constructive course, and, doubtless, the engineer will find much of value in his contribution.

Mr. Longacre contributed a discussion that should prove of real value to many engineers. Considering the approximate nature of the run-off problem, with its many possibilities for variations in assumptions and data, the nomograph (Fig. 9) will be found accurate enough for the usual problem. As stated by Mr. Longacre, a nomograph "can readily be constructed for a curve of any of the general types in present use." This is unnecessary, however, since Fig. 9 (or any good nomograph of Equation (29)), may be used in conjunction with the simple method of transition, which the writers are introducing under the heading, "General Solution by Equation (29)," in this discussion. Mr. Longacre's Fig. 11 will also prove of value for general hydraulic purposes.

General Solution by Equation (29).—Under the headings, "Special Reduction of Equation (24)," and "Remarks Concerning Examples 6, 7, 8, and 9" (Part II), it was shown that Equations (28) and (29) could be used for the purpose of approximating closely the run-off result for any type of rainfall curve.

It should be observed that Equation (28), or Equation (29), served to obtain the time of concentration for a given area. This time, being based on the rainfall curve expressed by Equation (3), results from the application of a definite ordinate thereof (or a definite average intensity) to the water-shed. The ordinate of another curve (used to obtain the corrected Q), would cause a somewhat longer or shorter time, depending on the divergence in value of the ordinates of the two curves. The difference in time is due, therefore, to a greater or less average quantity of water running in the main (or time-giving) channel of flow.

After gaining a thorough understanding of the principle involved in making the transition, it may be visualized that the rainfall curve of the type expressed by Equation (3), together with Equation (29), is capable of being used as a scaffold work for the solution of any rainfall curve or group of curves. This method of approach differs from that illustrated in Examples 7 and 9, in that it eliminates the consideration of the variables, R_H and H, or specializes in the values, $R_H = R_1$, and $H = 1$. Two examples will illustrate:

Example 15.—The solid curved line of Fig. 16 is expressed by,

$$i = \frac{235}{t + 26.3} \qquad (134)$$

This curve is fairly representative of the curves of the Meyer[64] group, being arbitrarily selected from Fig. 1 of the paper [65] by Merrill M. Bernard, M. Am. Soc. C. E., entitled "Formulas for Rainfall Intensities of Long Duration."

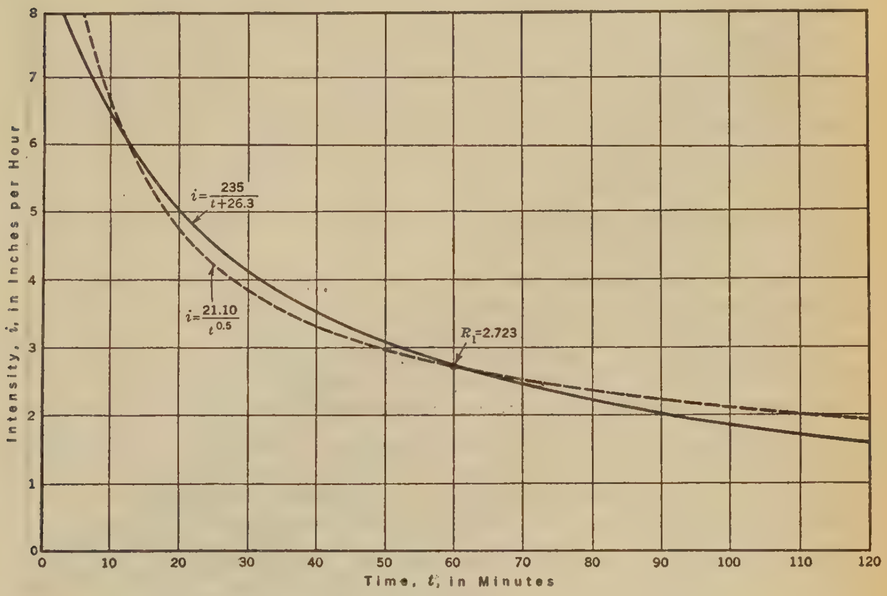

FIG. 16.

The dashed line is expressed by Equation (3) reduced. In superimposing the dashed curve the two were placed together at the 60-min. ordinate by solving Equation (134) for R_1 (= 2.723), with $t = 60$ min. Note that the divergence of the two types of curves is not great at any point between 5 and 120 min.

Suppose that it is intended to solve by the use of the curve expressed by Equation (134), and that the following factors have been determined: $A = 1\,000$ acres; $L = 14\,700$ ft.; $S = 10$; $F = 6.0$; $C = 0.4$; $P = 0.5$; and R_1 being, of course, 2.723.

Solve for the time of concentration by Equations (29) and (26), as illustrated by Example 8, or directly by nomograph of Equation (29) similar to that presented by Mr. Longacre.

---

[64] "Elements of Hydrology," 1928.

[65] See p. 595.

The time is found to be 28.7 min., the corresponding ordinate of Equation (134) is, $i = 4.27 +$; and (substituting in Equation (1)), $Q = 0.4 \times 4.27 + \times 1\,000 = 1\,709$ cu. ft. per sec.

Merely to test the accuracy of the solution, the problem is solved by two trials (as illustrated in Example 13), the actual Q resulting from the direct use of Equation (134) being 1 726 cu. ft. per sec. The accuracy of the "scaffold work," in this case, is within 1%, or $\frac{1\,709}{1\,726} = 0.99 +$.

Example 16.—This example illustrates the application of Equations (3) and (29) as a "scaffold work" for the solution of a group of curves.

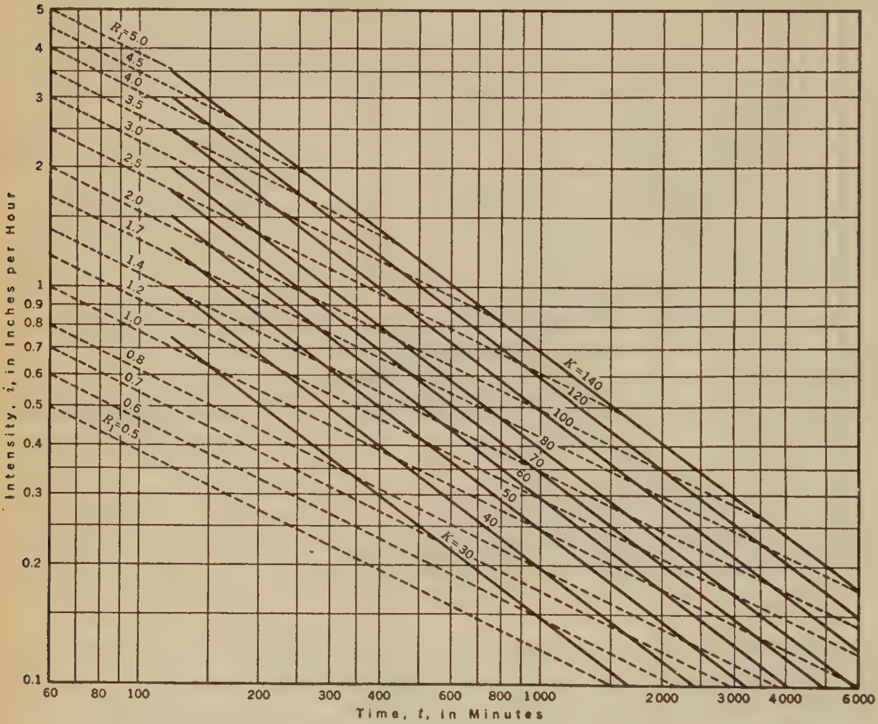

FIG. 17.

The solid and dashed lines of Fig. 17 are expressed by Equation (2) with $e = 0.77$ and 0.5, respectively, and with varying values of K, the time being in minutes. It may be noted that the value of e for the solid lines is approximately the average of the exponential values shown by Mr. Bernard in his paper, entitled "Formulas for Rainfall Intensities of Long Duration."[86] The dashed lines form the "scaffold work" of Equation (3) with varying values of K (and, consequently, R_1), t being expressed in minutes.

---

[86] See p. 592.

Assume that it is desired to solve by the equation,

$$i = \frac{80}{t^{0.77}} \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (135)$$

shown on Fig. 17, the factors being (with the exception of R_1); $A = 500\,000$ acres; $L = 400\,000$ ft.; $S = 4.0$; $F = 4.5$; $C = 0.3$; and $P = 0.5$.

The solution for the time of concentration may be made by Equations (29) and (26) (or by nomograph as Fig. 9) and transition to the line representing Equation (135), when the approximate proper value of R_1 of Equation (3) is known. To ascertain the value of R_1 to use, make a rough assumption for the time of concentration of the area, say, 6 to 12 hours, or 360 to 720 min. The dashed line (of Equation (3)), which crosses the solid line, representing Equation (135), during this time period, leads to $R_1 = 2.0$. Solve by Equations (29) and (26) (or nomograph thereof). The time is thus found to be 644 min. Opposite this time on the line for Equation (135), Fig. 17, the intensity is, $i = 0.55$, and, Equation (1) gives $Q = 82\,450$ cu. ft. per sec.

To test the accuracy of the solution (this would be, of course, unnecessary in practice) solve by Equation (24), in which $e = 0.77$ and, since $i = \frac{80}{t^{0.77}}$, $R_1 = \frac{80}{(60)^{0.77}} = 3.42$. The resulting Q is 80 091 cu. ft. per sec., the value of i from Equation (1) is 0.534, and the value of t from Equation (26) (or Fig. 17) is 669 min. The accuracy of the "scaffold work" for estimating the run-off in this case is represented by $\frac{82\,450}{80\,091} = 1.03 -$. Thus, for a very rough assumption for the time of concentration (from 6 to 12 hours), made for the purpose of selecting a value of R_1 from the "scaffold work," the resulting Q was found to be within 3% of the accurate solution by Equation (24) reduced.

The second solution could be made by Equation (29) and "scaffold work" (by choosing a new value of R_1 for the dashed line that crosses the line for Equation (135), at the time for the first trial), which would reduce the error to insignificance. Although a second solution would always indicate the degree of accuracy, it would be unnecessary for experienced estimators when using a "scaffold work" as Fig. 17.

Two concluding observations should be made:

1.—For times of concentration, from 5 to 120 min., solutions may be made for all rainfall curves in present use, through Equation (29) and transition as outlined herein, without recourse to a "scaffold work" in graphic form; that is, by simply using the R_1 of the adopted curve.

2.—Solutions for any curve, or group of curves, may be accomplished, with a high degree of accuracy, through the use of Equation (29) and "scaffold work" of Equation (3).

GRAVITY DAMS ARCHED DOWN STREAM[1]

BY B. J. LAMBERT,[2] M. AM. SOC. C. E.

WITH DISCUSSION BY MESSRS. EUGENE KALMAN, WILLIAM P. CREAGER, T. L. E. HAUG, B. F. JAKOBSEN, A. FLORIS, FLOYD A. NAGLER, AND B. J. LAMBERT.

SYNOPSIS

When a canyon site seems best adapted to a gravity type of dam there is some question as to the desirability of arching it in an up-stream direction. The writer advocates the straight gravity dam for certain sites as, for example, the St. Francis Dam, and presents further arguments to support his theory that in some situations a dam curved down stream may be preferred to the other two types.

The writer has not seen, in discussions on high, curved, gravity dams in canyons, any reference to the relation of the curvature of the dam to the slopes of the side walls. He has been interested in this problem for a number of years, particularly since the failure of the St. Francis Dam in March, 1928. Fig. 1 shows a concrete model of this dam built to a scale of $\frac{1}{240}$, or 1 in. = 20 ft., in a trough made to resemble, roughly, the valley at the site. This trough was made of planking as shown.

The model was formed in place. It had a base of about 8.25 in., a height of 10.25 in., and a cross-section similar to that of the St. Francis Dam, with the exception of the heel on the lower 20 ft. The radius of the arch was 500 ft., or, for the model, 25 in. Sections and elevations of a dam illustrating a supplementary feature are given in Fig. 2. This feature is described in another part of this paper.

Assume that the dam acts as a unit, instead of treating each foot in length as a gravity dam. In the model it is readily seen that, if the dam overturns, it will turn about a part of the toe at the deepest section. The toe along the slopes may be under no pressure when the dam starts to overturn, but the sloping ends of the dam are hanging as cantilevers on the central part of the structure. Consider that the curvature of the dam and the slopes of the canyon walls are such that the extreme ends of the dam are in front of a vertical plane passing through the toe of the highest section. Then if the dam begins to overturn the greatest pressure will come first upon these extreme ends, and the remainder of the toe will be under smaller pressures.

---

[2] Head, Dept., Civ. Eng., State Univ. of Iowa, Iowa City, Iowa.

In the model as constructed, the toes at the ends are found to be about 3.5 in. (70 ft.) back of the toe at the deepest section. Had the slope of the canyon walls been somewhat less as shown by the dotted line in Fig. 1(*d*), the ends of the dam could easily have been in front of the toe at the deepest section, in fact, one end was in front of the toe, in the St. Francis Dam.

FIG. 2.—DRAWINGS OF MODEL, ILLUSTRATING USE OF EYE-BARS CHAINS.

The effect of curving the dam causes the center of gravity of the dam as a unit to fall nearer the toe. In the model the gravity center is found to be about 5.1 in. from the toe (see Fig. 1(*c*)) while for a small length of dam at its deepest section the center of gravity is about 5.5 in. from the toe.

Likewise, the center of pressure of water acting on the rear of the model dam is found to be about 4.14 in. above the base, and the total pressure to be about 25.7 lb. If full upward pressure is assumed at the heel, varying to zero at the toe, this will be approximately 22 lb. and will be applied slightly inside the middle third of the base. The model dam weighs approximately 48 lb.

Fig. 3 shows a cross-section of the model dam at the middle. If a center of moments is taken at the toe, it will be found that a push, p_1, of $\left(\frac{48 \times 5.1}{10.25} =\right)$ 23.8 lb. is required at the top to overturn the dam, with reservoir empty. By actual test a force of 24 lb. was required. If applied at the center of water pressure, that is, 4.14 in. above the base, the theoretical force, p, required is $\left(\frac{48 \times 5.1}{4.14} =\right)$ 59 lb. The force as actually measured was about 58 lb.

The resultant of the weight of the the dam and the water pressure is found to cut the foundation about 2.9 in. from the toe. Assuming that a section 7.5 in. wide takes all the pressure at the time of incipient overturning, the unit pressure per square inch on the model at the toe is,

$$p = \frac{2\,W}{L}\left(a - \frac{3\,a}{L}\right)$$

in which, L is the width of the base, and a, the distance from the toe to the resultant. Then, $p = \frac{2 \times 48}{8.25}\left(2 - \frac{3 \times 2.9}{8.25}\right) = 11.0$ lb., if applied over a length of dam of 1 in., and $\left(\frac{11.0}{7.5} =\right)$ 1.47, if applied over 7.5 in. in length.

Since the scale of the model is 1 in. = 20 ft. = 240 in., the stress, p, at the toe in the full-sized dam would be 1.47 × 240 = 350 lb. per sq. in. on a horizontal section, and about 500 lb. per sq. in. if the actual thrust resultant and a plane normal to it are used for the computation. With full upward pressure at the heel, varying to zero at the toe, the factor of safety against overturning about the toe is small, because the resultant comes within about 1 in. of the toe in the model.

The foregoing remarks indicate that if the overturning of the dam occurred about the full length of the toe, at its deep section (that is, 7.5 in. in the model, or 150 ft. in the original dam), the pressure per square inch on the toe would be only 500 lb., which would not cause failure. If the bottom of the dam along this section is not horizontal, however, but is built in a valley the greatest depth of which occurs over a short distance only, the turning might take place over a much restricted length of toe, and the pressures would increase correspondingly. For example, if in the St. Francis Dam, the toe on a section only 50 ft. long carried the full load at the time of greatest stress, the unit pressures might then be 1 500 lb. per sq. in., even with no upward pressure considered.

With upward pressure considered and with the resultant cutting the foundation 1 in. from the toe, the unit pressures as previously determined are,

$$p = \frac{2 \times 48}{8.25}\left(2 - \frac{3 \times 1}{8.25}\right) = 19 \text{ lb. per sq. in.}$$

If applied over the center section (7.5 in. wide at the toe), this would give more than 2.5 lb. per sq. in. on the model, or 2.5 × 240 = 600 lb. per sq. in., on the section horizontal to the thrust, and 850 lb. on the section normal to the thrust.

The section of the St. Francis Dam left standing was only about 90 ft. long. If this represents the length of base on which turning might have occurred, the unit stresses on the toe may have been sufficient to cause failure by crushing at the toe. This may have caused the beginning of the overturning. The end portions would then break off, due to water pressure and the weight of the concrete, as they were lifted from their base. As they turned about the portion of the base left standing the pressures on the front due to this hinge and the toe pressures already mentioned spawled off the large masses of concrete, as shown in photographs of the failure.[3] The values in this paper are necessarily approximate, but they are thought to be sufficiently accurate to justify a belief that the dam might have failed even if it had been built on granite foundations.

The writer believes that a straight gravity dam would have been preferable to the curved one as built. He will go one step farther and state that a dam arched down stream (Fig. 1(*b*)) would have been even better for this location.

A concrete model of this type of dam was built at the same time as the model in Fig. 1(*c*). The same gravity section was used and the same radius of curvature. The models weighed practically the same, within a few ounces, and an analysis of the two volumes seems to show practically equal quantities of materials required for the two conditions. (See Figs. 1 and 4.)

In the model with its back down stream, however, the center of gravity was about 6.75 in. from the toe (see Fig. 1(*b*)). In consequence, the resultant of the total water pressure on the rear and the total weight of the dam cut the base back of the mid-point, and the unit pressures under any of the conditions assumed in the foregoing example were materially reduced.

Theoretically, a force, P, of $\left(\frac{48 \times 6.75}{4.14} =\right)$ 78 lb., is required at the center of pressure to overturn this dam about the toe. In the model, about 80 lb. was required. This, compared with the water pressure of 25.7 lb. on the back of the model, gives a factor of safety of about 3, if upward pressure is neglected.

In the case of the dam with its back up stream, the factor of safety under the same conditions is about 2.3; but with an upward pressure varying from full load, *wh*, at the heel to zero at the toe, the dam with its back up stream has practically no factor of safety, while the one with its back down stream still has a factor of safety of more than 1.5.

---

[3] *Proceedings*, Am. Soc. C. E., October, 1929, Papers and Discussions, p. 2157.

It is also to be noted that if a radial section is studied, its base, in the case of a dam arched down stream, slopes up toward the toe; while in the case of the dam the arch of which is up stream, the base slopes down toward the toe. The amount of this slope varies from about 35 ft. at the deepest section to, say, 6 or 8 ft. at the ends.

It is presumed that the water pressure on a gravity dam arched up stream will tend to close any shrinkage cracks, the sections acting as voussoirs of an arch. It might seem as if the dam that was arched down stream would have a greater tendency to open up along shrinkage or construction joints than if it was curved the other way. The writer can scarcely concede even this when it is observed that the entire dam is much more stable, and any radial unit must be tipped up-hill to cause failure. The wings tend to tip against the walls of the canyon when the back of the arch is down stream, instead of tipping into the canyon as is the tendency when arched up stream.

A model of a straight gravity dam was also built (see Fig. 1(*a*)), and was found to be somewhat more stable than the dam arched up stream (Fig. 1(*b*)), and considerably less stable than the one arched down stream (Fig. 1(*c*)). In all cases, the overturning pressures were applied at the center of pressure through a bent hook and a standardized spring balance, using a horizontal pull.

The writer is strongly of the opinion that, before any definite design for a dam in a canyon is accepted, relatively large models of the actual canyon, with its actual foundation profile, and of the proposed dams and footings, should be made and studied. Had this been the practice in the past it is thought that quite likely some of the accepted designs might have been considerably modified, or the footings and abutment conditions materially changed.

It will be observed that the basis of this study is an assumption that, in general, the dam will act as a unit. Construction and shrinkage cracks cannot be eliminated, but the sections will interlock more or less, and certainly will be of large size, as illustrated by the central block of the St. Francis Dam which was left standing after the disaster.

Another suggestion that could be applied to the arched dam with its back down stream is illustrated in Fig. 2. Consider the St. Francis Dam, for example, and assume the curvature reversed. Fig. 2(*b*) shows the dam built up to a height of, say, 75 ft. At this elevation place an eye-bar suspension chain of any cross-section desired, and anchor it at each end into down-sloping tunnels in the canyon walls. After the chain is placed, and the ends are anchored, jacking pressure could be applied to a saddle at its center, and any predetermined initial stress could be maintained while concrete is being placed over the cable. As many cables or chains as desired could thus be placed at such elevations and of such cross-section as would be found most satisfactory. A small percentage of the cost of the dam thus expended in steel (preferably of high tensile strength), would increase the factor of safety both against overturning and sliding.

It seems reasonable to assume that the quantity of concrete could be reduced to such an extent as to pay for the steel and still have a safer dam. It could scarcely be said that these eye-bar cables would act as tensile reinforcement to tie the large blocks of the dam together, because the percentage of steel compared with the quantity of concrete would necessarily be small. However, picture a chain of, say, ten eye-bars, each with a section of 12 by 2 in. (240 sq. in. in all), made of a steel with an ultimate capacity of 100 000 lb. per sq. in., or more. With such a chain, requiring a force of 24 000 000 lb. to break it, one might be justified in expecting that the larger segments of a dam would resist separation for some time.

All this may seem unorthodox, but no harm and, perchance, some benefit may result from a discussion of the proposals herein outlined.

DISCUSSION

EUGENE KALMAN,[4] M. AM. SOC. C. E. (by letter).—This extremely interesting paper is a revelation, inasmuch as it calls attention to the fact that a gravity dam with sloping wings might be subjected to tensile stresses even if, theoretically, all the individual vertical cantilever slices were safe against such stresses. In other words, the resultants of the forces acting on the individual cantilever slices may fall within the middle third of their respective bases, and the resultant of the dam as a whole may fall outside the middle third of the base.

This is due to the effect of the sloping wings. A brief analysis of stress conditions will be given in this discussion. Consider a straight gravity dam with a constant section. The total bending moment due to water pressure and the weight of the dam with respect to the heel will be:

$$M = \frac{1}{6} H^3 (2 \gamma_c \tan^2 \beta - \gamma_w) d \quad \text{(1)}$$

in which, H equals the height of the dam; d, the width of the horizontal canyon bottom, corresponding to the height, H; γ_w, the specific weight of water; and γ_c, the specific weight of concrete. The down-stream face of the dam has a slope of 90° — β, and the up-stream face is vertical. Furthermore, let the slope of the wings equal 90°—α, and let x equal the horizontal distance of an elementary cantilever slice, dx, from the bottom of the slope of the wing toward the top. The bending moment of the cantilever slice with respect to the heel at the depth, H, may be computed as follows: The height of any cantilever slice may be expressed by the equation:

$$h = H - x \cot \alpha \quad \text{(2)}$$

The total water pressure acting on this slice is equal to:

$$p_w = \frac{1}{2} \gamma_w (H - x \cot \alpha)^2 \, dx \quad \text{(3)}$$

The lever arm of this force with respect to the bottom is,

$$y = H - \frac{2}{3} (H - x \cot \alpha) = \frac{1}{3} (H + 2 x \cot \alpha) \quad \text{(4)}$$

and, hence, the moment due to water pressure on the cantilever slice will be,

$$M_2 = \frac{1}{6} \gamma_w (H - x \cot \alpha)^2 (H + 2 x \cot \alpha) \, dx \quad \text{(5)}$$

The cantilever under consideration with a height, h (see Equation (2)), and a thickness at the base equal to,

$$b = (H - x \cot \alpha) \tan \beta \quad \text{(6)}$$

has a dead weight of,

$$w = \frac{1}{2} \gamma_c (H - x \cot \alpha)^2 \tan \beta \, dx \quad \text{(7)}$$

---

[4] Visiting Prof., Civ. Eng., California Inst. of Technology, Pasadena, Calif.

The lever arm of this force with respect to the heel line of the central portion of the dam is expressed by the equation,

$$y' = H \tan \beta - \frac{1}{3} (H - x \cot \alpha) \tan \beta = \frac{1}{3} (2 H + x \cot \alpha) \tan \beta \ldots (8)$$

Therefore, the moment due to the weight of the cantilever slice will be,

$$M_3 = \frac{1}{6} \gamma_c (H - x \cot \alpha)^2 (2 H + x \cot \alpha) \tan \beta \; dx \ldots\ldots\ldots (9)$$

The total moment due to the forces acting upon the cantilever slice is the sum of Equations (5) and (9), that is,

$$M = \frac{1}{6} (H - x \cot \alpha)^2 [(- \gamma_w + 2 \gamma_c \tan \beta) H$$
$$+ (- 2 \gamma_w + \gamma_c \tan \beta) x \cot \alpha] \, dx \ldots\ldots\ldots\ldots\ldots\ldots (10)$$

The moment of all the forces acting on the two wings will be twice the moment indicated by Equations (5), (9), and (10), respectively, with x changing from 0 to $H \tan \alpha$, which is expressed by,

$$M = \frac{1}{12} (3 \gamma_c \tan \beta - 2 \gamma_w) H^4 \tan \alpha \ldots\ldots\ldots\ldots\ldots (11)$$

The moment of all forces acting on the dam, taken about the heel line of the central part, is equal to the sum of Equations (1) and (11).

The sections of the dam are free from tensile stresses if the resultants are assumed to pass through the down-stream kern points of the base section; that is,

$$\gamma_w = \gamma_c \tan^2 \beta \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (12)$$

Hence, it is apparent that Equation (11) is always positive and that the whole dam constructed on this basis will never be in danger of overturning. However, tensile stresses are present in the central part. If β is chosen according to Equation (12) so that the resultant of the forces on all cantilever sections passes through the down-stream kern point at the base of all individual elementary cantilevers, it is obvious that the continuation of the resultant of all wing sections will fall outside the middle third of the central section, thus indicating the presence of tensile stresses in the central part of the dam when considered as a whole.

The foregoing analysis is based on the assumption that the wings will not be influenced by any load except their own weight and the water pressure. This means that there is no interaction between wings and foundation, or, in other words, that the wings are not supported by abutments at all. In such a case the single vertical cantilever elements of the wings will have a tendency to deflect as a whole directly down stream. Such deformation creates horizontal shearing stresses along the vertical cut faces of the individual cantilever slices, and these shearing stresses directed down stream, constitute an additional load acting with the water pressure on the central cantilevers, thus increasing the flexure of these longer elements and, consequently, introducing tensile stresses.

Conditions are quite different if there is real interaction between the wings and the foundation as may be expected in every practical case. The elementary wing cantilevers (Fig. 5(*b*)) may be considered identical with the upper end portions of the full central cantilevers (Fig. 5(*c*)), both from the point of view of their geometrical shape and from their loading. Therefore, it is obvious that the wing sections are subjected to smaller flexural down-stream deflections than the central section. Furthermore, there is no greater danger of sliding in the wing cantilevers than in the central cantilevers, since the unit horizontal thrust at all heights is proportional to the weight of the concrete column resting on the unit horizontal area. Under these conditions there is no reason why the wing cantilevers should begin sliding sooner than the central full-sized cantilevers since the former are subjected to smaller flexural deformations than the latter. In other words, it cannot be expected in a practical case that the wings will deflect more than the central part either because of flexure or sliding. On the other hand, this means that the wings cannot create horizontal shearing stresses directed down stream in the central part of the dam. Quite the contrary; the wings deflect less than the central part and, therefore, they help to decrease the bending in that part, and improve its stability.

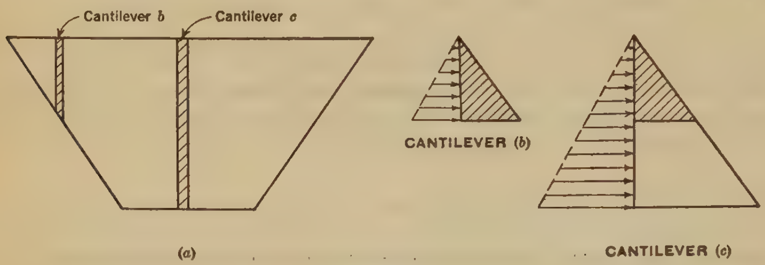

Fig. 5.

Furthermore, assuming wings that are not supported by abutments, it is clear for the reasons given by the author that the gravity dam arched down stream is more efficient than the one arched up stream. This fact is entirely consistent with good theory. It seems paradoxical to state that an arch curved down stream is more resistant than one curved up stream, but, in the present case, the latter does not refer to a string polygon in compression and the former does not refer to a string polygon in tension, since the end forces of the string polygon, which are generally determined by the end reactions at the restrained end abutments, are missing in this case. The individual horizontal arch slices are, in the present case, subjected to flexure and not to tension or compression. Hence, despite the characteristic geometric shape of the structures, they cannot be termed arches or catenaries, since there is no catenary action.

The experiments made by the author are perfectly convincing for the case of free wings. On the other hand, they do not represent actual conditions, because of the lack of structural unity between the wings and the foundation.

There is no adhesion between the concrete model and the wooden trough. Furthermore, the models were made to overturn by the application of a concentrated load at the center of gravity of the dam—that is, along its line of symmetry—while water pressure acts uniformly over the entire area of the up-stream face. The difference in the structural action resulting from the two kinds of loading is obvious. The concentrated load tends to overturn the dam by direct action at the center, while the free wings do not undergo any deformation. They simply tend to rotate about the heel of the central part of the dam. The uniform water load, on the other hand, affects the central part mostly by indirect action through the shearing stresses developed between the wings and that part, after the primary deformation of the wings has occurred down stream.

Professor Lambert is to be commended for having called attention to the different effects of arching gravity dams up stream and down stream with a view to analyzing the stress conditions in existing gravity dams located in comparatively narrow canyons. The problem as outlined, however, should not prove very important, because if the canyon is comparatively large the use of a straight gravity dam will be indicated in preference to an arched form, and if an arched gravity dam is used in a wide canyon the advantages claimed by the author are relatively insignificant due to the comparatively insignificant maximum of the wings when compared with the maximum of the central part; in fact, the shifting of the center of gravity that occurs as the result of the customary moderate arching is extremely small, regardless of which way the dam is arched, and the structural deformations that take place in a dam arched up stream will compensate entirely for such a shift.

If, on the other hand, the canyon is comparatively narrow, as in the model experiments described by Professor Lambert, the advantages of a true arched dam will outweigh those of an arched gravity dam; that is, such a site dictates the use of a structure in which the cantilever loading may be decreased liberally and the arch loading increased in proportion, by reducing the exaggerated dimensions in the lower regions of the dam such as are necessary for gravity dams either straight or slightly arched. Hence, the straight dam, or the dam arched down stream, will not be feasible. In any case, in true arched dams the position of the center of gravity has no appreciable influence on the stability of the structure.

Briefly, Professor Lambert's suggestions are valuable as applied to gravity dams located in comparatively narrow canyons; but, for such locations, gravity dam sections should not be selected.

William P. Creager,[5] M. Am. Soc. C. E. (by letter).—The statements contained in the author's paper are interesting and correct, based on monolithic structures such as those used in his experiments. However, for a full-sized dam split by transverse expansion cracks or joints, it is not possible to transfer, by shear or cantilever action, the weight of the extreme ends of the dam to the central portion. In other words, whether the dam is arched up stream or down stream, each radial section must be designed independently of the others, unless, of course, in the usual type of arched gravity dam, the radius is sufficiently small to allow consideration of arch action.

---

[5] Chf. Engr., The Power Corporation of New York, Buffalo, N. Y.

In the case of a straight dam, correct practice would not allow the use of width of base at the highest part, as applying to the entire structure, in the determination of stability. The theory is no different whether the dam is arched up stream or down stream.

The author points out correctly that, for a parallel-sided site, the ends are more stable if the dam is arched down stream. This is particularly true as regards sliding, because a radial section would be required to slide up-hill. This feature, in the writer's opinion, is the only one in favor of arching the dam down stream as compared either with a straight dam or a dam arched up stream. It is believed that it is not a sufficiently desirable feature to warrant using more concrete as compared with a straight dam or voiding the possible feature of ultimate arch action before absolute failure as compared with a dam arched up stream.

In Fig. 2, the author suggests a novel steel suspension type of dam. It is assumed that this illustration is diagrammatic and that the suspension bars would actually be curved to the radius of the arch to avoid one enormous single jack. It would be interesting to know the cost of adequate anchorages for the suspension bars; it occurs to the writer that they would be quite expensive.

T. L. E. Haug,[6] M. Am. Soc. C. E. (by letter).—The author's treatment of this subject is notable for its recognition of the importance of considering the dam as a unit, rather than as merely an assemblage of thin slices or elements, of which it has been thought sufficient to treat only one as typical of the whole structure.

The results of experiments on models must be interpreted with great care because, unless the model exactly reproduces all the conditions obtaining in the full-sized structure, unwarranted conclusions may be drawn.

Professor Lambert states that the overturning load applied to each of his models was a single horizontal force at the theoretical center of pressure. In an actual dam the conditions are quite different, the water pressure being distributed over the entire up-stream face.

If the wings of an actual gravity dam are to transmit overturning loads to the central portion, they must undergo an appreciable down-stream deflection relatively to that central portion. When the wings are keyed into the canyon sides, they are thereby prevented from taking such a deflection. In other words, the wing foundations absorb the wing loads before they can be transmitted to the central portion of the structure.

As a matter of fact, since the central part of a dam is usually the greatest distance above the foundation, the crest deflection in the center, due to water load, is usually greater than that of the wings, so that part of the load on the central portion would tend to be transferred to the wings, rather than the reverse. This load transfer would be by trans-canyon beam action, which is considerably modified by the presence of contraction joints, with possibly some arch action.

---

[6] South Berkeley, Calif.

Contraction joints would prevent the dam curved down stream from acting as a unit, and the stabilizing moment computed on the basis of monolithic action would not be realized. The greater deflection of the central portion under load would tend to pull it down streamward away from the wings, thus preventing monolithic action; and it would be unsafe to attribute to such a structure greater stability than that of a straight dam having the same cross-section.

Professor Lambert's reference to the causes of failure of the St. Francis Dam appear to be well taken. In this case the water pressures on the wings actually were transmitted to the central portion, but only because the defective foundations of the wings permitted this to occur by allowing the prerequisite down-stream deflections to take place. In such a case, it is easy to show mathematically that the toe stresses in the central portion can approach the ultimate strength of the material and cause spalling, such as actually occurred in the St. Francis Dam. The central portion of the dam barely escaped being carried away; it was relieved of the extra load which caused the toe to spall off, by the breaking off of the wings. According to the writer's computations, if the dam had been straight, the central toe stresses, while high, would have been insufficient to cause spalling.

The author's clean-cut presentation of this subject demonstrates the importance of a more critical examination of these structures than they sometimes receive, especially as regards the effects of foundation conditions on stability and stress.

B. F. Jakobsen,[7] Esq. (by letter).—The experimental investigations reported by the author are interesting and illustrative, and to many engineers, no doubt, more satisfactory than purely theoretical investigations. The experimental investigations are based on the dam as a continuous whole, and the results are just what theory leads one to expect. The writer considered the effect of arching a gravity dam some years ago, treating the dam as a whole, and concluded[8] that,

> "Arching in this case, therefore, means that a definite disadvantage, the reduction in stability, is exchanged for a very problematical gain due to arch action."

When a thin slice of dam is considered, as in the customary analysis, it can be readily shown that arching decreases the gravity action.[9] P. Wilhelm Werner, Assoc. M. Am. Soc. C. E., has shown the increase in stability which is obtained when the gravity dam is arched down stream instead of up stream, as is usual.[10] He applies his formulas to the Exchequer Dam and compares the stresses found with those in the dam as built, arched up stream.

---

[10] *Transactions*, Am. Soc. C. E., Vol. 92 (1928), p. 784.

When considering the dam as a whole, it is necessary, as the author points out, to bear in mind that shrinkage cracks or planes of weakness may exist, so that the dam, in fact, can not act as a whole. This might be overcome, of course, by constructing proper contraction joints, or by grouting, or by both methods. When a dam rotates on its toe, it is difficult to determine with any degree of precision what the stresses are at the contact between the toe and the foundation. This would depend on the load to be carried by the toe and on the deformations of the concrete and the rock. In the case of the St. Francis Dam there were evidently definite planes of weakness, more or less vertical and radial, so that the dam did not act as a whole; and, furthermore, there appears to have been spawling at the toe of the maximum section. On the whole the safer design will generally result when thin sections of a dam are considered. The only exception to this may be where the height of the dam changes rapidly, so that the longer cantilevers lean upon the shorter, as the writer has discussed elsewhere.[11] Small dams might conceivably be considered as a whole, especially if the abutments are not too steep.

The writer does not look with favor on Professor Lambert's suggestion of anchoring the dam by steel tension members. It might be useful and acceptable where the rock is especially good and free from fractures and for a more or less temporary structure.

The tests are a welcome addition to engineering literature, and it is gratifying to see that they agree so well with theoretical deductions.

A. Floris,[12] Esq. (by letter).—In this paper the author attempts to investigate the statical behavior of gravity dams in relation to the topography of the site. This method seems to be quite logical. However, it requires that the structure be analyzed as a whole instead of by the customary practice of considering vertical slices only. This last simplification is made for the purpose of facilitating the stress analysis of gravity dams; but, nevertheless, an exact stress determination with regard to the foundation conditions of the dam is not yet available. .

By proposing to consider the entire dam as acting in one piece, the author introduces additional difficulties which render even an approximate analysis of gravity dams very difficult. He restricts himself to the study of overturning movements of concrete dam models with special reference to their site, but his observations are not expressed in a precise mathematical form. In the paper, general methods are not given by which the limiting cases can be ascertained and thus the place at which the dam begins to overturn, or at which failure begins to occur due to excessive stresses, cannot be determined.

In a rather unsatisfactory manner Professor Lambert considers equilibrium conditions only, as if he was dealing with perfectly unelastic bodies. How great are the stresses and how are they distributed under the influence of the weight of the dam and the water pressure before overturning? These questions are not answered satisfactorily. Those who advocate innovations in the design and analysis of structures, must follow their ideas to the end and solve the problem completely. The study of the stability of dams by the aid of relatively large models, as suggested by Professor Lambert, are of no value, if an adequate theory of the relation between dam and site is lacking.

[12] Civ. Engr., Los Angeles, Calif.

A fair comparison between dams curved up stream and those curved down stream can be made, if the structure is considered purely as a gravity dam. Otherwise, the dam curved down stream is decidedly at a disadvantage over the one curved up stream. As dams are made from concrete, a material of low tensile strength, it follows that the ones curved down stream (which are cylinders subjected mostly to tension) are inferior to those curved up stream, stressed mainly by compression. The latter are only arches and, therefore, the author's usage of the expression, "gravity dams arched down stream," is somewhat misleading.

The standing section of the St. Francis Dam does not bear testimony in favor of either the down-stream or the up-stream forms. It indicates merely that in dams with a great radius of curvature in plan, gravity action only can be relied upon. Apparently, in the central part of the St. Francis Dam, the foundation conditions were better than in the two wings. This fact was stressed in the various reports on the failure of this dam.[13]

The suggested use of chains for the purpose of preventing gravity dams from overturning and sliding, is quite unusual and, it may be said, out of the question from purely practical considerations. Gravity dams with their great quantity of concrete, implying strength and durability, are incompatible with thin steel chains having a restricted life of usefulness. From the theoretical point of view these chains complicate the stress analysis of gravity dams, which is a fact overlooked by Professor Lambert.

As far as the writer knows, gravity dams curved down stream were first suggested[14] by P. Wilhelm Werner, Assoc. M. Am. Soc. C. E.

Floyd A. Nagler,[15] M. Am. Soc. C. E. (by letter).—The question raised by Professor Lambert with regard to the arching of gravity dams, is quite valid for dams built between narrow canyon walls with the abutments parallel to the canyon wall itself. However, the abutments of such dams would generally be seated into the canyon wall, and the dam would no longer act strictly as a gravity dam. In all such cases it would be preferable to arch the dam up stream rather than down stream, in spite of the considerations to the contrary for the true gravity type, which have been presented by the author.

Regardless of the fact that gravity dams are generally analyzed in linear-foot sections one should never fail to consider the behavior of the dam as a whole. This has received too meager emphasis in most textbooks, although it is casually mentioned by some authors. Some engineers assert that a large dam does not act as a unit, as assumed by the author, but one must answer the question as to how large a dam must be before it will fail to do so. The small models described by Professor Lambert certainly acted as a unit, and if large dams do not do so, somewhere in the range of size of masonry dams, there must be a structure so large that no shearing stress exists between adjoining sections. This is absurd. Many gravity dams known to the writer still stand because they are acting as monoliths, whereas erosion has so seriously undercut certain sections that if considered by themselves they should have failed long ago. The evidence disclosed by the St. Francis Dam disaster indicates that the shearing stress between adjacent sections of the dam must have been exceedingly great. Although gravity dams have numerous construction and expansion joints, interlocking generally exists so that the dam can function more or less as a unit. Hence, the author's contentions should stimulate serious consideration.

[14] *Transactions*, Am. Soc. C. E., Vol. 92 (1928), p. 784.

[15] Prof., Hydr. Eng., Univ. of Iowa, Iowa City, Iowa.

B. J. Lambert,[16] M. Am. Soc. C. E. (by letter).—The writer would like to make it clear that he believes that a gravity dam arched down stream can be used only in a canyon having particular features as to width of canyon, slope of walls, and height of dam. This might occur only once in a hundred or more locations, so the discussion is more or less academic. This scheme would be ridiculous if it were applied to the average canyon dam, regardless of the factors mentioned.

There also seems to be a difference of opinion as to the size of dam that ceases to act as a unit and begins to act in sections. It is true that English-speaking engineers have become accustomed, in using the pressure formula, $\frac{wh^2}{2}$, to define w as pounds per cubic foot of water and h, in feet, thus implying slices 1 ft. in width; but in the metric system, as used in France, Germany, Spain, etc., the terms, w and h, are based on the meter, in which the volume is about thirty-five times as great as that based on the foot. It is not unreasonable to suppose that the "Brobdingnagians" used a linear unit equal to ten or even one hundred times that of American units, with a corresponding volume equal to 1 000 to 1 000 000 cu. ft.

It would seem almost obvious that the sizes of the blocks into which a dam might break is a function of the thickness of the dam. If the average thickness is a few inches or a few feet, the sizes of the blocks might well be a few cubic inches or a few cubic feet; but when dealing with dams several hundred feet thick it seems reasonable to assume that the blocks or units that might be considered, would be of a much larger volume.

Where the back of a dam is constantly covered with water to a greater or less extent, the temperature changes may not be extreme through a large portion of the structure, so that the breaking into blocks is more or less limited by the shrinkage incident to the setting up of the concrete. If these contractions are under fair control, as will be attempted in the Hoover Dam, it is reasonable to suggest that possibly this dam can act practically as a unit, since it will have a maximum thickness of 650 ft., with an average of, say, 300 ft., or more, an average length of about 500 ft., and a maximum height of approximately 650 ft. If this huge plug of concrete were constructed in a canyon with smooth sloping walls, as shown in Fig. 2(a), there would be little doubt in the writer's mind, that the stresses on the smaller length of toe would be much in excess of those computed by the ordinary slice method. However, when one considers that, in practice, the sloping walls are roughened and also made more or less normal to the radius of the arch plan, then these modified conditions make the problem so complex that even an approximately exact analysis is impossible.

---

[16] Head, Dept., Civ. Eng., State Univ. of Iowa, Iowa City, Iowa.

It is not difficult to imagine various things that might be occurring in a structure where such immense masses, pressures, and uncertain conditions are involved, therefore, in presenting this brief paper, it was the writer's intention to set out merely another point of view, the merits of which may be dependent on many debatable factors.

FLOW OF GROUND-WATER AS APPLIED TO DRAINAGE WELLS[1]

BY M. R. LEWIS,[2] M. AM. SOC. C. E.

WITH DISCUSSION BY MESSRS. L. STANDISH HALL, O. W. ISRAELSEN, AND M. R. LEWIS.

SYNOPSIS

Much study has been given to the capacity of wells to furnish water and oil, and, with the use of deep wells for the drainage of irrigated lands, the shape and extent of the cone of depression become of great importance.

In this paper three types of wells are discussed: (*A*) Artesian wells (not necessarily flowing), with a perforated casing extending through the water-bearing stratum; (*B*) wells in which the water-table is in the water-bearing stratum and which penetrate its full depth; and (*C*) open-bottom wells, that is, wells which just reach the water-bearing stratum.

Cases in which the zone of influence is either definite or indefinite are considered for each type; and formulas for the draw-down curves of each of these types of wells are derived.

The conclusion is drawn that if the area to be drained is more than a few hundred feet in diameter, successful drainage will depend on a general lowering of the water-table.

To secure this lowering, wells should be designed to have the greatest possible capacity with an economical lift. Such capacity may be secured most readily, where conditions are favorable, by deep wells.

INTRODUCTION

Much study has been given to the theory of the flow of ground-water and oil into wells. Practically all this study has been directed toward estimating the quantity of water or oil which might be secured from wells under conditions differing as to diameter and depth, thickness and character of water-bearing strata, and depth of draw-down. Since wells and deep-well pumps have been used for the drainage of irrigated lands, the shape and extent of the draw-down curve or cone of depression have become of primary importance.

---

[1] Published in March, 1931, *Proceedings*.

[2] Irrig. and Drainage Specialist, Oregon State Coll., and Div. of Agri. Eng., U. S. Dept. of Agriculture, Corvallis, Ore.

It is difficult, if not impossible, to determine by field studies and laboratory tests the exact capacity for the transmission of water of the water-bearing strata in any given case. In spite of this fact, however, it is well worth while to consider the effect on the draw-down curve of changes in the various controlling factors under certain assumed conditions.

The first assumption which is made in such studies is that the water-bearing strata are uniform. This will be approximately true in most cases, but far from correct in others. Since the variations in this regard may be infinite in number, and are impossible of determination, it does not seem worth while to attempt a discussion of such cases.

A second assumption, which is applied in the case of those wells that penetrate the full depth of the water-bearing stratum, is that the water pressure is transmitted without hindrance in a vertical direction and that it corresponds to static pressure in any given vertical line; in other words, that the water would rise to the same level in each of a series of piezometer tubes open to the ground-water at various elevations below the water-table in the same vertical. This assumption is probably true in regard to artesian wells that extend through a water-bearing stratum, when the retaining beds are impervious. When the water-table is in the water-bearing stratum, the lines of flow will not be horizontal, and the second assumption is not correct. However, only in the case of wells in which the draw-down is large as compared with the depth of the water-bearing strata—and even then only near the well where the slope of the water-table is great—will the error be appreciable.

In this paper the piezometric surface and water-table are assumed to be level before pumping commences. From this assumption it follows that there is no flow of the ground-water except to the well.

In the case of the drainage wells designated herein by the secondary letter, *b*, the assumption that the quantity of water reaching the water-table is uniform per unit of land area, seems to require either that the well under consideration is in the interior of a homogeneous group of wells the zones of influence of which are contiguous, or that the water-table at the boundary of the zone of influence is at the surface of the ground.

It is evident that these assumptions in themselves limit the rigorous application of the formulas to very special cases. An exact application of the laws of hydrodynamics would require consideration of the effect of inertia and of the probable inapplicability of the Darcy law to extremely high velocities. The writer has made no attempt to do this. It is believed, on the other hand, that the general relationship between the variables considered are correctly presented and have rather wide application.

The fact that the cost of power is a controlling factor in irrigation pumping makes the total extent of the draw-down in irrigation wells a matter of first consideration. In the case of drainage wells, the extent of the draw-down at the wells and throughout the drained area is of primary importance. The cost of power (except for variations in demand charges, pump and motor efficiencies, and friction losses in the piping) is proportional to the total height through which water must be lifted. This total lift is made up of the distance the water must be lifted above the static water-table, plus the total draw-down.

The former is fixed by the topography and other considerations, but is not affected by changes in the well. The total draw-down is made up of the friction in the well tube between the point where the water enters the well and the entrance to the suction pipe of the pump, plus the loss of head at the perforated well-casing or strainer, if one is used, or the entrance head into the well tube, plus the loss of head through the water-bearing strata. Under normal conditions the last item is by far the largest part of the total draw-down and is the only part considered herein. The loss of head at the strainer is known to have been an important factor in many instances.

The shape of the draw-down curve will depend on the size and character of the well and on its relation to the water-bearing strata and the source of water supply. Theoretical formulas and curves for three types of wells are given herein. For each type the effect of a local or distant water supply is taken up. Furthermore, the effect of changes in the character and thickness of the water-bearing strata, of the diameter and depth of the well, and of the quantity of water pumped, is illustrated.

NOTATION

In addition to the symbols, defined by diagrams in Figs. 1, 4 and 6, the following notation is adopted for use in this paper and its discussion:

C = a constant.
d = diameter of sand particles, in millimeters.
k = transmission coefficient in water-bearing strata.
k_1 = transmission coefficient in relatively impervious overlying stratum.
K = a factor that varies with the porosity of the material.
Q = quantity of water passing concentric surfaces of radius, r.
Q_1 = the discharge of the well.
V = velocity of a stream of water.
w = the rate of downward percolation.

In order to facilitate reference, various types of wells are identified by symbols in the paper. Briefly, the definitions of these symbols are, as follows:

Type *Aa* is an artesian well with a perforated casing that extends through the water-bearing stratum. This stratum is assumed to lie between two impervious retaining beds and contains water under such hydrostatic pressure that the water level just outside the casing will not be lowered, by pumping, below the upper edge of the stratum.

Type *Ab* is an artesian well with a perforated casing that extends through the water-bearing stratum. In this case the overlying stratum is only relatively impervious and the supply to the well is derived by vertical flow, or percolation.

Type *B* consists of wells in which the water-table is in the water-bearing stratum and which penetrate the full depth of the stratum.

Type *C* is an open-bottom well which just reaches the water-bearing stratum.

The relations between Types *Ba* and *Bb* and between Types *Ca* and *Cb* are similar to that between Types *Aa* and *Ab*.

TYPE *A*.—ARTESIAN WELLS EXTENDING THROUGH WATER-BEARING STRATUM

The case of the simplest well (Type *Aa*) has been discussed by Slichter,[3] Turneaure,[4] and others. It is that of a well penetrating the full depth of a water-bearing stratum lying between two relatively impervious retaining beds and containing water under such hydrostatic pressure that the water level in the well, or rather just outside the well-casing, will not be lowered, by pumping, below the upper edge of the water-bearing stratum. In each case these writers have assumed that all the water came into the stratum from outside the zone of influence of the well. Under such conditions, the curve of the modified piezometric surface would rise indefinitely, but at a decreasing rate, as the distance from the well is increased. The water flowing toward the well will pass through concentric cylindrical surfaces in the water-bearing stratum, having areas of $2 \pi D r$ (for notation, see Fig. 1). The velocity of flow according to the well-known law of Darcy will be proportional to the slope of the hydraulic gradient. For convenience, the transmission coefficient, *k,* used by Slichter,[3] and defined as the quantity of water passed in unit time by a prism of the material of unit cross-sectional area and unit length under the pressure of a column of water of unit height—using as units, the foot and the minute—has been adopted for this paper. The velocity of a hypothetical stream of water occupying the full area of the cross-section at any distance from the well is, therefore,

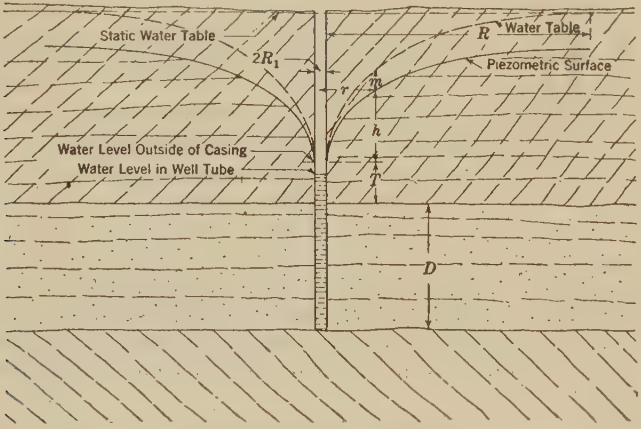

FIG. 1.—TYPE *A* WELL.

$$V = k \frac{dh}{dr} \dots\dots\dots\dots\dots\dots\dots\dots (1)$$

The quantity, *Q,* flowing toward the well, is equal to the discharge of the well, Q_1, and is constant for all values of *r;* therefore,

$$Q = Q_1 = 2 \pi D r k \frac{dh}{dr} \dots\dots\dots\dots\dots\dots (2)$$

---

[4] "Public Water Supplies", by F. E. Turneaure and H. L. Russell, Third Edition, p. 262, John Wiley & Sons, New York, 1927.

Integrating,

$$h = \frac{Q_1}{2\,\pi\,D\,k}\log_e r + C \ldots\ldots\ldots\ldots\ldots\ldots\ldots (3)$$

When $r = R_1$, $h = 0$; and if $R_1 = 1$, $C = 0$. If R_1 has any other value, C will vary with changes in the values of the other constants.

On Fig. 2 the draw-down curves for certain assumed values of Q_1, D, R_1, and k are shown.

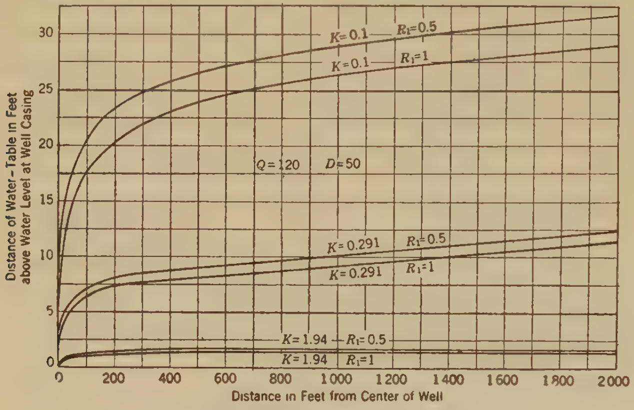

FIG. 2.—DRAW-DOWN CURVES FOR TYPE *Aa* WELLS.

Type Ab.—Where wells are used for the drainage of irrigated lands during the irrigation season, or of humid lands during rainy seasons, the conditions are modified to the extent that the water supply does not come along horizontal planes from an indefinite distance, but downward from the soil overlying the cone of depression.

When a well is first put into operation the water withdrawn from the cone of depression will most probably reach the water-bearing stratum at a greater rate per unit of land area near the well than at a greater distance. After the water-table has been lowered to an equilibrium position the supply will come entirely from the surface. The rate of downward percolation in practically all cases will be governed by surface conditions and will be substantially independent of the draw-down. For this reason a uniform rate is assumed.

If w is the rate of downward percolation, in cubic feet per minute per square foot of horizontal area, the conditions are expressed by the following formulas:

$$Q = Q_1 - w\,\pi\,r^2 \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (4)$$

in which, Q_1 is the discharge of the well and Q, the variable quantity passing the concentric cylindrical surfaces of the radius, r. Substituting for Q in Equation (4), its equivalent in Equation (2):

$$Q_1 = 2\,\pi\,D\,r\,k\,\frac{dh}{dr} + w\,\pi\,r$$

$$Q_1\,dr = 2\,\pi\,D\,r\,k\,dh + w\,\pi\,r^2\,dr$$

$$dh = \frac{Q_1}{2\,\pi\,D\,r\,k}\,dr - \frac{w\,r}{2\,D\,k}\,dr$$

and,

$$h = \frac{Q_1}{2\,\pi\,D\,k}\log_e r - \frac{w}{4\,D\,k}\,r^2 + C \ldots\ldots\ldots\ldots\ldots (5)$$

If w is assumed as any probable value; as, for example, 0.000017 (3.67 ft. in depth over the surface in 150 days), and if $R_1 = 1$ ft., the value of C will be practically zero. With other values of R_1, C will be the same in this case as in the one preceding. It will be noted that the factor, w, is somewhat analogous to the transmission coefficient, k. Its value is so small compared to the common values of k that ordinarily there will be no inconsistency in the assumption that the percolating water moves downward through the relatively impervious stratum. The zone of influence of the well in this case will be governed by the values of w and Q_1 in the following relation:

$$Q_1 = w\,\pi\,R^2 \ldots\ldots\ldots\ldots\ldots\ldots\ldots (6)$$

in which, R equals the radius of the zone of influence.

The water-table will stand above the piezometric surface, as both are depressed by pumping, because of the head required to force the water downward through the upper stratum. The movement will not be in an exactly vertical direction as long as the piezometric surface slopes toward the well. However, as the upper stratum is relatively much more impervious than the lower one, vertical flow may be assumed without serious error, except very close to the well where the slope of the water-table is extremely steep. Let k_1 represent the transmission coefficient for the overlying stratum; m, the height of the water-table above the piezometric surface; and T, the thickness of the more impervious material below the level of the piezometric surface at the well. Under these conditions the following formulas will hold:

$$w = \frac{m}{m + h + T}\,k_1 \ldots\ldots\ldots\ldots\ldots\ldots\ldots (7)$$

$$m = \frac{h + T}{\frac{k_1}{w} - 1} \ldots\ldots\ldots\ldots\ldots\ldots\ldots (8)$$

and,

$$m + h = \frac{h\,k_1}{k_1 - w} + \frac{w\,T}{k_1 - w} \ldots\ldots\ldots\ldots\ldots (9)$$

Substituting in Equation (9) the value of h given in Equation (5),

$$m + h = \left(\frac{Q_1}{2\,\pi\,D\,k}\log_e r - \frac{w\,r^2}{4\,D\,k} + C\right)\frac{k_1}{k_1 - w} + \frac{w\,T}{k_1 - w} \ldots\ldots (10)$$

Equations (5) and (10) will hold only for values of r equal to, or less than, R. (See Fig. 3 for typical results.)

TYPE *B*.—WELLS IN WHICH WATER-TABLE IS IN WATER-BEARING STRATUM

Another common case (Type *Ba*) is illustrated in Fig. 4. The water-table, both under the static condition and during pumping, lies wholly within the water-bearing stratum. Turneaure[4] has shown that the formula for the draw-down curve in this case is (adopting the notation used herein and shown in Fig. 4):

$$h^2 = \frac{Q_1}{\pi\ k} \log_e r + C \ldots\ldots\ldots\ldots\ldots\ldots\ldots (11)$$

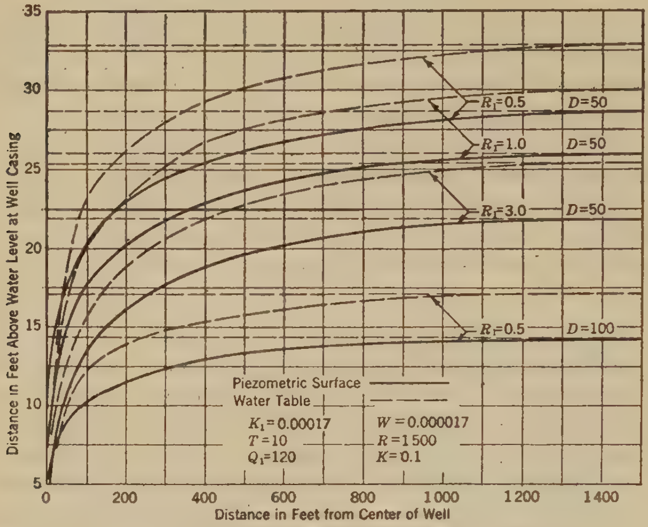

FIG. 3.—DRAW-DOWN CURVES FOR TYPE *Ab* WELLS.

In Equation (11), when $r = R_1$, $h = D$; and, if $r = R_1 = 1$, then $C = D^2$. Here, again, the value of C will vary with the other factors if R_1 does not equal 1.

Type Bb.—In the more typical case of drainage wells, where the water supply comes from the surface above the cone of depression:

$$h^2 = \frac{Q_1}{\pi\ k} \log_e r - \frac{w\ r^2}{2\ k} + C \ldots\ldots\ldots\ldots\ldots\ldots (12)$$

Again, when $r = R_1$, $h = D$; and if $r = R_1 = 1$, the second term on the right of the equation is practically zero and $C = D^2$. Fig. 5 shows some typical draw-down curves for this case.

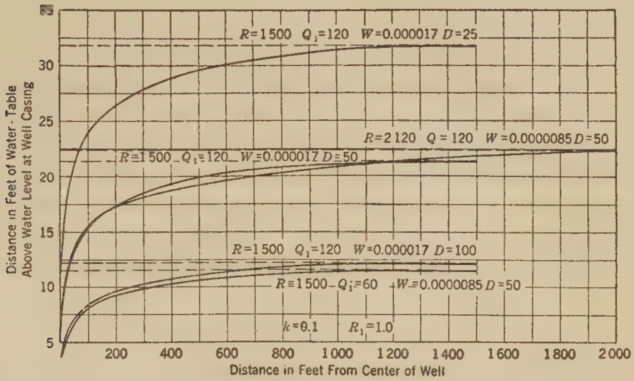

Fig. 5.—Draw-Down Curves for Type *Bb* Wells.

Type *C*.—Open-Bottom Wells Driven Just to the Water-Bearing Stratum

A third type of well (Type *Ca*) is illustrated in Fig. 6. This class includes wells which are drilled through a consolidated stratum to tap an artesian flow in a water-bearing stratum of sand or gravel. It is usual in developing wells of this type to pump out more or less sand. If the overlying bed is strong enough to stand up, the resulting cavity in the sand below will be cone-shaped with the point downward. The slope of the sides will be that of the angle of repose of the material when supersaturated with water. Observation of sand which is discharging water when excavated below the water-table indicates that the slope is about 1 on 12. This cavity will increase in size until the velocity of the water leaving the surface of the sand is just

insufficient to lift the finer particles. In a mixed material the finer particles will be washed out, leaving the cavity lined with the coarser particles. For this reason it is not necessary in all cases to excavate a shaft of large diameter to secure the maximum efficiency of this type of well. The velocity required to lift a particle of sand will vary, of course, with the size of the particle.

It is not necessary that the velocity of the water in the cavity just above the sand be great enough to carry the sand particles vertically upward. The bubbling up of sand in a spring shows the action which takes place. Richards,[5] in studying ore-classifying machinery, determined the velocity of the rising streams which would hold quartz particles of various sizes in full "teeter". This condition is somewhat similar to that which takes place in wells or springs. By plotting them on logarithmic paper his data are found to be represented with reasonable accuracy by the following formulas:

For particles 1.25 to 7.0 mm. in diameter:

$$V = 5.5\, d^{0.75} \qquad (13)$$

For particles 0.25 to 1.25 mm. in diameter:

$$V = 5.1\, d^{1.15} \qquad (14)$$

in which, V equals the velocity of the rising stream, in feet per minute, and d is the diameter of the quartz particles, in millimeters.

The radius, b, in feet, of the cavity in the sand stratum for the two grades of sand will then be as follows:

For particles of 1.25 to 7.0 mm.:

$$b = \frac{Q_1^{\ 0.5}}{4.16\, d^{0.38}} \qquad (15)$$

For particles of 0.25 to 1.25 mm.:

$$b = \frac{Q_1^{\ 0.5}}{4.01\, d^{0.58}} \qquad (16)$$

Whenever the water-bearing material is made up of sands of various sizes, the finer materials will be removed entirely, and the size of the cavity will undoubtedly depend on the proportion of fine material. It is probable that the condition assumed herein, of uniform-sized particles, will be the most unfavorable for the development of large flows of water.

For the purpose of this paper it will be sufficiently accurate to assume that the cavity is hemi-spherical in shape and has the same superficial area as the cone. The radius, R_2, of this hypothetical cavity will be 0.716 b. In this case the water approaching the well may be assumed to pass hemi-spherical surfaces having areas of $2\,\pi\, r^2$. Following the same procedure as in the case of wells of other types,

$$Q = Q_1 = 2\,\pi\, r^2 k\, \frac{dh}{dr} \qquad (17)$$

and,

$$h = -\frac{Q_1}{2\,\pi\, k\, r} + C \qquad (18)$$

---

[5] "Development of Hindred-Settling Apparatus", by Robert H. Richards, *Transactions*, Am. Inst. Min. and Met. Engrs., Vol. 41, p. 425, 1910.

If $r = R_2$, $h = 0$,

$$C = \frac{Q_1}{2 \pi k R_2} \qquad (19)$$

Equation (18) will hold only if the water-bearing stratum is of very great depth. If this stratum is of moderate depth, an approximate solution may be reached by using Equation (18) for values of r between 0 and D and Equation (3) for values of r greater than D.

Type Cb.—For the drainage well there will again be an approximation if the term is subtracted that accounts for water reaching the water-table from the surface; thus,

$$Q = Q_1 - w \pi r^2$$

$$Q_1 = 2 \pi r^2 k \frac{dh}{dr} + w \pi r^2$$

$$dh = \frac{Q_1}{2 \pi k r^2} dr - \frac{w}{2 k} dr$$

and,

$$h = - \frac{Q_1}{2 \pi k r} - \frac{w r}{2 k} + C \qquad (20)$$

Again, the second term on the right is negligible for small values of r and practically so for all values.

The same relation between the piezometric surface and the water-table holds in this case as in that of wells of Type *Ab*. (See Fig. 7 for typical curves.) The height of the water-table will be:

$$m + h = \left(- \frac{Q_1}{2 \pi k r} - \frac{w r}{2 k} + C\right) \frac{k_1}{k_1 - w} + \frac{w T}{k_1 - w} \qquad (21)$$

Another type of well which has been used in some faint-hearted attempts at drainage, and one that is fairly common in the irrigation field, is the dug well which just reaches into the water-table and is pumped to its utmost capacity. The draw-down curves for wells of this type would be quite similar to those of large diameter wells of Type *C*. The flow of water through the stratum above the level of the bottom of the well would tend, of course, to make the curve flatten out faster as r is increased.

PERMEABILITY OF WATER-BEARING STRATA

Many experimenters have worked on the problem of the rate at which soils, sands, and gravels will transmit water. Much of this study has been directed toward establishing some formula which would make possible the accurate prediction of permeability from an analysis of the physical characteristics of the material. Thus far no formula satisfactory over a wide range of materials and conditions has been found. The one devised by Slichter[6] is probably as satisfactory as any. It is as follows:

$$k = (1.1846) \frac{d^2}{K} \qquad (22)$$

---

[6] "Theoretical Investigation of the Motion of Ground-Waters," U. S. Geological Survey, Nineteenth Annual Rept., Pt. 2, p. 322, Wash., 1899; "The Motions of Underground Waters", U. S. Geological Survey, *Water Supply Paper 67*, Wash., 1902; "Field Measurements of the Rate of Movement of Underground Water", U. S. Geological Survey, *Water Supply Paper 140*, Wash., 1905.

in which, k is the transmission coefficient, in cubic feet per minute, per square foot of cross-section, per foot of head, through a column, 1 ft. long. The number, (1.1846), is the common logarithm of a constant factor or coefficient. Factor K varies with the porosity of the material. Equation (21) was used to determine the value of k corresponding to the given effective sizes and porosities in the computations for wells of Type C.

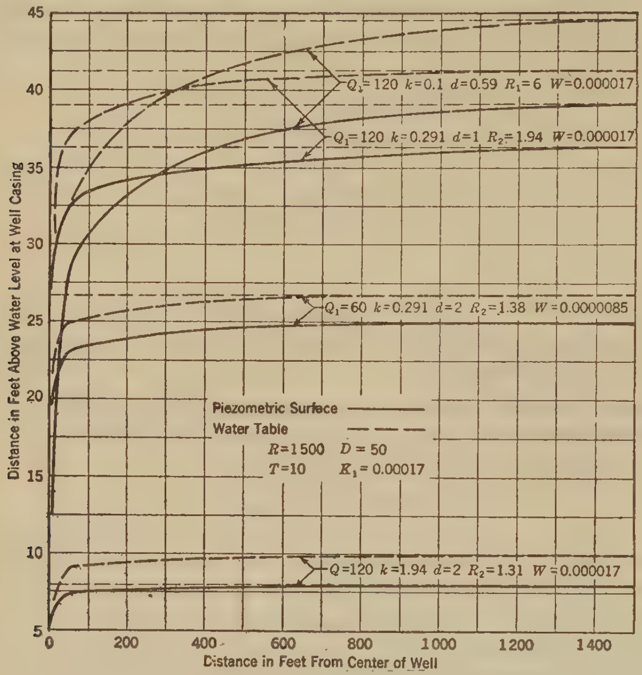

FIG. 7.—DRAW-DOWN CURVES FOR TYPE *Cb* WELLS.

Hazen,[7] Slichter,[6] Stearns,[8] and others, have given the results of experimental determinations of the rate of flow through sands and gravels. It is difficult to secure samples, for laboratory test, of unconsolidated material occurring near the surface in such a manner as not to disturb its structure and porosity. Such samples cannot be secured of the deeper-lying strata. In spite of this difficulty laboratory tests of the rate of flow seem to be much more satisfactory than the attempt to compute the rate from mechanical analyses.

Meinzer[9] refers to a method devised by Thiem, which appears to promise good results. In this method use is made of the slope of the water-table toward a well which is being pumped.

Application of Curves

The most obvious conclusion to be drawn from the curves and data shown herein is that satisfactory drainage by wells depends on the removal of sufficient water to lower the general ground-water level. This, of course, agrees with the general opinion of engineers engaged in the drainage of irrigated lands by open ditches and tile-drains. It will be noted that in none of the plotted curves in which the wells are taking all the water supplied to the ground-water in an area having a radius of 1 500 ft., is satisfactory drainage secured for more than 300 ft. from the well. In this statement "satisfactory drainage" is understood to mean a lowering of the water-table 5 ft., or more. In the case of a well discharging 360 cu. ft. per min., the radius of the circle with a 5-ft. lowering of the water-table is almost 800 ft., with a total draw-down of 31.4 ft.

Plotted curves from successful drainage wells bear out these results. Where such wells have accomplished satisfactory drainage over a considerable area there is evidence that the general level of the water-table has been affected. The plotted curves are very flat at and beyond the point where the water-table has been lowered sufficiently to provide adequate drainage. In some instances, local pot-holes may be drained by single wells which have little or no effect on the general level of the water-table.

It is evident that such a well should be designed so as to reduce the draw-down close to the well as much as possible and still maintain a sufficient depth to the water-table at the limits of the area to be drained. A comparatively shallow well appears to be most advantageous for this purpose. The quantity of water pumped must be sufficient to cause the required draw-down in the area to be drained.

Whenever that area has a radius of more than a few hundred feet, it would seem to be necessary to plan on a more or less general lowering of the water-table. To secure this effect, the wells should be designed on the basis of the maximum economic capacity.

Inspection of the formulas and of the resulting curves shows that in each class of wells the quantity of water delivered is proportional to the transmission coefficient. An increase in the depth of water-bearing strata penetrated is followed by a proportional increase of flow in Type *A* wells and deeper Type *B* wells. In shallow wells of the latter type the effect will depend on the relation between the depth of draw-down and the total depth of the well. In wells of Type *A* and Type *B* a change in the diameter of the well has a comparatively small effect on the capacity.

Note in Fig. 3 that the total draw-down of a given well, 1 ft. in diameter and penetrating 50 ft. of water-bearing strata, is 32.9 ft. Under otherwise similar conditions the draw-down of a well of six times the diameter penetrating the same depth of strata is 25.3 ft. (77% as great) while that of a well of the same diameter and penetrating twice the depth of water-bearing strata is only 17.0 ft. (52% as great). In wells of Type *C* it is obvious that as long as the cavity at the bottom of the well has a greater diameter than that of the well tube the latter will not affect the draw-down curve. In ordinary materials this means that the diameter of the well is not a factor unless it is very large. As shown in Fig. 8, open-bottom wells, even if of large diameter, will have a relatively great draw-down. These computations indicate that under uniform conditions the capacity of wells may be much more readily increased by increasing the depth of water-bearing strata penetrated than by increasing the diameter.

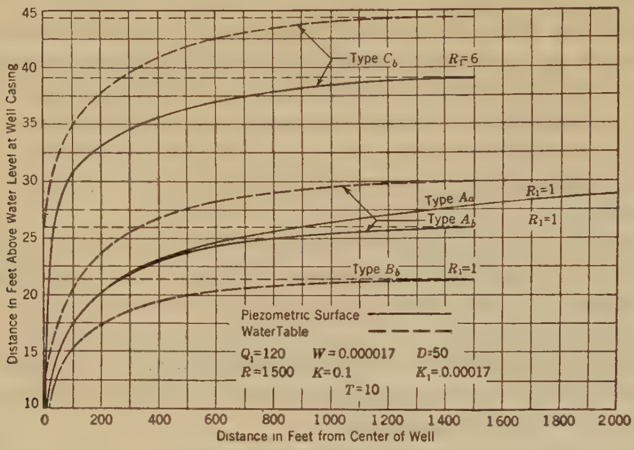

FIG. 8.—DRAW-DOWN CURVES.

When consideration is given to the fact that the strata lie normally in horizontal beds, the desirability of penetrating as deeply as possible into the zone of saturation, as long as the various water-bearing strata are interconnected, is emphasized.

ACKNOWLEDGMENTS

The author wishes to acknowledge the assistance of O. V. P. Stout, M. Am. Soc. C. E., in the preparation of this paper.

DISCUSSION

L. Standish Hall,[10] Assoc. M. Am. Soc. C. E. (by letter).—This paper is very timely as it offers a theoretical presentation of a subject for which real data are lacking to a large extent. It adds several formulas to the hydraulics of wells. The existing ones on this subject were unsatisfactory for general application since, as pointed out by the author, they covered only one or two special cases. The subject of the paper refers to drainage wells, but the formulas presented are of general application to wells, regardless of their use.

Although the formulas cover quite a range of cases, they are somewhat difficult of application in advance of the drilling and operation of a well, because of the difficulty in determining in advance the conditions which will be met. In fact, several other conditions relative to the flow of ground-water are possible in addition to those presented in the paper. For example, deep wells usually penetrate several water-bearing strata, the transmission coefficients of which are, in many cases, different for each stratum penetrated by the well. The Type *A* wells may penetrate several strata with downward percolation to some of the pervious beds and with no downward percolation to the remainder of the beds. A well may also belong to the Type *B* in the upper strata and to the Type *A* in the strata penetrated at greater depth. In pumping wells of this last type, the water level in the well during pumping may be drawn below the bottom of the upper strata, allowing a free discharge into the well from the strata thus exposed.

If a well should penetrate several minor water-bearing strata and be landed as an open-bottom well (Type *C*), a combination of this latter type with either Type *A* or Type *B* is possible. The formula presented by the author for the Type *C* well (Equation (20)), indicating a greater draw-down during pumping than for either the Type *A* or Type *B* well, as shown in Fig. 7, appears to be contrary to general opinion. The writer has made no actual measurements of the performance of these wells during pumping, but statements of owners indicate that the draw-down is usually small. A well not originally drilled as an open-bottom well may often evolve into this type at points where it penetrates unconsolidated strata, particularly if these strata are not cased off in the well. The writer has in mind an example of a well which was drilled originally to a depth of 194 ft. When it was first pumped, twelve wagon-loads of fine sand were discharged with the water. The present depth of the well is 141 ft., which is evidently the depth at which the main water-bearing strata were encountered. Soundings made with a 6-ft. iron rod indicated that a large cavity existed at this depth. The owner stated that pumping of the well did not lower the water level appreciably. Other similar instances could be cited.

With regard to the application of wells to the drainage of land—while they may furnish a large discharge, deep wells may not accomplish the purpose desired. The lands generally requiring drainage are at a low elevation and frequently receive the drainage from higher lands. If the deep wells penetrate sandy strata interbedded with impervious layers with the dip of the strata following the general ground slope, pumping may drain only strata outcropping on higher ground, particularly if the well is of the *A* type. Under this condition the pumping would lower only the piezometric surface and have very little effect in lowering the water-table in the territory requiring drainage.

---

[10] Chf. Hydrographer, East Bay Municipal Utility Dist., Oakland, Calif.

Even in cases where the deep wells penetrate pervious beds of sandy strata for their entire depth, they may be disadvantageous for the purposes of draining land. This is particularly true when wells that are being operated are considerable distances apart. In order to lower the water-table between the drainage wells, under these conditions, the water level in the vicinity of the well may have to be lowered excessively. This may result in the necessity of frequent irrigation of the lands near the wells, thereby partly defeating the purposes of drainage.

The shallow well that reaches just below the water-table and is pumped to its utmost capacity (which has been mentioned by the author) appears to be the most efficient for drainage. One difficulty presents itself in the case of the use of wells of this type. The yields of each individual unit may be small, thus requiring that they be spaced closely together. This necessitates many wells and the purchase of much pumping equipment, which in some cases may result in a prohibitive cost.

The use of drainage wells for lowering the water-table in the lower areas of irrigation projects is gaining in favor since it permits of the re-use of the water recovered by drainage, for irrigation of additional acreage. It also makes an irrigation system more flexible by providing an underground supply on which one may draw heavily during years of deficient surface run-off.

The subject presented by the author is one on which additional data need to be collected and available existing data need to be correlated.

O. W. ISRAELSEN,[11] M. AM. SOC. C. E. (by letter).—The study of flow of ground-water toward wells is not only of scientific interest, but also of real practical importance. Mr. Lewis is to be congratulated on the thorough and valuable analyses presented.

The term, transmission "constant," was used by Slichter, not transmission "coefficient." In defining the transmission constant or coefficient, care should be exercised to specify unit pressure head difference. That part of the author's definition ("Type of Wells") of the transmission coefficient which reads, "under the pressure of a column of water of unit height," is clearly incomplete.

In a paper entitled "The Drainage of Land Overlying Artesian Basins,"[12] by Messrs. Willard Gardner, W. W. McLaughlin, and the writer, an equation analogous to the author's Equation (3) was derived, namely:

$$h = \frac{Q_2}{\rho} \times \frac{\log_e \dfrac{r}{R_1}}{2\pi\, D g\, k_2} \quad\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (23)$$

---

[11] Prof., Irrig. and Drainage Eng., Utah State Agri. Coll., Logan, Utah.

[12] *Soil Science*, Vol. 26, No. 1 (1928).

in which, in addition to the author's notation:

Q_2 = mass of water per unit time.
ρ = density.
g = acceleration due to gravity.
$k_s = \frac{k}{g}$

The author's k has the physical dimensions of $\frac{L}{T}$. The symbol, k, is a transmission constant that has the physical dimensions of time; thus,

$$\frac{k}{g} = \frac{\frac{L}{T}}{\frac{L}{T^2}} = T.$$

In commenting on Equation (5) the author states that: "It will be noted that the factor, w, is somewhat analogous to the transmission coefficient, k." This statement could well be made more direct. As shown in Equation (7), w is proportional to the transmission coefficient of the overlying, relatively impervious material, k_1. The quantities, w, k, and k_1, are dimensionally the same.

Field studies of the cone of depression in the piezometric surface near the axis of the pump in an experimental drainage well in Utah, of the Type *Ab*, confirm in general the requirements of Equation (5).[13]

The author's Equations (10) and (21) and their applications are of special interest. It is important to note that for Type *Ab* wells "satisfactory drainage" at a given distance from a well is not only a function of h, but also of the transmission constant, k_1. Equation (8) shows that as k_1 increases, m decreases, for any given values of h, w, and T. Satisfactory drainage with the Type *b* wells is also dependent on the quantity of irrigation water applied, which influences the quantity, w.

Measurements of the piezometric surface, as influenced by pumping from a Type *Ab* well, in Utah, show significant reductions of pressure head at distances considerably more than 1 000 ft. In this case, it would seem that if k_1 were fairly large and m relatively small, satisfactory drainage may be secured at a distance from the well several times greater than 300 ft.

All the equations derived by the author, together with the diagrams illustrating their applications to typical cases, are of genuine interest to engineers who are concerned with pumping water from ground-water sources whether for drainage or for irrigation purposes.

The increasing "steepness" of the cone of depression of the piezometric surface as the axis of the well is approached, especially for water-bearing materials having a relatively low transmission coefficient, stresses the importance of research concerning design of wells with a view to flattening the cone economically and reducing the power requirements by decreasing the heavy draw-down.

---

[13] *Proceedings*, Utah Academy of Sciences, Vol. 8, p. 35 (1931).

M. R. Lewis,[14] M. Am. Soc. C. E. (by letter).—The writer is fully aware that, as Mr. Hall points out, the formulas developed in his paper are not easily applied in advance of well-drilling operations. The chief value of such theoretical studies is in securing a better understanding of the laws governing the flow of underground water. Actual drilling operations must be governed by experience and judgment. However, judgment may be improved by a better knowledge of the underlying laws.

It is quite true that underground conditions are extremely variable, and that such studies might be extended to cover many other typical cases.

Mr. Hall states that the general opinion seems to be that, under similar conditions, Type *C* wells have a smaller draw-down than either Type *A* or Type *B* wells. It occurs to the writer that this opinion is perhaps based on observations of wells with faulty screens. The formulas developed by the writer did not attempt to take into account the loss of head through screens. In the case of fine sands which are sometimes screened out by the use of fine screens, the loss of head at the screen may be very large in Type *A* or Type *B* wells. On the other hand, in Type *C* wells a large quantity of the fine sand may be pumped out of the well, thus making its effective radius comparatively large.

It is true, of course, that wells pumping from deep-seated aquifers would not be effective for drainage if these strata were separated from the uppermost water-bearing material by a truly impervious stratum. However, experience has shown that in many instances such wells are effective, even where they appear to penetrate almost impervious strata. The explanation probably is that the rate of movement downward through the comparatively impervious strata, while slow, is yet appreciable. When the very large area over which vertical downward movement may be taking place, and the gradient causing the flow, are considered, the effectiveness of such wells is readily explained.

In the paper the writer stated a conclusion that successful drainage by means of wells requires a general lowering of the water-table, unless the area to be drained is only a few hundred feet in diameter. When a general lowering of the water-table is required, the location and design of wells would be based entirely on the economics of the problem, and wells should be located and drilled to such depth as will supply water most economically. The same problem of economics applies to the depth to which the water in the well should be drawn. There are many interesting problems in this connection. Mr. Hall suggests the use of a battery of shallow wells. In some instances such batteries of wells with very low draw-down in each well may be economical. As Mr. Hall points out, the question of cost of pumping equipment is then an important factor.

Professor Israelsen is correct in his statement that the term, "transmission constant," was used by Slichter rather than the term, "transmission coefficient." He is also correct in pointing out that the definition of the transmission constant is incomplete. Perhaps it was best stated by Slichter himself,[15] as follows:

---

[14] Irrig. and Drainage Specialist, Oregon State Coll., and Div. of Agri. Eng., U. S. Dept. of Agriculture, Corvallis, Ore.

> "The constant, k, is the quantity of water that would be transmitted in unit time through a cylinder of the soil of unit length and unit cross-section under unit difference in head at the ends."

The transmission constant, k_2, suggested by Professor Israelsen, having the physical dimension of time, is numerically the same regardless of the units of force and length used in its determination. This is, unquestionably, an advantage as compared with the transmission constant, k, used by Slichter, the numerical value of which depends on the unit of length used. However, in both field and laboratory studies, units of force and length must be used. If k_2 is to be used, the appropriate value of g, the acceleration due to gravity, must be applied in determining the gradient. This fact seems to counterbalance the advantage of a constant having a single value regardless of the units of length used. Moreover, Slichter's k, or similar constants in other units, is almost universally used in the study of the flow of water through saturated materials. For these reasons the writer does not deem it wise to use the constant here represented by k_2.

As used in Equation (7), and except for the single condition that k_1 is the maximum limit of the value of w, the rate of percolation, w, and the transmission constant of the relatively impervious material, k_1, are independent constants.

As Professor Israelsen points out, the value of w is an important factor in influencing the effectiveness of drainage and the area which may be drained by a given well. It is quite probable that in the case of the Utah well mentioned, the value of w is extremely small. If this is true, the value of R would be high and, therefore, the radius of the area having a comparatively large draw-down would be large. Under such conditions a comparatively small number of wells would serve to lower the general water-table level over a large area.

DESIGN OF A REINFORCED CONCRETE SKEW ARCH[1]

By Bernard L. Weiner,[2] Jun. Am. Soc. C. E.[2a]

With Discussion by Messrs. G. D. Houtman, J. Charles Rathbun, A. A. Eremin, and Bernard L. Weiner.

Synopsis

This paper consists of:

Part I.—Analysis of the Stresses in a Skew Arch: A Restatement, Approximation, and Extension of the Original Theory by J. Charles Rathbun, M. Am. Soc. C. E.; with a Numerical Example.

Part II.—Theory of Proportioning Sections; with a Numerical Example.

Part III.—Short-Cut for Computing Crown Stresses in a Symmetrical Skew "Rigid Frame" with Hinged Ends; with a Numerical Example.

The text contains a practical description of a method of designing skew arches. Parts of it are built upon the theory first presented by Professor Rathbun, with special adaptations developed from experience in the drafting-room.

Complete derivations of formulas are given for symmetrical and unsymmetrical, and for fixed and two-hinged arches. A theory for proportioning the sections is developed which is believed to be entirely new. An approximate "short-cut" for designing Rigid Frames also forms a part of the paper. Numerical examples are given to demonstrate the theory.

The writer has assumed that his readers have a working knowledge of the design of a right arch by standard methods.

Introduction

Modern traffic conditions make the construction of a skew bridge the rule rather than the exception. The past practice of locating sharp bends in a highway on each side of a bridge in order to eliminate the skew, is no longer feasible because of the high speed of the present automobile traffic. The necessity of a scientific method of designing skew arches of the solid barrel type is thus apparent.

Analysis of the Stresses in a Skew Arch.—Until recently, very little was known about the action of a skew arch. In 1924, J. Charles Rathbun, M. Am. Soc. C. E., published his theory for the analysis of skew frames.[3] This paper gave a method for computing the total moments, thrusts, and shears acting on any section of the skew frame parallel to the abutments. The theory, as presented, applied only to symmetrical skew frames fixed at the abutments. At the request of Arthur G. Hayden, M. Am. Soc. C. E., Designing Engineer of the Westchester County Park Commission, Professor Rathbun rewrote and extended his theory to include symmetrical structures hinged at the abutments. The latter also furnished a computation for the crown stresses of a hinged, rigid-frame structure for the crossing of the Hutchinson River Parkway under Old Mamaroneck Road, Westchester County, New York (span, 56 ft.; skew angle, 33°). These manuscripts were checked by or under the direction of Henry G. Babcock, M. Am. Soc. C. E., of the Design Division of the Commission. This work has never been published.

By actual experience in the drafting-room, it was found advisable to revise the form of the equations for the analysis of the skew arch, and to make certain approximations suggested by Professor Rathbun. Part I of this paper concerns itself with this problem and also completes the theory by extending it to include unsymmetrical skew frames, both fixed and hinged at the abutments. A numerical example for a two-hinged, symmetrical rigid frame is also given.

Theory of Proportioning Sections.—The theory developed by Professor Rathbun gave merely the total moments, thrusts, and shears acting on a section of the skew frame parallel to the abutments. It did not treat the problem of distribution except in a general way. Various suggestions were made as to the distribution of the stresses produced by these forces and couples, and as to the method of proportioning the sections to resist these stresses. Upon examination, these suggestions were found to be unsatisfactory and, in most cases, scientifically unsound. Several theories for proportioning the sections were compared numerically and found to give widely varying results as to the amounts and locations of the steel areas. Part II proposes a theory for stress distribution and proportioning of the sections, which has been developed by the writer, and, although not entirely exact because of certain assumptions (especially with respect to the torsion moment), it is believed to be logical.

This part of the paper first develops the theory of the distribution of the stresses produced by the various forces and couples acting on a section of the skew frame. It then discusses the method of determining the location of the maximum stresses. In the case of a right arch the steel is perpendicular to the section to be designed, which may be called the design plane. In the case of the skew arch, the steel may not be perpendicular to the section. The effect of the angle that the steel makes with the design plane upon the stresses and deformations is determined. The usual flexural formulas for designing a right reinforced concrete section, therefore, do not apply, and new formulas are developed. The application of these formulas is explained by numerical examples.

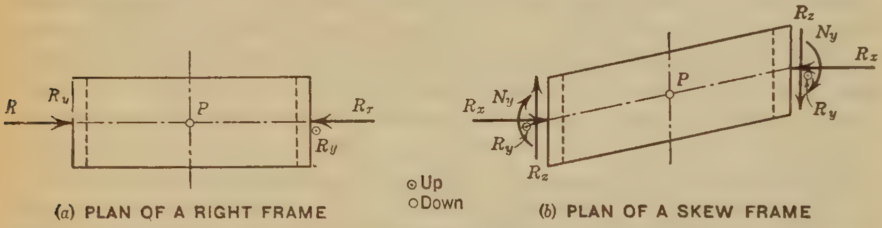
[3] *Transactions*, Am. Soc. C. E., Vol. LXXXVII (1924), p. 611.

Crown Stresses in a Symmetrical Skew Rigid Frame with Hinged Ends.—The Westchester County Park Commission builds very extensively a type of structure known as the "Rigid Frame", developed by Mr. Hayden. After designing several symmetrical skew rigid frames with hinged ends, the writer found that certain approximations could be made because of the special shape of the frame. These approximations reduce the numerical work of computing the total moments, thrusts, and shears to not much more than that required for a right arch. This "short-cut" does not extend, however, to the proportioning of the sections. Since the "rigid frame" is now being used by others besides the Westchester County Park Commission, this "short-cut" is presented here with an illustrative numerical example. It is possible that a similar approximation can be made for the fixed symmetrical, and for the fixed and the hinged unsymmetrical, "rigid frame", but no data are available to determine the closeness of such approximations.

PART I.—ANALYSIS OF THE STRESSES IN A SKEW FRAME

The skew frame is a statically indeterminate structure containing forces and moments which in general cannot be made parallel to a single plane. They must be analyzed, therefore, in three dimensions instead of in two as is done in the case of the right frame. The skew of the structure introduces forces and moments which either do not exist at all in a right frame or are present only in a small degree. For example, compare the two structures shown in plan in Fig. (1).



(a) PLAN OF A RIGHT FRAME (b) PLAN OF A SKEW FRAME

FIG. 1.—COMPARISON OF FORCES ACTING IN A RIGID FRAME WITH THOSE IN A SKEW FRAME.

In Fig. 1(*a*) the vertical load, *P*, produces the horizontal reactions, R_x, which have the same line of action and, therefore, balance each other. In Fig. 1(*b*), the two reactions, R_x, do not tend to produce translation, but they form a couple which must be resisted by other reactions. This is done by the couple formed by the two horizontal shears, R_z, and by the twisting couples in both footings, N_y. Similarly, the vertical reactions, R_y, in Fig. 1(*b*), form a couple with the load, *P*, which is resisted by a couple at each footing in the vertical planes parallel to the abutments (not shown in the diagram). These couples in the footings produce unequal soil pressure between one end of the footing and the other, exactly similar to the case of a retaining wall. In the skew frame, therefore, there are three additional reaction components which do not exist in a right arch for a load placed symmetrically with respect to the spandrel walls. The numerical values of the reactions are statically indeterminate and depend upon the geometric and elastic properties of the frame. These reactions produce three additional stresses throughout the arch which do not exist in a right arch for the condition of loading described.

In analyzing a right arch it is customary to take a section of unit width. In the case of a skew arch, the structure must be considered as a whole. In doing this, it is assumed that the load is distributed over the width of the arch ring; otherwise some error is involved. In the study prepared for the Westchester County Park Commission, Professor Rathbun states that recent experiments, some conducted by himself and some by George E. Beggs, M. Am. Soc. C. E., show that in an arch the error in this assumption is negligible. As the frames investigated here are arched and not flat slabs, this assumption of distribution is allowable.

The theory presented herein differs in several minor respects from the original theory. In the analysis of a right arch, the shear and thrust deformations are usually neglected, because they are small compared with the bending deformation. Similarly, in the skew arch, two shear deformations, one thrust deformation, and the bending deformation about the radial axis at a point midway between the spandrel walls are neglected. The theory is therefore approximate, but it is sufficiently accurate for design purposes.

The system of signs used is different from that used in the original. This change is made after a thorough study of the question with the view of facilitating the use of the theory in the drafting-room. For a similar reason, some of the details of the derivations are also changed.

METHOD OF DERIVING FORMULAS

Consider the arch as fixed at the left abutment and free to move at the right abutment, that is, a curved cantilever beam fixed at the left end. When a load is applied to the arch it will deform, causing the right abutment to deflect relative to the left abutment. Now, let a force be applied at the free end so that it returns to its original position (or to any position imposed by the condition of the ends). This force must then be equal to the reaction which would be induced at the right abutment if it were prevented from deflecting under the load. The problem then becomes one of determining the amount, direction, and point of application of a force which, applied to the free end of the cantilever, will produce a deflection equal and opposite in direction to that produced by the loading.

In general, the reaction at the right abutment (which will hereafter be designated as the reaction) will be an eccentric force inclined to the plane of the abutment. This force is replaced by a force and a couple acting at the center of the abutment, and then each is resolved into its components in the directions of the three major co-ordinate axes. Thus, there are six unknown quantities for the evaluation of which six simultaneous equations are required.

The angular deflections and linear deflections of the right abutment relative to the left abutment can each be resolved into its components in the directions of the three co-ordinate axes. These six deflection components can each be written in terms of the unknown reaction components, the external loads, and certain physical characteristics of the frame. Since the deflection due to the loading must be equal to that due to the reaction, six equations are obtained. These apply only to the fixed arch.

For the two-hinged arch, the fact that the right abutment is hinged prevents the assumption that the angular deflections about the Z-axis are equal; and the fact that the left abutment is hinged prevents the assumption that the two deflections parallel to the Y-axis are equal. Thus, there are only four equations from statically indeterminate considerations, but two more equations can be obtained from statics. With these two additional equations, the unknown components of the reaction can be evaluated.

(b) PLAN OF PORTION OF THE ARCH; LEFT-HAND SKEW

FIG. 2.—DIAGRAM ILLUSTRATING EFFECT OF THE DIRECTION OF SKEW.

NOMENCLATURE

As previously stated, a comprehensive study of the question of signs has been made with a view of facilitating the practical application of the theory. In this derivation there are factors the signs of which are more or less awkward; hence, wherever possible, this awkwardness is thrown into those terms which appear only in the derivation, but do not occur in the final equations.

The directions of the forces and co-ordinates are all referenced to the geometric properties of the structures, rather than to directions in space. For instance, T_z, which is the horizontal shear at the crown parallel to the Z-axis, is defined as positive toward the obtuse angle of the section on which it is acting. Changing the direction of skew, changes the direction of T_z in space, but it would keep the same sign because its direction with reference to the obtuse angle of the section would remain the same. In both Fig. 2(a) and Fig. 2(b) it should be noted that M_y produces compression at the obtuse corner of a left section and at the acute corner of a right section.

The nomenclature to be used in the derivation of the formulas is as follows:

P = any point on the neutral surface of the ring lying in that vertical plane which is half way between the spandrel walls.

x, y, z = the co-ordinates of P referred to axes through the crown for symmetrical arches, as shown in Fig. 5. The co-ordinates, x and y, are always positive, and z is positive in the direction toward the obtuse angle of the crown sections, so that when the right half of the arch is revolved about the line of symmetry to the position of the left section, the co-ordinates will be the same. For unsymmetrical arches, the origin of co-ordinates is taken at the center of the right abutment, as shown in Fig. 9.

u, v = the co-ordinates of the crown center referred to the tangent and radial planes through P and parallel to the plane, $z = 0$, u being parallel to the radial plane, and v, to the tangent plane. Their signs are fixed by the equations, $u = x \sin \phi - y \cos \phi$ and $v = x \cos \phi + y \sin \phi$, respectively.

u', v' = the u and v co-ordinates, respectively, of the center of the right abutment, and their signs are fixed by Equations (3) and (21) as given subsequently.

s = the length of an elementary parallelopiped measured on the square along the neutral surface.

h = rise of the neutral surface.

L = half span of the neutral surface measured on the square.

b = width of the ring measured parallel to the Z-axis (on the skew).

θ = skew angle.

ϵ = the tangent of the skew angle and is always positive.

ϕ = the angle of the slope of a plane tangent to the neutral surface at P and for the symmetrical arch is always positive (see Fig. 4). For the unsymmetrical arch, it is positive to the left and negative to the right (see Fig. 9).

I = moment of inertia of the area of the ring cut by a radial plane through P and parallel to the axis of the barrel (Z-axis), about a horizontal line through P and lying in the radial plane.

E = modulus of elasticity in tension and compression.

F = the factor of torsion.

λ = the ratio, $\dfrac{\text{Modulus of elasticity in compression}}{\text{Modulus of elasticity in shear}}$.

H = the horizontal load.

W = the vertical load.

x', y' = the x and y-co-ordinates of a load point (and apply only to the left half of the arch for the symmetrical arch).

T_x, T_y, T_z = the components of the crown thrust parallel, respectively, to the X-axis, Y-axis, and Z-axis. The component, T_x, is positive when it produces compression; T_y is positive away from the center of curvature (upward) on the left section, and toward the center of curvature (downward) on the right section of the crown; and T_z is positive toward the obtuse angle of the section on which it is acting.

M_x, M_y, M_z = the components of the crown moment about the X-axis, Y-axis, and Z-axis, respectively. The moment component, M_x, is positive when it tends to make the obtuse angle of the section on which it is acting move toward the center of curvature; M_y is positive when it produces compression at the obtuse angle of the left section, and tension at the obtuse angle of the right section, of the crown; and M_z is positive when it produces compression in the extrados fibers.

t_u, t_v, t_z = the components of the thrust acting on the surface cut by the radial plane through P, parallel to the u-axis, v-axis, and z-axis; t_u is positive away from the center of curvature on a left section, and toward the center of curvature on a right section; t_v is positive when it produces compression; and t_z is positive toward the obtuse angle of the section on which it is acting.

m_u, m_v, m_z = the components of the moment acting on the surface cut by a radial plane through P, about the u, v, and z-axes, respectively. The moment component, m_u, is positive when it causes compression at the obtuse angle of a left section and tension on the obtuse angle of a right section; m_v is positive when it causes the obtuse angle of the section on which it is acting to deflect toward the center of curvature, and m_z is positive when it produces compression in the extrados fibers.

R_x, R_y, R_z = the thrust components of the right reaction parallel to the X-axis, Y-axis, and Z-axis, respectively. Their signs are fixed by the relation that for $\phi = 90°$, $t_u = R_x$, $t_v = R_y$, and $t_z = R_z$; thus making R_x positive to the right; R_y, positive upward; and R_z, positive toward the obtuse angle of the right end of the structure as seen in plan.

N_x, N_y, N_z = the moment components of the right reaction about the X-axis, Y-axis, and Z-axis, respectively. Their signs are fixed by the relation that, for $\phi = 90°$, $m_u = N_x$, $m_v = N_y$, and $m_z = N_z$; thus making N_x positive when it tends to make the obtuse angle move up; N_y positive when it tends to make the obtuse angle move inward; and N_z positive when it produces compression in the extrados fibers.

$d\alpha, d\gamma$ = the differential angular deformation of the right face of an elementary parallelopiped relative to the left face about the v and z-axes. The positive directions of these quantities are the same as the positive directions of the moments which produce them acting on the left section; that is, m_v and m_z, respectively.

$\theta_x, \theta_y, \theta_z$ = the angular deflections of the center of the right abutment relative to the left abutment, about the x, y, and z-axes, respectively, and they are positive in the same directions as M_x, M_y, and M_z, acting on the left section of the crown. These symbols may have superscripts (R, H, or W), indicating whether the deflections are produced by the reactions, the horizontal loading, or the vertical loading.

$\Delta_x, \Delta_y, \Delta_z$ = the linear deflections of the center of the right abutment relative to the left abutment parallel to the x, y, and z-axes. The deflection, Δ_x, is positive to the right, Δ_y is positive upward, and Δ_z is positive in the same direction as the Z-axis for the right half of the arch. These symbols may also have superscripts (R, H, and W).

The factor of torsion, F, may be computed from the equation: $\frac{1}{F} = \frac{205\,\pi\,(t^2+b^2)}{180\,b^3\,t^3}$, which may be written, $\frac{1}{F} = \frac{205\,\pi}{180}\left(\frac{1}{b^3\,t} + \frac{1}{t^3\,b}\right)$, and since b is usually large compared to t, the term, $\frac{1}{b^3\,t}$, may be neglected; hence,

$$\frac{1}{F} = \frac{205\,\pi}{180\,b\,t^3} = \frac{3.578}{b\,t^3} \quad \ldots\ldots\ldots\ldots\ldots\ldots (1)$$

As the angular rotation of a shaft may be computed by the equation, $\alpha = \frac{T\,l}{E_s\,I_p}$, in which, α is the angular rotation; T, the torsion moment; l, the length of the shaft; E_s, the modulus of elasticity in shear; and I_p, the polar moment of inertia; so with a rectangular shaft the angular rotation may be computed from the formula, $\alpha = \frac{T\,l}{E_s\,F}$, in which, F has the value given in Equation (1). As the value of F enters quite prominently into the equations, reference is made to *Bulletin No. 3*, Faculty of Applied Science and Engineering, School of Engineering Research, University of Toronto, Toronto, Ont., Canada.

MATHEMATICAL DERIVATION OF FORMULAS

Consider the arch as fixed at the left abutment and free to move at the right abutment. Let the arch ring be cut by a series of radial planes. These planes may be considered as cutting the ring into blocks of lengths, S, and the portions enclosed between adjacent planes as acted upon and deformed by the forces on the section between the block and the right abutment. Each block is subjected to the thrust and moment at the right abutment and the known loads, and deformed by them. The resulting deformations of each block causes the right abutment to deflect relative to the left abutment and the total is the sum of the deflections due to each block deformation.

The derivation of the formulas falls into four steps. It is necessary to find:

1.—The stresses produced at the center of the block by the loads, and the reactions at the right abutment.

2.—The deformation of the block due to these stresses.

3.—The deflections of the right abutment relative to the left abutment due to these deformations.

4(*a*).—For the fixed arch, these deflections produced by the reactions are equated to the deflections produced by the loads.

4(*b*).—For the two-hinged arch, two additional equations are obtained from statics as already explained.

In the first case considered herein, the structure is symmetrical about a vertical line through the crown. For the sake of simplicity, the origin of the principal co-ordinates is taken where this line intersects the neutral surface and will be designated as the point, C. The Y-axis is vertical, the Z-axis is parallel to the axis of the barrel, and the X-axis is normal to the other two. (See Fig. 3.)

Owing to the symmetry of the structure, the final equations simplify if written in terms of the crown stresses rather than in terms of the reactions. For this and other reasons, as will be seen later, it is more convenient to find the forces acting on a block at its center, *P*, first in terms of the crown stresses and then to transform the resulting equations in terms of the reactions.

FIG. 3.—DIAGRAMS SHOWING POSITION OF CO-ORDINATE PLANES IN SYMMETRICAL ARCHES.

Cutting the arch in two parts by a radial plane through *C*, the half arch must be kept in equilibrium by the stresses at the crown (see Fig. 4). To find the stress at *P*, the section between the crown and *P* is taken as a free body (see Fig. 5). As it must be in equilibrium, the sum of the forces parallel to each axis and the sum of the moments about each axis must equal zero as shown in Equations (2).

Since the arch is symmetrical, for every block on the left half, there is a corresponding block on the right half. The blocks, therefore, are taken in pairs, thus reducing the algebraic work and permitting summations over one-half the arch instead of the entire arch.

SYMMETRICAL ARCHES

Equations to determine the stresses at a section of a symmetrical arch may be written as follows. (See Fig. 5.) Note that for symmetrical arches the upper signs apply to the left half of the structure, and the lower signs to the right half. The loads, W and H, apply to the left half of the structure only.

$$t_v = T_x \cos \phi \mp T_y \sin \phi + W \sin \phi - H \cos \phi \ldots\ldots (2a)$$

$$t_u = \pm T_x \sin \phi + T_y \cos \phi - W \cos \phi - H \sin \phi \ldots\ldots (2b)$$

FIG. 5.—DIAGRAM SHOWING RELATION BETWEEN CROWN STRESSES AND STRESSES AT ANY OTHER POINT.

$$m_v = T_x \varepsilon x \sin \phi \pm T_y \varepsilon x \cos \phi - T_z u + M_x \cos \phi \mp M_y \sin \phi$$
$$- W \varepsilon (x - x') \cos \phi - H \varepsilon (x - x') \sin \phi \ldots\ldots (2d)$$

$$m_u = \mp T_x \varepsilon x \cos \phi + T_y \varepsilon x \sin \phi \pm T_z v \pm M_x \sin \phi + M_y \cos \phi$$
$$- W \varepsilon (x - x') \sin \phi + H \varepsilon (x - x') \cos \phi \ldots\ldots (2e)$$

and,

$$m_z = T_x y \pm T_y x + M_z - W (x - x') - H (y - y') \ldots\ldots (2f)$$

Equations for the co-ordinates of the crown center, with respect to the point, P, of any section, may be written as follows:

$$u = x \sin \phi - y \cos \phi \tag{3a}$$

$$v = x \cos \phi + y \sin \phi \tag{3b}$$

and,

$$u' = x \sin \phi - y \cos \phi \pm L \sin \phi + h \cos \phi = u \pm L \sin \phi + h \cos \phi \tag{3c}$$

These formulas, Equations (3), are restatements of the definitions given in the nomenclature. The reactions at the right abutment may be found in terms of the crown stresses by making ϕ in Equations (2) equal to 90°; thus,

$$R_x = t_u = - T_x \tag{4a}$$

$$R_y = t_v = T_y \tag{4b}$$

$$R_z = t_z = T_z \tag{4c}$$

$$N_x = m_u = T_y \, \varepsilon \, L - T_z \, h - M_x \tag{4d}$$

$$N_y = m_v = T_x \, \varepsilon \, L - T_z \, L + M_y \tag{4e}$$

and,

$$N_z = m_z = T_x \, h - T_y \, L + M_z \tag{4f}$$

The derivation of crown stresses, in terms of reactions at the right abutment, follows from Equations (4):

$$T_x = - R_x \tag{5a}$$

$$T_y = R_y \tag{5b}$$

$$T_z = R_z \tag{5c}$$

$$M_x = R_y \, \varepsilon \, L - R_z \, h - N_x \tag{5d}$$

$$M_y = R_x \, \varepsilon \, L + R_z \, L + N_y \tag{5e}$$

and,

$$M_z = R_x \, h + R_y \, L + N_z \tag{5f}$$

Stresses at a Section Produced by the Reactions at the Right Abutment.— Substituting Equations (5) in Equations 2(d) and 2(f):

$$m_z = R_x \, (h - y) + R_y \, (L \pm x) + N_z - W \, (x - x') - H \, (y - y') \tag{6a}$$

$$\begin{aligned} m_v = {} & \mp R_x \, \varepsilon \, (L \pm x) \sin \phi + R_y \, \varepsilon \, (L \pm x) \cos \phi - R_z \, u' - N_x \cos \phi \\ & \mp N_y \sin \phi - W \, \varepsilon \, (x - x') \cos \phi - H \, \varepsilon \, (x - x') \sin \phi \end{aligned} \tag{6b}$$

The equations for the deformations of an elementary parallelopiped due to stresses at its center, P, are:

$$E \, d\gamma = m_z \frac{s}{I} \tag{7a}$$

$$E \, d\alpha = m_v \frac{\lambda \, s}{F} \tag{7b}$$

There are four more deformations; that is, two shear, one thrust, and the bending deformation about the U-axis. As already explained these four deformations are small compared to $d\alpha$ and $d\gamma$, and will be neglected.

In Equations (8A), Equations (6) have been rewritten by taking each reaction or load in turn and making the remaining terms zero. The equations listed, therefore, are for the stresses at a section, due to each reaction component at the right abutment.

Equations (*8A*).—Stresses at a section due to each reaction component at the right abutment, are:

Reaction component.	LEFT SIDE OF ARCH.		RIGHT SIDE OF ARCH.	
	m_z.	m_v.	m_z.	m_v.
R_x	$R_x (h - y)$	$-R_x \epsilon (L + x) \sin \phi$	$R_x (h - y)$	$R_x \epsilon (L - x) \sin \phi$
R_y	$R_y (L + x)$	$+R_y \epsilon (L + x) \cos \phi$	$R_y (L - x)$	$R_y \epsilon (L - x) \cos \phi$
R_z	....	$-R_z u'$	....	$-R_z u'$
N_x	....	$-N_x \cos \phi$	....	$-N_x \cos \phi$
N_y	....	$-N_y \sin \phi$	....	$+N_y \sin \phi$
N_z	N_z	....	N_z	....

Equations (*8B*).—Stresses at a section due to a vertical load, W, at a point, $x = x'$; $z = \varepsilon x'$, are similarly given by:

and,
$$\left.\begin{aligned} m_z &= - W (x - x') \\ m_v &= - W \varepsilon (x - x') \cos \phi \end{aligned}\right\} \dots\dots\dots\dots (8B)$$

Equations (*8C*).—Stresses at a section, due to a horizontal load, H, at a point, $y = y'$; $z = \varepsilon x'$, are:

and,
$$\left.\begin{aligned} m_z &= - H (y - y') \\ m_v &= - H \varepsilon (x - x') \sin \phi \end{aligned}\right\} \dots\dots\dots\dots (8C)$$

Equations (8*A*) give the moments produced by the individual reactions and, when combined, are used together with either Equations (8*B*), or Equations (8*C*), as will be shown later.

Equations (9) give the differential deflections of the right abutment relative to the left abutment, due to the deformation of a pair of corresponding elementary parallelopipeds.

Equations (*9*).—Differential deflections of the right abutment are:

Deflection.	LEFT SIDE.		RIGHT SIDE.		Equation No.
	Due to m_z.	Due to m_v.	Due to m_z.	Due to m_v.	
$d\theta_x$	....	$d\alpha \cos \phi$	....	$d\alpha \cos \phi$	(9*a*)
$d\theta_y$	....	$-d\alpha \sin \phi$	....	$d\alpha \sin \phi$	(9*b*)
$d\theta_z$	$d\gamma$	....	$d\gamma$	....	(9*c*)
$d\Delta_x$	$d\gamma (h - y)$	$-d\alpha \epsilon (L + x) \sin \phi$	$d\gamma (h - y)$	$d\alpha \epsilon (L - x) \sin \phi$	(9*d*)
$d\Delta_y$	$d\gamma (L + x)$	$d\alpha \epsilon (L + x) \cos \phi$	$d\gamma (L - x)$	$d\alpha \epsilon (L - x) \cos \phi$	(9*e*)
$d\Delta_z$	....	$d\alpha u'$	....	$d\alpha u'$	(9*f*)

Differential Deflections of the Right Abutment Produced by the Reactions.—Substituting Equations (7) and (8*A*) in Equations (9), Equation (9*a*), for example, is expanded into the form:

$$E\, d\theta_x^R = R_x \left[- \varepsilon (L + x) \sin \phi \cos \phi \, \lambda \frac{s}{F} + \varepsilon (L - x) \sin \phi \cos \phi \, \lambda \frac{s}{F} \right]$$
$$+ R_y \left[\varepsilon (L + x) \cos^2 \phi \, \lambda \frac{s}{F} + \varepsilon (L - x) \cos^2 \phi \, \lambda \frac{s}{F} \right]$$

$$+ R_z \left[- u'_L \cos\phi\,\lambda \frac{s}{F} - u'_R \cos\phi\,\lambda \frac{s}{F} \right] + N_x \left[- 2\cos^2\phi\,\lambda \frac{s}{F} \right]$$
$$+ N_y \left[- \sin\phi\cos\phi\,\lambda \frac{s}{F} + \sin\phi\cos\phi\,\lambda \frac{s}{F} \right] \ldots\ldots\ldots (10a)$$

The equations for the deflections corresponding to Equations (9*b*), (9*c*), etc., are similarly obtained and are not shown.

Total Deflections of the Right Abutment Produced by the Reactions (in Terms of the Crown Stresses).—Equations (11) give the total deflections of the right abutment relative to the left produced by the reactions, and are in terms of the crown stresses. They are obtained by substituting Equations (4) in Equations (10).

Making the substitutions indicated and integrating or summing up over one-half the arch:

$$E\,\theta_x^R = 2 \left\{ \left[\varepsilon \sum x \sin\phi\cos\phi\,\lambda \frac{s}{F} \right] T_x - \left[\sum u \cos\phi\,\lambda \frac{s}{F} \right] T_z \right.$$
$$\left. + \left[\sum \cos^2\phi\,\lambda \frac{s}{F} \right] M_x \right\} \ldots\ldots\ldots\ldots\ldots\ldots (11a)$$

$$E\,\theta_y^R = 2 \left\{ - \left[\varepsilon \sum x \sin\phi\cos\phi\,\lambda \frac{s}{F} \right] T_y + \left[\sum \sin^2\phi\,\lambda \frac{s}{F} \right] M_y \right\} . (11b)$$

$$E\,\theta_z^R = 2 \left\{ \left[\sum y \frac{s}{I} \right] T_x + \left[\sum \frac{s}{I} \right] M_z \right\} \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (11c)$$

$$E\,\Delta_x^R = 2 \left\{ - \left[\sum y^2 \frac{s}{I} + \varepsilon^2 \sum x^2 \sin^2\phi\,\lambda \frac{s}{F} \right] T_x + \left[\varepsilon \sum u\,x \sin\phi\,\lambda \frac{s}{F} \right] T_z \right.$$
$$\left. - \left[\sum y \frac{s}{I} \right] M_z - \left[\varepsilon \sum x \sin\phi\cos\phi\,\lambda \frac{s}{F} \right] M_x \right\}$$
$$+ h\,E\,\theta_z^R + \varepsilon\,L\,E\,\theta_y^R \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (11d)$$

$$E\,\Delta_y^R = 2 \left\{ \left[\sum x^2 \frac{s}{I} + \varepsilon^2 \sum x^2 \cos^2\phi\,\lambda \frac{s}{F} \right] T_y \right.$$
$$\left. - \left[\varepsilon \sum x \sin\phi\cos\phi\,\lambda \frac{s}{F} \right] M_y \right\} + L\,E\,\theta_z^R + \varepsilon\,L\,E\,\theta_x^R \ldots (11e)$$

and,

$$E\,\Delta_z^R = 2 \left\{ \left[\varepsilon \sum u\,x \sin\phi\,\lambda \frac{s}{F} \right] T_x - \left[\sum u^2 \lambda \frac{s}{F} \right] T_z \right.$$
$$\left. + \left[\sum u \cos\phi\,\lambda \frac{s}{F} \right] M_x \right\} - L\,E\,\theta_y^R + h\,E\,\theta_x^R \ldots\ldots (11f)$$

Total Deflections of the Right Abutment Produced by a Vertical Load at the Point, $x = x'$, $z = \varepsilon\,x'$.—Substituting Equations (7) and (8)*B* in Equations (9), and bearing in mind that a load deforms only that part of the structure between the left abutment and the load:

$$E\,\theta_x^W = \left[- \varepsilon \sum_A^P x \cos^2\phi\,\lambda \frac{s}{F} + \varepsilon\,x' \sum_A^P \cos^2\phi\,\lambda \frac{s}{F} \right] W \ldots\ldots (12a)$$

$$E\,\theta_y^W = \left[\varepsilon \sum_A^P x \sin\phi\cos\phi\,\lambda \frac{s}{F} - \varepsilon\,x' \sum_A^P \sin\phi\cos\phi\,\lambda \frac{s}{F} \right] W . (12b)$$

$$E\,\theta_z^{\,W} = \left[-\sum_A^P x\,\frac{s}{I} + x'\sum_A^P \frac{s}{I}\right] W \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (12c)$$

$$\begin{aligned} E\,\Delta_x^{\,W} = \Bigg[&\sum_A^P x\,y\,\frac{s}{I} - x'\sum_A^P y\,\frac{s}{I} + \varepsilon^2\sum_A^P x^2 \sin\phi\cos\phi\,\lambda\,\frac{s}{F} \\ &- \varepsilon^2 x'\sum_A^P x\sin\phi\cos\phi\,\lambda\,\frac{s}{F}\Bigg] W + h\,E\,\theta_z^{\,W} + \varepsilon\,L\,E\,\theta_y^{\,W} \ldots (12d) \end{aligned}$$

$$\begin{aligned} E\,\Delta_y^{\,W} = \Bigg[&-\sum_A^P x^2\,\frac{s}{I} + x'\sum_A^P x\,\frac{s}{I} - \varepsilon^2\sum_A^P x^2\cos^2\phi\,\lambda\,\frac{s}{F} \\ &+ \varepsilon^2 x'\sum_A^P x\cos^2\phi\,\lambda\,\frac{s}{F}\Bigg] W + L\,E\,\theta_z^{\,W} + \varepsilon\,L\,E\,\theta_x^{\,W} \ldots\ldots (12e) \end{aligned}$$

and,

$$\begin{aligned} E\,\Delta_z^{\,W} = \Bigg[&-\varepsilon\sum_A^P u\,x\cos\phi\,\lambda\,\frac{s}{F} + \varepsilon\,x'\sum_A^P u\cos\phi\,\lambda\,\frac{s}{F}\Bigg] W \\ &+ h\,E\,\theta_x^{\,W} - L\,E\,\theta_y^{\,W} \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (12f) \end{aligned}$$

Total Deflections of Right Abutment Produced by Horizontal Load at the Point, $y = y'$ *and* $z = \varepsilon\,x'$.—Similarly, substituting Equations (7) and (8*C*) in Equations (9):

$$E\,\theta_x^{\,H} = \left[-\varepsilon\sum_A^P x\sin\phi\cos\phi\,\lambda\,\frac{s}{F} + \varepsilon\,x'\sum_A^P \sin\phi\cos\phi\,\lambda\,\frac{s}{F}\right] H. (13a)$$

$$E\,\theta_y^{\,H} = \left[\varepsilon\sum_A^P x\sin^2\phi\,\lambda\,\frac{s}{F} - \varepsilon\,x'\sum_A^P \sin^2\phi\,\lambda\,\frac{s}{F}\right] H \ldots\ldots\ldots\ldots (13b)$$

$$E\,\theta_z^{\,H} = \left[-\sum_A^P y\,\frac{s}{I} + y'\sum_A^P \frac{s}{I}\right] H \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (13c)$$

$$\begin{aligned} E\,\Delta_x^{\,H} = \Bigg[&\sum_A^P y^2\,\frac{s}{I} - y'\sum_A^P y\,\frac{s}{I} + \varepsilon^2\sum_A^P x^2\sin^2\phi\,\lambda\,\frac{s}{F} \\ &- \varepsilon^2 x'\sum_A^P x\sin^2\phi\,\lambda\,\frac{s}{F}\Bigg] H + h\,E\,\theta_z^{\,H} + \varepsilon\,L\,E\,\theta_y^{\,H} \ldots\ldots (13d) \end{aligned}$$

$$\begin{aligned} E\,\Delta_y^{\,H} = \Bigg[&-\sum_A^P x\,y\,\frac{s}{I} + y'\sum_A^P x\,\frac{s}{I} - \varepsilon^2\sum_A^P x^2\sin\phi\cos\phi\,\lambda\,\frac{s}{F} \\ &+ \varepsilon^2 x'\sum_A^P x\sin\phi\cos\phi\,\lambda\,\frac{s}{F}\Bigg] H + L\,E\,\theta_z^{\,H} + \varepsilon\,L\,E\,\theta_x^{\,H} \ldots\ldots (13e) \end{aligned}$$

and,

$$\begin{aligned} E\,\Delta_z^{\,H} = \Bigg[&-\varepsilon\sum_A^P u\,x\sin\phi\,\lambda\,\frac{s}{F} + \varepsilon\,x'\sum_A^P u\sin\phi\,\lambda\,\frac{s}{F}\Bigg] H \\ &- L\,E\,\theta_y^{\,H} + h\,E\,\theta_x^{\,H} \ldots\ldots\ldots\ldots\ldots\ldots (13f) \end{aligned}$$

Symmetrical Fixed Arch

If the abutments are considered fixed, all the deflections produced by a load or by temperature expansion (or contraction) are equal and opposite to the deflections produced by the reactions. (See Equations (14).)

EQUATIONS (14).—SHOWING EQUALITY OF DEFLECTIONS PRODUCED IN A FIXED ARCH BY A LOAD OR BY TEMPERATURE.

Reactions.	For vertical load.	For horizontal load.	For temperature rise.	Equation No.
$\Delta_x^R =$	$-\Delta_x^W$	$-\Delta_x^H$	$-2ctL$	(14*a*)
$\Delta_z^R =$	$-\Delta_z^W$	$-\Delta_z^H$	$-2\epsilon ctL$	(14*b*)
$\theta_x^R =$	$-\theta_x^W$	$-\theta_x^H$	0	(14*c*)
$\theta_z^R =$	$-\theta_z^W$	$-\theta_z^H$	0	(14*d*)
$\Delta_y^R =$	$-\Delta_y^W$	$-\Delta_y^H$	0	(14*e*)
$\theta_y^R =$	$-\theta_y^W$	$-\theta_y^H$	0	(14*f*)

Equations (14) may be rewritten as given in Equations (15). (See page 1227.)

Substituting in Equations (15) the values previously obtained in Equations (11), (12), and (13), the final equations (in terms of the crown stresses) for the fixed symmetrical arch are obtained. These, with other final equations, are given in Appendix I, for the convenience of the designer. They are numbered Equations (16) in order to help the designer in referring back to the text when necessary.

Symmetrical Two-Hinged Arch

As in the case of a right arch, if the abutments are considered hinged,

$$\Delta_y^R + \Delta_y^H \neq 0;\ \Delta_y^R + \Delta_y^W \neq 0;\ \text{and}\ \theta_z^R + \theta_z^H \neq 0;\ \theta_z^R + \theta_z^W \neq 0$$

and two additional Equations (17) are obtained from statics which take the place of Equations (14*d*) and (14*e*).

EQUATIONS (17).—ADDITIONAL FORMULAS FOR HINGED ABUTMENTS.

	For vertical load, W.	For horizontal load, H.	For temperature rise.	Equation No.
$M_z + h\,T_x =$	$\frac{1}{2}(L - x')\,W$	$\frac{1}{2}(h - y')\,H$	0	(17*d*)
$T_y = R_y =$	$\frac{1}{2}\left(1 - \frac{x'}{L}\right)W$	$\frac{1}{2}\left(\frac{h - y'}{L}\right)H$	0	(17*e*)

Equations (14*a*), (14*b*), (14*c*), and (14*f*) still hold true; that is, these four equations with Equations (17*d*) and (17*e*), are the required six formulas and they may be rewritten as given in Equations (18). (See page 1228.)

Substituting in Equations (18) the values previously obtained in Equations (11), (12), and (13), and eliminating M_z between Equations (18*d*) and the equation obtained by expanding Equation (18*a*), the final Equations (19) (in terms of the crown stresses), for the two-hinged symmetrical arches, are obtained. These are placed in the Appendix with the fixed arch equations.

EQUATIONS (15).—OBTAINED BY RE-ARRANGING EQUATIONS (14).

	For vertical load.	For horizontal load.	For temperature rise.	Equation No.
$-\frac{1}{2} E \left(\Delta_x{}^R - h\,\theta_z{}^R - \epsilon\,L\,\theta_y{}^R\right) =$	$+\frac{1}{2} E \left(\Delta_x{}^W - h\,\theta_z{}^W - \epsilon\,L\,\theta_y{}^W\right)$	$+\frac{1}{2} E \left(\Delta_x{}^H - h\,\theta_z{}^H - \epsilon\,L\,\theta_y{}^H\right)$	$+E\,c\,t\,L$	(15*a*)

EXAMPLE 1.—ANALYSIS OF A TWO-HINGED SKEW FRAME

The following numerical example based on the two-hinged skew rigid frame, shown in Fig. 6, illustrates the preceding theory. Where possible, only such portions of the analysis which differ from the design of a right arch are given in detail. The work is carried through in detail to the point of obtaining influence lines, dead load, and temperature stresses. Maximum moments, shears, and thrusts are obtained in the usual manner, and the results only are given. It should be noticed, however, that in a right arch, the bending moment is most important in determining the combination of loading to produce the maximum stresses; and the thrusts are obtained for the same condition and position of loading as for the bending moment. Similarly, in a skew arch, m_z governs, and all the other stresses are obtained for the same kind of loading as is used for this moment.

FIG. 6.—DESIGN SECTION (NORMAL TO ABUTMENTS).

Table 1 gives the elastic and geometric constants required for the evaluation of the coefficients of Equations (19).

The constants from Table 1 are substituted in the expressions for the coefficients given in Equations (19). (See Tables 2, 3, and 4.)

The unit load coefficients from Table 3 are multiplied by the dead load concentrations from Fig. 6, giving the dead load coefficients in Table 5. Similarly, the coefficients of Table 4 are multiplied by the earth pressure concentrations from Fig. 6, giving the earth pressure coefficients in Table 5.

From Tables 2, 3, and 5, the coefficients are substituted in Equations (19) which are then solved for the unknown reactions as shown in Table 6.

In practical design, Items 11, 15, 20, 25, 27, and 32 (Table 6) should be incorporated in a new and condensed table for the convenience of the

$+\varepsilon^2 \Sigma x^2 \sin^2\phi \frac{b\lambda}{F}$	$= 1.420 \times 1\,000$	$= 1\,420$
$\frac{b K_{11}}{s}$		$= 6\,531$
$\frac{b K_2}{s} = -\varepsilon \Sigma u x \sin\phi \frac{b\lambda}{F}$	$= -1.192 \times 1\,051$	$= -1\,253$
$\frac{b K_3}{s} = \varepsilon \Sigma x \sin\phi \cos\phi \frac{b\lambda}{F}$	$= 1.192 \times 3.60$	$= 4.291$
$\frac{b K_5}{s} = \Sigma u^2 \frac{b\lambda}{F}$	$= 1\,109$	$= 1\,109$
$\frac{b K_6}{s} = -\Sigma u \cos\phi \frac{b\lambda}{F}$	$= (-0.083)$	$= +0.083$
$\frac{b K_7}{s} = \Sigma \cos^2\phi \frac{b\lambda}{F}$	$= 8.982$	$= +8.982$
$\frac{b K_{10}}{s} = -\Sigma \sin^2\phi \frac{b\lambda}{F}$	$= -2.192$	$= -2.192$
$-\Sigma y \frac{b}{I}$	$= -42.6$	$= -42.6$
$+h \Sigma \frac{b}{I}$	$= 20.5 \times 15$	$= 307.5$
		$+ 264.9$

Where these curves should reach zero or unity at the point, $x = 20.6$, they do not do so for points along the abutment, because of a negligible approximation in the computation.

In a frame of the type shown in Fig. 6, the two critical sections are the crown and the springing line. It is customary to design these two sections first to test the adequacy of the assumed frame. If these two sections are about the right dimensions (small changes being unimportant), other sections are designed in order to determine the reinforcing steel patterns. Table 8 gives the total stresses for the two critical sections. The right half of the

TEMPERATURE (FOR 100° RISE)							

$$C_{11}\frac{b}{s} = \frac{b}{s}\,E\dagger c\,t\,L = \frac{66.9}{3.52} \times 432\,000 \times 0.0000065 \times 100 \times 20.6 = 110\,000$$

$$C_2\frac{b}{s} = \epsilon\,C_{11}\frac{b}{s} = \epsilon \times 110\,000 = 131\,500$$

$$C_8 = C_{14} = C_{15} = C_6 = 0$$

*These values are interpolated.

†For $n = 10$, $E_c = 30\,000$ kips per sq. in. ÷ 10 = 432 000 kips per sq. ft.

It should be noted that the weight of the abutments has been omitted from the computations because the influence lines for the crown stresses are all zero over the reactions. In computing the direct thrust, t_v, for sections along the abutment, the weight of the wall should be included. Having the maximum stresses, the sections can now be proportional. This portion of the numerical work will be given in Part II, Example 2, where the "Theory of Proportioning Sections" is discussed.

UNSYMMETRICAL ARCHES

It is usually advantageous to take the origin either at the movable end of the transformed structure, or at the point of symmetry. The origin is, therefore, taken at the right abutment which is considered the movable end. (See Fig. 9.)

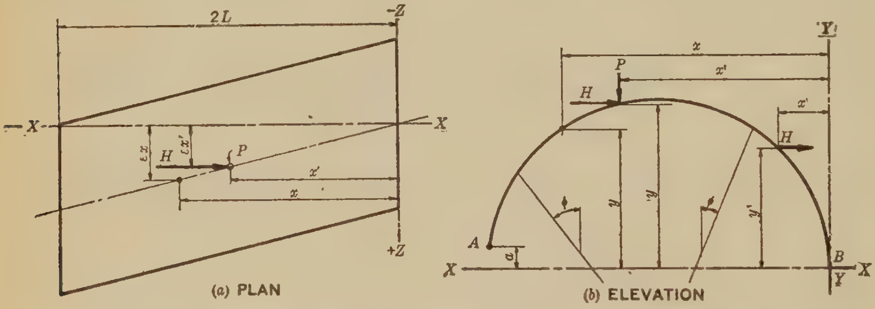

FIG. 9.—DIAGRAMS SHOWING POSITION OF CO-ORDINATE AXES FOR UNSYMMETRICAL ARCHES.

The stresses at a section of an unsymmetrical arch in terms of the reactions may be found by substituting Equations (5) in Equations (2), and transferring the origin to the center of the right abutment:

$$t_v = -R_x \cos\phi - R_y \sin\phi + W \sin\phi - H \cos\phi \quad \text{(20a)}$$

$$t_u = -R_x \sin\phi + R_y \cos\phi - W \cos\phi - H \sin\phi \quad \text{(20b)}$$

$$t_z = R_z \quad \text{(20c)}$$

$$m_u = R_x\,\varepsilon\,x\cos\phi + R_y\,\varepsilon\,x\sin\phi + R_z\,v' - N_x\sin\phi + N_y\cos\phi$$
$$- W\,\varepsilon\,(x - x')\sin\phi + H\,\varepsilon\,(x - x')\cos\phi \ldots\ldots\ldots\ldots (20d)$$

$$m_v = - R_x\,\varepsilon\,x\sin\phi + R_y\,\varepsilon\,x\cos\phi - R_z\,u' - N_x\cos\phi - N_y\sin\phi$$
$$- W\,\varepsilon\,(x - x')\cos\phi - H\,\varepsilon\,(x - x')\sin\phi \ldots\ldots\ldots\ldots (20e)$$

and,

$$m_z = R_x\,y + R_y\,x + N_z - W\,(x - x') + H\,(y - y') \ldots\ldots\ldots\ldots (20f)$$

The equations of the co-ordinates of the center of the right abutment with respect to the point, P, of any section may be written as follows:

$$u' = x\sin\phi + y\cos\phi \ldots\ldots\ldots\ldots (21a)$$

and,

$$v' = x\cos\phi - y\sin\phi \ldots\ldots\ldots\ldots (21b)$$

The deformation formulas for this case are identical with Equation (7):

$$E\,d\,\gamma = m_z\,\frac{s}{I} \ldots\ldots\ldots\ldots (22a)$$

and,

$$E\,d\,\alpha = m_v\,\frac{\lambda\,s}{F} \ldots\ldots\ldots\ldots (22b)$$

Equations (20*e*) and (20*f*) have been rewritten by taking each reaction or load in turn and making the remaining terms zero. Equations (23*A*), therefore, are for the stresses at a section due to each reaction component at the right abutment.

EQUATIONS (23*A*).—STRESSES AT A SECTION DUE TO REACTION COMPONENTS.

Reaction component.	m_z.	m_v.
R_x	$R_x\,y$	$-R_x\,\epsilon\,x\sin\phi$
R_y	$R_y\,x$	$R_y\,\epsilon\,x\cos\phi$
R_z	....	$-R_z\,u'$
N_x	....	$-N_x\cos\phi$
N_y	....	$-N_y\sin\phi$
N_z	N_z	....

Stresses at a section due to a vertical load, W, at a point, $x = x'$, $z = \varepsilon\,x'$, are similarly given by:

$$\left.\begin{aligned} m_z &= - W\,(x - x') \\ m_v &= - W\,\varepsilon\,(x - x')\cos\phi \end{aligned}\right\} \ldots\ldots\ldots\ldots (23B)$$

and,

Stresses at a section due to the horizontal load, H, at a point, $y = y'$, $z = \varepsilon\,x'$, are:

$$\left.\begin{aligned} m_z &= + H\,(y - y') \\ m_v &= - H\,\varepsilon\,(x - x')\sin\phi \end{aligned}\right\} \ldots\ldots\ldots\ldots (23C)$$

and,

As in the case of the symmetrical arches, Equations (23*A*), when combined, are used, together with Equations (24*B*) and (24*C*).

Following the method used for the symmetrical arches, Equations (22) and (23) are substituted in Equations (24). For the fixed arch, all the deflections produced by the loads are equated to the deflections produced by the reactions resulting in the final Equations (25), which are placed in the Appendix for the convenience of the designer. As in the case of Equations (16), the text numbering is used in the Appendix for convenience in referring back to the text when necessary.

EQUATIONS (24).—DIFFERENTIAL DEFLECTIONS OF THE RIGHT ABUTMENT.

Deflection.	Due to m_z.	Due to m_v.
$d\theta_x$	......	$d\gamma \cos \phi$
$d\theta_y$	......	$-d\alpha \sin \phi$
$d\theta_z$	$d\gamma$	....
$d\Delta_x$	$d\gamma\ y$	$-d\alpha\ \epsilon\ x \sin \phi$
$d\Delta_y$	$d\gamma\ x$	$d\alpha\ \epsilon\ x \cos \phi$
$d\Delta_z$	......	$d\alpha\ u'$

For the two-hinged arch, the fact that the left abutment is hinged prevents the assumption that the vertical deflections produced by the reactions and the loads are equal, and the fact that the right abutment is hinged prevents a similar assumption for the angular deflection of the right abutment about the Z-axis. Two additional equations are obtained from statics as in the case of the symmetrical arch, but in this case a correction must be made for the fact that the two abutments are not at the same elevation.

The structure has been transformed into a curved cantilever beam and the load has caused the right abutment to deflect vertically. Replacing the hinge in the left abutment, the entire arch is rotated until the right abutment returns to its original elevation. This rotation is about the Z-axis and corresponds to a γ-deflection. From Equation (24), it is seen that such an angular deflection produces a linear deflection along the X-axis, or a Δ_x. The Δ_x already derived for each load or reaction, therefore, must be corrected for this additional γ-deflection. These deflections will be denoted by the same symbols used previously, but primed.

In Fig. 10, the arch acting as a cantilever beam is deflected by the loads (not shown) so that B moves to B'. When the hinge at A is replaced, B' moves to B'', and the deflection, Δ_x, must be corrected by the amount, $B''\,D$.

Since γ' is small, $\angle\ AB''\ B'$ may be considered a right angle, so that $\angle\ B''\ B'\ D = \angle\ E$. From similar triangles: $\dfrac{a}{2\ L} = \dfrac{B''\ D}{B'\ D} = \dfrac{B''\ D}{\Delta_y}$ or,

$$B''\ D = \left(\frac{a}{2\ L}\right) \Delta_y$$

The final deflection along the X-axis is $B\ B''$; and $B\ B'' = B\ D - B''\ D$. Therefore,

$$\Delta'_x = \Delta_x - \left(\frac{a}{2\ L}\right) \Delta_y \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (26)$$

For the two-hinged unsymmetrical arch, the Δ'_x produced by the loads must equal the Δ'_x produced by the reactions. For the symmetrical arch, $a = 0$, and $\Delta'_x = \Delta_x$.

Four equations are obtained by equating the deflections, and two more are obtained from statics, resulting in the six final Equations (27). (See Appendix I.)

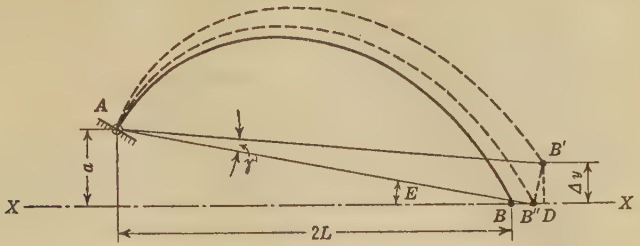

FIG. 10.

SUMMARY

This concludes Part I, which gives the derivation of the four sets of equations for obtaining the total stresses for the fixed and hinged arches, which may be either symmetrical or unsymmetrical. The unsymmetrical arch equations can be used for symmetrical arches, but would involve more numerical work. It should be remembered that the thrust, shears, and the bending deformations about the radial axes have been omitted. For large and important arches, the preceding theory should not be used without correction, or by an adjustment similar to that made for right arches.

PART II.—THEORY OF PROPORTIONING SECTIONS

The analysis of a structure may be divided into three parts:

(*a*) The computation of the forces and moments produced by the external loading at several sections of the structure.
(*b*) The distribution of the stresses over these sections.
(*c*) Design of the sections to resist the stresses acting on them.

The numerical work up to this point gives in detail all the steps necessary for plotting influence lines and the maximum moments, thrusts, and shears have been obtained from these curves in the usual way. The next step is to determine the distribution of the stresses over a section.

NOTATION

To the notation already given, the following symbols are added. In the design formulas, the standard reinforced concrete notation is used with the exceptions and additions noted. Symbols which are used only in the derivations, but which do not appear in the final formulas, are defined in the text and are not given here. Unless otherwise stated, symbols are always positive.

e = the distance from the intrados steel to the resultant normal thrust or horizontal shear acting on a section, and is positive in the direction away from the center of curvature of the arch.
e' = the same as e, except that it is measured from the extrados steel.
f_s = the unit stress in the steel in the intrados face; it is positive when the steel is in tension.
f_s' = the unit stress in the steel in the extrados face; it is positive when the steel is in tension.

f_c = the unit direct stress in the concrete; it is positive when the concrete is in compression.

h = the unit horizontal shearing stress in the concrete and is positive when it tends to rotate the concrete element on which it is acting, in the same direction in which a positive T_z (or t_z) tends to cause rotation.

j = the distance from the center of compression or the center of shear in the concrete to the intrados steel.

j' = the same as j, except that it is measured to the extrados steel.

q = a constant similar to k used in connection with the condition of compression or horizontal shear over the entire section. Its meaning is obvious from the text. It is positive when the stress at the intrados is numerically less than, or of opposite sign to, the stress at the extrados.

r = the distance between the intrados and extrados steel.

M = the direct moment per unit width acting on a design plane and is positive when it produces compression in the extrados fibers.

M_s = the horizontal shear moment per unit width acting on a design plane. Considering this moment as composed of two equal and opposite horizontal forces, it is positive when these forces tend to rotate the concrete element in the same direction in which the corresponding forces of the moment, m_v (or M_x), tend to cause rotation.

N = the direct thrust per unit width acting on a design plane and is positive when it produces compression.

S = the horizontal shear per unit width acting on a design plane and is positive in the same direction as h.

m = the direct moment per unit width acting on a plane perpendicular to the V-axis and is positive when it produces compression in the extrados fibers.

m' = the same as m, but acting on a plane perpendicular to the Z-axis.

t_n, t_n' = the direct thrust per unit width corresponding to m and m', respectively, and are positive when they produce compression.

m_s = the horizontal shear moment per unit width acting on a plane perpendicular to the V-axis and is positive in the same direction as m_v (or M_x).

m_s' = the horizontal shear moment per unit width acting on a plane perpendicular to the Z-axis and is positive in the same direction as M_s.

t_s = the horizontal shear per unit width corresponding to m_s and is positive in the same direction as t_z (or T_z).

t_s' = the horizontal shear per unit width corresponding to m_s' and is positive in the same direction as h.

V = the radial shear per unit width acting on a plane perpendicular to the V-axis and is positive in the same direction as t_u.

V' = the radial shear per unit width acting on a plane perpendicular to the Z-axis and is positive in the direction opposite to the positive direction of the shear, V, acting on the unbalanced triangle, $A\,C\,D$ (Fig. 16(*a*)).

α = the angle between the direction of the steel and the direction of a design plane, and is positive in the same direction as m_u (or M_y).

ψ = the angle between a plane perpendicular to the V-axis and a design plane and is positive in the same direction as m_u (or M_y).

θ' = the skew angle measured in the plane tangent to the neutral surface at any point. It corresponds to the angle, θ, measured in the horizontal plane.

ϕ' = the central angle measured in a plane parallel to the face of the bridge. It corresponds to the central angle, ϕ, measured in a plane perpendicular to the abutments.

RELATION BETWEEN θ' AND θ AND BETWEEN ϕ' AND ϕ

Before entering upon the second step of the analysis—the stress distribution—the relation between θ' and θ and between ϕ' and ϕ will be found.

From Fig. 11: $\tan\theta' = \cos\phi \tan\theta$, or,

$$\varepsilon' = \varepsilon \cos\phi \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (28)$$

Also, $\tan\phi' = \dfrac{\sin\phi}{\cos\phi \sec\theta}$, or

$$\tan\phi' = \tan\phi \cos\theta \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (29)$$

FIG. 11.

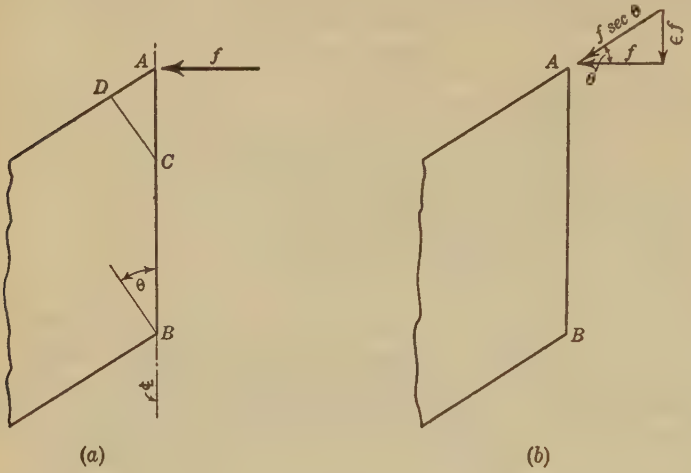
The relation between ϕ' and ϕ is convenient when laying out the arch for the purpose of scaling the properties of the sections. The intrados and extrados curves are usually determined in a plane parallel to the face of the bridge, while for the purposes of design, the arch must be laid out in a plane perpendicular to the abutments. This relation, therefore, gives a convenient method of finding ϕ which appears in the skew arch analysis. The relation between ϵ' and ϵ is important, because the former is used in the design of the steel at sections other than the crown.

SECTION 1.—STRESS DISTRIBUTION

Before the steel can be designed, the distribution of the stresses at any section produced by the various moments, shears, and thrusts must be determined. For simplicity, the crown section is analyzed in the introductory analysis, *A*, which follows. For other sections, the analysis is the same except that the sections are not vertical and the planes tangent to the neutral surface are not horizontal. The angle, θ', is then used instead of the angle, θ.

(*A*) Stresses at Face of Bridge

Resultant Thrust at Face of Bridge.—In Fig. 12(*a*), f is the unit stress produced at A by the direct thrust, T_x. Since there is no material to the left of the section to resist the stress, it is impossible for f to act by itself. There must be, therefore, a unit shear acting at the point, A, of such a magnitude that the resultant stress will be parallel to the face of bridge as shown in Fig. 12(*b*). The resultant stress is evidently equal to $f \sec \theta$, and the unit shear required to bring this stress in line with the face of bridge is εf.



(*a*) (*b*)

FIG. 12.

Another way of arriving at the same result is as follows: In Fig. 12, $C\,D$ is a plane perpendicular to the face of the bridge. The stress, f, produces a unit shear on the plane, $C\,D$, and an equal unit shear on the plane, $A\,D$, which is perpendicular to the plane, $C\,D$. However, the plane, $A\,D$, is an external face and can carry no stress. Hence, there can be no shear on Plane $C\,D$, and the resultant unit stress must be normal to it, that is, parallel to the face of bridge.

Thrust and Shears on Plane Perpendicular to Z-Axis.—In Fig. 13, a thrust, T_x, acts on the crown section, $A\,B$. At A, there is a direct unit stress, f, and a unit shear, εf, as previously shown. If the triangle, $A\ C\ D$, of dimensions, dx, dz, is cut from the arch, this triangle shown enlarged in Fig. 14, is a free body and must be in equilibrium. Face $A\,C$ is an external face in the uncut arch and carries no stress. For equilibrium there must be a unit shear, h, and unit thrust, t_n, on the face, $C\,D$.

$$\text{Since } \Sigma X = 0, -h\,dx = f\,dz;\ -h = f\,\frac{dz}{dx} = \varepsilon f;\ \text{and,}$$

$$t'_s = -t_s = -\varepsilon\, t_n \ldots\ldots\ldots\ldots\ldots\ldots\ldots (30)$$

This merely proves the familiar theorem that if there is a unit shear on one plane, there must be an equal unit shear on a plane at right angles to it.

Again, for equilibrium since $\Sigma Z = 0$, $t'_n \, d x = \varepsilon \, t_n \, d z$; $t'_n = \varepsilon \, t_n \dfrac{dz}{dx} = \varepsilon^2 \, t_n$; and,

$$t'_n = \varepsilon^2 \, t_n = \varepsilon \, t_s \text{.........................} (31)$$

Furthermore, since $\Sigma Y = 0$, $V' \, dx = \dfrac{T_y}{b} \, dz = V \, dz$, and therefore,

$$V' = \varepsilon \, V \text{...........................} (32)$$

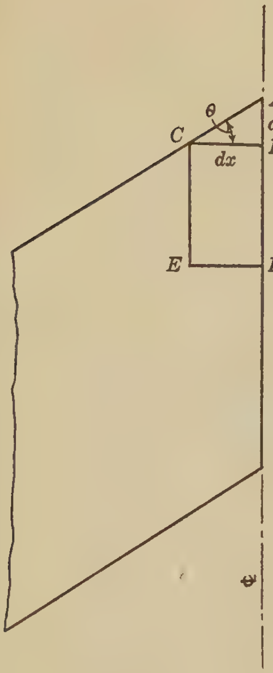


FIG. 13.—PLAN.

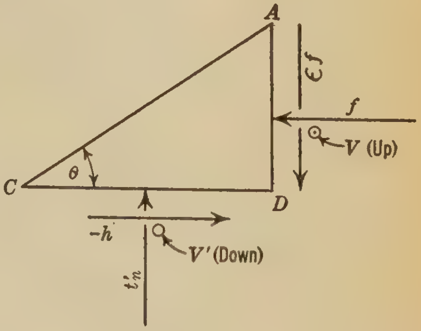

FIG. 14.

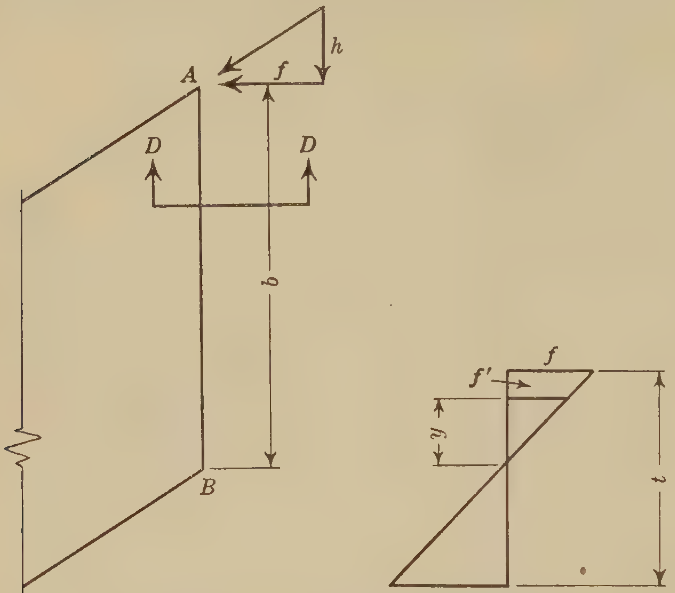
Direct Moment and Shear Moment on Plane Perpendicular to Z-Axis.— In the discussion of the direct thrust, it was shown that at the face of bridge a shear is present which makes the resultant thrust act parallel to that face. It was also shown that there is a direct thrust acting on the plane perpendicular to the section. Similar reasoning holds true for the stresses produced by M_z; but, whereas the stresses produced by the thrust, T_x, are uniformly distributed over the depth of the section, the distribution of M_z is variable.

In Fig. 15(*a*) a bending moment, M_z, acts on the crown section, $A \, B$. At A, f is the extreme fiber stress produced by the bending moment, and $h = \varepsilon \, f$ is the corresponding unit shear necessary to make the resultant stress act parallel to the face of bridge. The fiber stress at any other point on the radial line through A is f' (Fig. 15(*b*)). A corresponding unit shear, $h' = \varepsilon \, f'$, must accompany this fiber stress, f', in order that the resultant stress shall here also be parallel to the face of bridge; but f' varies along the depth, t, of the section. Therefore, h' must also vary along the depth of the section. The relation between these variables can be expressed in terms of moments; that is, $M_z = b\,\Sigma f'\,y\,dA$, or, $m = \frac{M_z}{b} = \Sigma f'\,y\,dA$; also, $\Sigma\,\varepsilon\,f'\,y\,dA = \Sigma\,h'\,y\,dA$. Therefore,

$$\varepsilon\,m = m_s \qquad (33)$$

and, similarly,

$$\varepsilon^2\,m = m' \qquad (34)$$



(a) PLAN (b) SECTION *D-D*

FIG. 15.

The moment, m_s, is part of a torsion moment. It is the summation of the moments of the horizontal shears about the horizontal center of gravity of the section. It is also the shear moment required to make the resultant bending stresses at the face of the bridge act parallel to that face.

(*B*) Stresses at Any Point of a Section

Equations (30) to (34), inclusive, give the value of certain stresses at the face of bridge. The values of these stresses at any point of the section will now be found. As in the right arch, the effect of the curvature of the arch on the stress distribution will be neglected. The error involved is small for curves of large radii.

In the following discussion, the problem of a shaft subjected to torsion is encountered again. Before a correct design of a skew arch can be made, a correct torsion formula will have to be developed. Of course, the method presented herein is not exact, but it is developed with the idea of obtaining a logical design with the data available and of pointing out some of the problems involved.

There are various formulas for analyzing a shaft subjected to torsion. Most of them are very approximate except for the circular and the square sections. The usual assumptions are that an unstressed plane section remains plane after it is stressed and that only shearing stresses are produced. These assumptions are not true except in some special cases. St. Venant developed a more accurate theory which shows that a plane surface becomes warped when the shaft is twisted. This theory, like the more approximate theories, is developed for an isotropic and homogeneous shaft of constant cross-section normal to the axis. The derivation is also based on an assumption which leads to the conclusion that the only stresses produced are shears. However, since this formula agrees with such tests as are available, it is used in the present derivation.[4]

St. Venant's theory is rather complicated; but for large ratios of $\frac{b}{t}$, $\left(\frac{b}{t} > 3\right)$, the formulas reduce to simple terms.[5] The following facts which are proved by theory and, in some cases, substantiated by tests, are used in the design:

> (*a*) The maximum shear produced by a torsion moment acting on a rectangular shaft occurs at the middle of the long side.
>
> (*b*) Along the edges, the shears vary from zero at the corners to a maximum at the middle and are parallel to the edges. For large ratios of $\frac{b}{t}$, the shears parallel to the long edges are zero at the corners, but reach a value just inside the surface, which remains practically constant. The shears are, therefore, a maximum along the entire long edge, except at the corners where they are zero. The shears parallel to the short edges have a finite value only at the surface, but quickly become zero just inside the surface. These shears are also zero at the corners and are a maximum at the middle of the short edges.
>
> (*c*) The torsion moment can be divided into two parts, one-half of which produces shears parallel to the long edge and the other half, shears parallel to the short edge.

In the following derivation, it is assumed that the thrust, (T_x, t_v), the bending moment, (M_z, m_z), and the radial shears, (T_y, t_u), are uniformly distributed over the width, b, of any radial section parallel to the center line of the span, (Z-axis).

Distribution of Horizontal Shear.—Fig. 16(*a*) is a plan view of a skew frame showing the position of a strip of differential width. The strip is enlarged in Fig. 16(*b*) for convenience in illustrating the special notation that applies. In these diagrams, let,

t_3 = unit radial shear produced by the net torsion moment;
Q = static moment of the area, $A\ F$, about the axis, $U - U$ $= \frac{1}{2}\left(\frac{b^2}{4} - z^2\right) t$;

---

[4] A short discussion of torsion is given in *Bulletin No. 3* of the University of Toronto, previously mentioned.

[5] "Applied Elasticity," by John Prescott.

$$A = b\,t;$$

$$a = A\,F \times t = \left(\frac{b}{2} - z\right) t; \text{ and,}$$

$$dv = dx \text{ (neglecting the curvature of the arch).}$$

Fig. 16.

Moments are represented as two equal and opposite forces of which only the upper force is shown in the diagrams.

Since $\Sigma\ V = 0$ for equilibrium: $t'_s\,dv = -\,m'_u\,\dfrac{Q}{I} + m_u\,\dfrac{Q}{I} - m_u\,\dfrac{z}{I}\,\varepsilon'\,t dv$ $-\,t'_v\,\dfrac{a}{A} + t_v\,\dfrac{a}{A} - \dfrac{t'_v}{b}\,\varepsilon'\,dv$, or, $t'_s = -\,\dfrac{dm_u}{dv}\,\dfrac{Q}{I} - \varepsilon'\,m_u\,\dfrac{tz}{I} - \dfrac{dt_v}{dv}\,\dfrac{a}{A} - \varepsilon'\,\dfrac{t_v}{b}$.

From Equations (2), in Part I, neglecting the effect of the curvature of the arch; that is, making $\dfrac{d\phi}{dv} = 0$; $\dfrac{dm_u}{dv} = (t_z - \varepsilon'\,t_v)$; $\dfrac{dt_v}{dv} = 0$. Furthermore, $t_s = -\,t'_s$, and therefore,

$$t_s = \frac{3}{2}\left(\frac{t_z - \varepsilon'\,t_v}{b}\right)\left(1 - 4\,\frac{z^2}{b^2}\right) + \varepsilon'\,\frac{t_v}{b} + 12\,\varepsilon'\,\frac{m_u\,z}{b^3} \ldots\ldots\ldots (35)$$

The last term of Equation (35) is usually small and can be neglected.

This equation shows that the shear, t_s, is composed of two parts: (a), that produced by the computed shear, t_z; and (b), that produced by the effect of the skew on the thrust, t_v. When $\epsilon' = 0$, the shear, t_z, has the usual parabolic distribution for a rectangular section.

Equation (35) also agrees with the statement made by Professor Rathbun[6] that the portion of the shear, T_z, which is equal to $\epsilon\ T_x$, is distributed uniformly, the remainder being distributed parabolically. In other words, a certain portion of T_z is distributed uniformly across the section so that the resultant unit stress due to T_x and this portion of T_z is at every point of the section, parallel to the face of bridge. The remaining part of T_z is distributed in the same way as in a rectangular beam. If the moment, M_y (or M_u), should be large enough to require steel reinforcement to take the tension, this remaining portion would be distributed in the same way as the shear in a rectangular reinforced concrete beam.

In a right arch, it is generally assumed that the radial shear and the bending moment have the same distribution as in a straight beam. This assumption is the same as saying that $\frac{d\phi}{dv}$ is negligible or zero. This derivative is a function of the curvature, $\left(\frac{1}{r}\right)$, and for arches of large radii, the error involved is small.

Direct Thrust on Plane Perpendicular to Z-Axis.—From Fig. 16 (b), since $\Sigma Z = 0$ for equilibrium: $t'_n = \int_z^{\frac{b}{2}} \frac{\delta t_s}{\delta v}\,dz + \varepsilon'\,t_s$, and, from Equation (35): $\frac{\delta t_s}{\delta v} = 0$. Therefore,

$$t'_n = \varepsilon'\,t_s \dots\dots\dots\dots\dots\dots\dots\dots (36)$$

Distribution of the Torsion Moment.—From Fig. 16(b), since the summation of moments about the Z-axis must be zero for equilibrium:

$$m'_s\,dv = -\,dm_z\,\frac{a}{A} - \frac{m_z}{b}\,\varepsilon'\,dv + t_u\,\frac{a}{A}\,dv + t'_u\,dv\,dz$$

$$+\left(\int_z^{\frac{b}{2}}\int_{-\frac{t}{2}}^{\frac{t}{2}} t_3\;dz\;du\right)dv + \left(\int_{-\frac{t}{2}}^{\frac{t}{2}} t_3\;du\right)dv\,dz.$$

Furthermore, since $m_s = -\,m'_s$ and $\frac{\delta m_z}{\delta v} = t_u$,

$$m_s = \frac{\varepsilon'\,m_z}{b} - \int_z^{\frac{b}{2}}\int_{-\frac{t}{2}}^{\frac{t}{2}} t_3\,dz\,du \dots\dots\dots\dots\dots\dots (37)$$

Equation (37) is similar to Equation (35) which shows that a certain portion of the horizontal shear, t_z, is distributed uniformly and the remainder is distributed the same as a shear in a similar rectangular (unskewed) beam. Similarly, Equation (37) shows that a portion of the torsion moment equal to $\varepsilon' m_z$ is distributed uniformly so that the resultant unit stresses produced by this moment and the direct moment, m_z, are at each point of the section parallel to the face of the bridge, and the remaining portion is distributed like a torsion moment. The two portions of the torsion moment are given by the first and second terms, respectively, of the right-hand member of Equation (37). The amount of the portion of this moment which is distributed like a torsion moment is still to be found. This unknown moment will be denoted by m'_v.

---

[6] *Transactions*, Am. Soc. C. E., Vol. LXXXVII (1924), p. 678.

In dealing with the torsion moment, m'_v, St. Venant's torsion formulas will be used.[7] A correct design is not possible until the problem of torsion in general is studied further and tests are made.

Integrating both sides of Equation (37) between the limits of $\frac{b}{2}$ and $-\frac{b}{2}$:

$$\int_{-\frac{b}{2}}^{\frac{b}{2}} m_s \, dz = \varepsilon' m_z - \int_{-\frac{b}{2}}^{\frac{b}{2}} \int_{z}^{\frac{b}{2}} \int_{-\frac{t}{2}}^{\frac{t}{2}} t_3 \, dz \, dz \, du \dots\dots\dots (38)$$

Substituting the value of t_3 in terms of m_v', as given by St. Venant's formulas, and performing the integrations indicated, the last term of Equation (38) can be shown to equal $-\frac{1}{2} m'_v$. Equation (38) can then be rewritten as follows:

$$\int_{\frac{b}{2}}^{\frac{b}{2}} m_s \, dz - \frac{1}{2} m'_v = \varepsilon' m_z \dots\dots\dots\dots\dots\dots (39)$$

Since the sum of the moments produced by both the horizontal shears and the radial shears acting on the entire cross-section must equal the computed moment, m_v:

$$\int_{-\frac{b}{2}}^{\frac{b}{2}} m_s \, dz - \int_{-\frac{b}{2}}^{\frac{b}{2}} \int_{-\frac{t}{2}}^{\frac{t}{2}} t_3 \, z \, dz \, du = m_v \dots\dots\dots\dots\dots (40)$$

St. Venant's formulas show that the second term of Equation (40) also equals $-\frac{1}{2} m'_v$. Therefore,

$$\int_{-\frac{b}{2}}^{\frac{b}{2}} m_s \, dz + \frac{1}{2} m'_v = m_v \dots\dots\dots\dots\dots\dots (41)$$

Eliminating the term, $\int_{-\frac{b}{2}}^{\frac{b}{2}} m_s \, dz$, between Equations (39) and (41), and solving for m'_v:

$$m'_v = m_v - \varepsilon' m_z \dots\dots\dots\dots\dots\dots\dots\dots (42)$$

---

[7] These formulas are developed by Prescott in his "Applied Elasticity," Chapter VII, pp. 148 to 156, and are used because they are the best available.

The equation for m_s can now be found. At the face of the bridge, the second term of Equation (37) is given by St. Venant's formulas as zero. At any other point, this second term reduces to a value which for large ratios of $\frac{b}{t}$ $\left(\text{that is, } \frac{b}{t} > 3\right)$, is nearly constant and equals $-\frac{m'_v}{2\,b}$. Equation (37), therefore, reduces to the following expression:

At the face of the bridge:

$$m_s = \frac{\varepsilon'\, m_z}{b} \qquad (43)$$

At any other point of the section:

$$m_s = \frac{m_v + \varepsilon'\, m_z}{2\,b} \qquad (44)$$

Two equations for the shear moment per unit width of section are necessary because, for large ratios of $\frac{b}{t}$, the torsion moment acting on a section which is normal to the sides of the shaft, produces stresses which are either zero at the surface of the short side and quickly reach a finite value just inside the surface; or, they have a finite value at the surface, and quickly reach zero just inside the surface. In a skew section, the surface stresses do not reach zero, but become a minimum which is a function of the skew angle and is produced by the effect of the skew on the bending moment, m_z.

Attention is called to the fact that the previous sentence is really the crux of the problem of the stress distribution on a skew section. The fact that the stresses on the section at the surface must be parallel to that surface is what causes the difference between the distribution on a right section and a skew section.

Bending Moment on Plane Perpendicular to Z-Axis.—From Fig. 16(*b*), since the summation of moments about the *V*-axis must be zero for equilibrium:

$$\begin{aligned} m'\,dv = {} & \int_z^{\frac{b}{2}} m''_s\,dz - \int_z^{\frac{b}{2}} m_s\,dz + m_s\,\varepsilon'\,dv - \int_z^{\frac{b}{2}}\int_{-\frac{t}{2}}^{\frac{t}{2}} t'_3\,(z' + \varepsilon'\,dv - z)\,dz\,du \\ & + \int_z^{\frac{b}{2}}\int_{-\frac{t}{2}}^{\frac{t}{2}} t_3\,(z' - z)\,dz\,du - \left(\int_{-\frac{t}{2}}^{\frac{t}{2}} t_3\,du\right)(\varepsilon'\,dv)\left(\varepsilon'\,\frac{dv}{2}\right) \\ & - t'_u\,\frac{a}{A}\left[\frac{1}{2}\left(\frac{b}{2} - z\right) + \varepsilon'\,dv\right] + t_u\,\frac{a}{A}\left[\frac{1}{2}\left(\frac{b}{2} - z\right)\right] - t'_u\,(\varepsilon'\,dv)\left(\varepsilon'\,\frac{dv}{2}\right) \end{aligned}$$

Combining and reducing,

$$\begin{aligned} m' = {} & \int_z^{\frac{b}{2}} \frac{\delta\, m_s}{\delta\, v}\,dz + \varepsilon'\,m_s - \int_z^{\frac{b}{2}}\int_{-\frac{t}{2}}^{\frac{t}{2}} \frac{\delta\, t_3}{\delta\, v}\,(z' - z)\,dz'\,du \\ & - \varepsilon'\int_z^{\frac{b}{2}}\int_{-\frac{t}{2}}^{\frac{t}{2}} t_3\,dz\,du - \frac{1}{2}\,\frac{\delta\, t_u}{\delta\, v}\,\frac{a}{A}\left(\frac{b}{2} - z\right) - \varepsilon'\,t_u\,\frac{a}{A} \qquad (45) \end{aligned}$$

From St. Venant's formulas: $t_3 = -m'_v\, f(z) = -(m_v - \varepsilon' m_z)\, f(z)$. Neglecting the curvature of the arch: $\frac{\delta t_3}{\delta v} = 0$; $\frac{\delta t_u}{\delta v} = 0$. Differentiating Equation (37): $\frac{\delta m_s}{\delta v} = \frac{\varepsilon' t_u}{b}$.

Substituting these values in Equation (45):

$$m' = \varepsilon' m_s - \varepsilon' \int_z^{\frac{b}{2}} \int_{-\frac{t}{2}}^{\frac{t}{2}} t_3\, dz\, du \ldots\ldots\ldots\ldots (46)$$

Eliminating the double integral between Equations (37) and (46),

$$m' = 2\, \varepsilon' m_s - \varepsilon'^2 \frac{m_z}{b} \ldots\ldots\ldots\ldots (47)$$

Referring to Equations (43) and (44), Equation (47) reduces to the following expressions:

At the face of bridge:

$$m' = \frac{\varepsilon'^2 m_z}{b} \ldots\ldots\ldots\ldots (48)$$

At any other point of the section:

$$m' = \frac{\varepsilon' m_v}{b} \ldots\ldots\ldots\ldots (49)$$

Equation (49), like Equation (44), holds only for large ratios of $\frac{b}{t}$ $\left(\text{that is, } \frac{b}{t} > 3\right)$, which is usually the case for arches.

Radial Shear on Plane Perpendicular to Z-Axis.—From Fig. 16(*b*), since $\Sigma U = 0$ for equilibrium:

$$V' = \frac{\delta t_u}{\delta v} \left(\frac{a}{A}\right) + \varepsilon' \frac{t_u}{b} + \int_z^{\frac{b}{2}} \int_{-\frac{t}{2}}^{\frac{t}{2}} \frac{\delta t_3}{\delta v}\, dz\, du + \varepsilon' \int_{-\frac{t}{2}}^{\frac{t}{2}} t_3\, du \ldots (50)$$

At the face of bridge:

$$V' = \varepsilon' \frac{t_u}{b} - \frac{8}{5}\, \varepsilon' \frac{(m_v - \varepsilon' m_z)}{b\, t} \ldots\ldots\ldots\ldots (51)$$

At any other point of the section:

$$V' = \varepsilon' \frac{t_u}{b} \ldots\ldots\ldots\ldots (52)$$

SECTION 2.—MAXIMUM STRESSES AND TRANSFORMATION FORMULAS

In the design of a right rigid frame in which the fiber stresses produced by the moments are large compared to those produced by the direct thrusts, the live load thrusts are found with the live load in the position to produce maximum moments. The error involved is small. The same condition holds true in a skew arch, except that there are two moments, a thrust, and a shear: M_x, M_z, T_x, and T_z (or m_v, m_z, t_v, and t_z), that must be computed for the same position of live load instead of the single moment and thrust in the right arch and the position of the live load is governed by M_z. The problem of vertical shear or, more accurately, the radial shear, is treated in the same manner as in the right arch and needs no special consideration.

The maximum stresses for any given condition of loading occur on the principal planes. Steel can be designed in any direction to take care of the principal stresses, but if it were placed in one direction only, it would not resist the tension on a plane parallel to itself. Hence, the steel must be placed in two directions. However, while both sets of steel resist the tension on the principal planes, only one set acts on the plane parallel to the other. Therefore, more steel may be required on a plane parallel to one set of steel than on the principal planes. Reinforcement should be designed on the planes parallel to the direction of the steel, and also on the principal planes. Furthermore, the maximum horizontal shear will occur on still another plane. In order to analyze the stresses on these various planes, the stresses on a section must be transformed to give other stresses which are parallel and perpendicular to the planes in question.

The required transformation formulas can be obtained from any textbook on mechanics. They are given without proof in Appendix I in terms of the notation already adopted.

SECTION 3.—EFFECT OF ANGLE BETWEEN DIRECTION OF STEEL AND DIRECTION OF STRESS

It was shown in Section 2, that the directions of the principal stresses (which are the maximum and the minimum), with respect to the direction of the center line of the arch, are determined by the relative magnitudes of the forces acting on a section. While the direction of the stress varies, it is not practical to vary the direction of the steel. The angle made by the steel with the direction of the design stresses introduces certain factors which must be taken into account.

Before going further, it is well to point out the following more or less obvious fact. A steel reinforcing rod can take practically no bending. In tension, therefore, it acts like a string. If the stresses at a point are analyzed on different planes, the stress in the concrete will vary, but that in the steel at any point must remain constant. In other words, at a given point, the value, $f_s\ A_s$, is constant (for the same condition of loading) no matter on what plane the stresses are analyzed.

(*A*) Relation of Stress in Steel to Components of Direct Stress Deformation

In Fig. 17, *A D B F* is an element of concrete with a strand of reinforcing steel, *A B*, embedded in it. Forces producing tension and compression are acting on the four faces, *A D*, *B F*, *B D*, and *A F*, of the element so that it deflects in both directions. Point *A* is taken as the origin so that *B H* and *B G* are deflections for the lengths, *A F* and *B F*. Point *B* moves to *B′*, and the new length of the strand is now *A B′*.

From Fig. 17, since Angle $B\,A\,M$ is small and $A\,B = A\,M$, Angle $B\,M\,A$ may be considered a right angle. Let δ_1 be the unit elongation in the direction, $A\,F$; δ_2, the unit elongation in the direction, $B\,F$; and, f_d, the stress in the steel due to the direct stresses in the concrete. Then,

$$\delta_1 = \frac{B\,H}{B\,D} = \frac{B\,B' \cos \beta}{A\,B \cos \alpha} = \frac{B'\,M \sec (\alpha - \beta) \cos \beta}{A\,B \cos A}$$

or,

$$\delta_1 = \frac{f_d}{E_s} \, \frac{\cos \beta}{\cos \alpha \cos (\alpha - \beta)} \quad \text{(54)}$$

Also,

$$\delta_2 = \frac{B\,G}{B\,F} = \frac{B\,B' \sin \beta}{A\,B \sin \alpha} = \frac{B'\,M \sin \beta}{A\,B \sin \alpha \cos (\alpha - \beta)}$$

or,

$$\delta_2 = \frac{f_d}{E_s} \, \frac{\sin \beta}{\sin \alpha \cos (\alpha - \beta)} \quad \text{(55)}$$

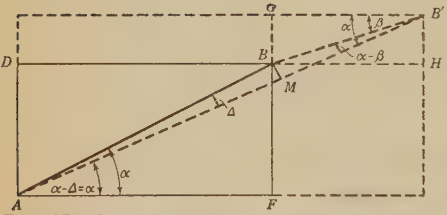

FIG. 17.—DEFORMATION IN STEEL PRODUCED BY DIRECT DEFORMATION.

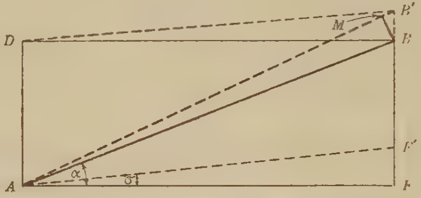

FIG. 18.—DEFORMATION IN STEEL PRODUCED BY SHEAR DEFORMATION IN CONCRETE.

Dividing Equation (54) by Equation (55), $\dfrac{\delta_1}{\delta_2} = \dfrac{\tan \alpha}{\tan \beta}$, or,

$$\tan \beta = \frac{\delta_2}{\delta_1} \tan \alpha \quad \text{(56)}$$

From Equation (54)

$$\delta_1 = \frac{f_d}{E_s \cos \alpha (\cos \alpha + \sin \alpha \tan \beta)} \quad \text{(57)}$$

Substituting Equation (56) in Equation (57), and transforming:

$$\frac{f_d}{E_s} = \delta_1 \cos^2 \alpha + \delta_2 \sin^2 \alpha \quad \text{(58)}$$

(B) Relation of Stresses in Steel to Shear Deformation

From Fig. 18, neglecting the squares of small quantities: $(A\,M + B'\,M)^2 = (A\,F)^2 + (B\,F + B\,B')^2$, or $F\,F' = \dfrac{B'\,M \times A\,M}{B\,F}$. Writing for $F\,F'$ its value, $A\,F \times \sigma$, and assuming that f_v equals the stress in the steel due to the shear in the concrete; then, $\sigma = \dfrac{B'\,M}{A\,F} \times \dfrac{A\,M}{B\,F} = \dfrac{B'\,M}{A\,B \cos \alpha} \times \dfrac{1}{\sin \alpha}$. Therefore,

$$\frac{f_v}{E_s} = \sigma \sin \alpha \cos \alpha \quad \text{(59)}$$

Combining Equations (58) and (59) to get the total stress in the steel,

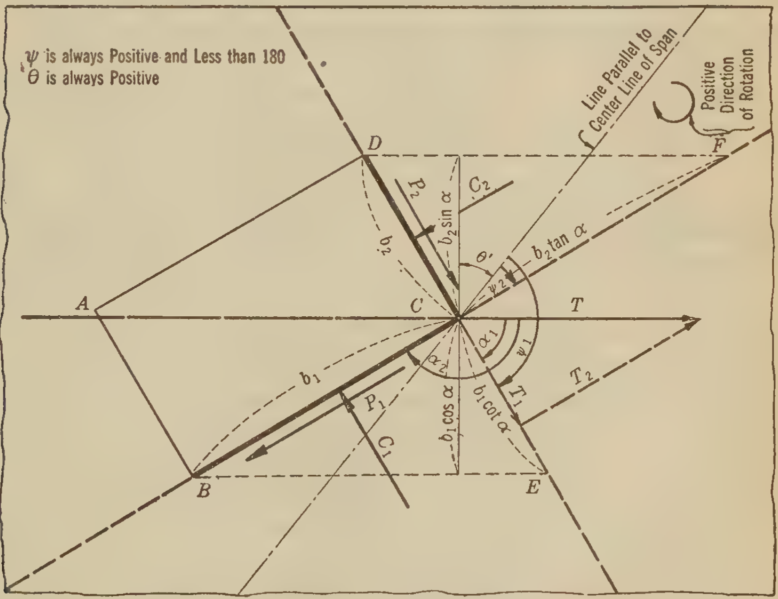
$$\frac{f_s}{E_s} = \delta_1 \cos^2 \alpha + \delta_2 \sin^2 \alpha + \sigma \sin \alpha \cos \alpha \ldots\ldots\ldots\ldots (60)$$

Equation (60) gives the relation between the stress in the steel, the components of the elongation of the steel in the direction of the direct stresses on the faces of the concrete element, and the shearing deformation of that element.

In the usual simple case where the steel is parallel to the direction of the applied stress, the deformations in the steel and in the concrete are proportional to their distances from the neutral axis. In the present case, the components of the deformations in the steel and in the concrete in the same direction are proportional to their distances from their respective neutral axes.

Section 4.—Derivation of Design Formulas

The design formulas can be divided into twelve cases, each one of which has three sub-divisions. Each of these sets of formulas can be tabulated. The method of deriving the formulas is explained in detail for Case I in the discussion which follows.



ψ is always Positive and Less than 180
θ is always Positive
Line Parallel to Center Line of Span
Positive Direction of Rotation
D
F
C₂
P₂
b₂ sin α
b₂
θ'
b₂ tan α

E

Fig. 19.—Diagram Showing Design Planes.

Case I.—Simple Bending—Steel in One Direction and in One Face Only

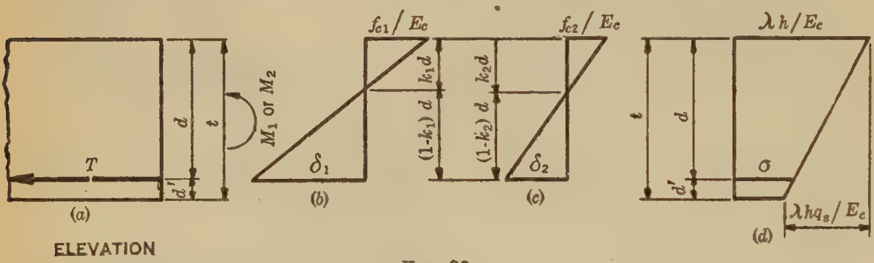
In Fig. 19, $A\,B\,C\,D$ is an element of concrete of small dimensions in which a strand of steel is embedded. The planes, $B\,C\,F$ and $D\,C\,E$, are any two planes at right angles and will be referred to as "Design Planes". The subscript numeral, 1, is attached to all symbols on the plane, $B\ C\ F$, and the subscript numeral, 2, to all symbols on the plane, $D\ C\ E$.

The values of α for various conditions are:

Longitudinal steel, parallel to fascia	$(\psi + \theta') - 90°$
Longitudinal steel, perpendicular to abutment	$\psi - 90°$
Cross-steel, perpendicular to fascia	$\psi + \theta'$
Cross-steel, parallel to abutments	ψ

In the following derivations, Poisson's ratio is neglected because the value of this modulus is about the same for both concrete and steel. Poisson's ratio affects only the relative deformations and, since the value is about the same for both materials, there is no differential action on this account, and, therefore, no change in the relative stresses is produced. The stress deformation diagrams for each design plane are drawn as if there were no stress on the plane at right angles to it. The deformations shown are, therefore, only those produced by the stresses acting on the plane in question.

(*A*).—*Tension Over Part of Section on Both Design Planes and on the Same Side of the Section.*—For this case, assuming the usual straight-line distribution of flexural stress, the stress deformation diagrams on Planes $B\ C\ F$ and $D\ C\ E$, Fig. 19, are shown in Fig. 20(*b*) and Fig. 20(*c*). At the middle of the cross-section, the torsion moment stresses also have a straight-line distribution, and the resulting stress deformation diagram, taking into account the shear produced by the angularity of the steel, is as shown in Fig. 20(*d*).



ELEVATION

FIG. 20.

From Figs. 19 and 20:

$$\left.\begin{aligned} T &= f_s\,A_s\,(b_1 \cos \alpha_1 + b_2 \sin \alpha_1) \\ T_1 &= T \cos \alpha_1 = \begin{cases} \text{tension over } B\ F \\ \text{shear over } D\ E \end{cases} \\ T_2 &= T \sin \alpha_1 = \begin{cases} \text{tension over } D\ E \\ \text{shear over } B\ F \end{cases} \end{aligned}\right\} \quad \ldots\ldots\ldots\ldots (61a)$$

$$\left.\begin{aligned} C_1 &= \frac{1}{2} f_{c1}\,k_1\,b_1\,d \\ C_2 &= \frac{1}{2} f_{c2}\,k_2\,b_2\,d \end{aligned}\right\} \quad \ldots\ldots\ldots\ldots (61b)$$

$$\left.\begin{aligned} P_1 &= \frac{1}{2} h_1\,(2 - q)\,b_1\,t \\ P_2 &= \frac{1}{2} h_2\,(2 - q)\,b_2\,t \end{aligned}\right\} \quad \ldots\ldots\ldots\ldots (61c)$$

On Plane $B\,C$, since the summation of all forces parallel and perpendicular to the plane must be zero for equilibrium:

$$\left.\begin{aligned} \frac{C_1}{b_1} &= \frac{T_1}{b_1 + b_2 \tan \alpha_1} \\ \frac{P_1}{b_1} &= \frac{T_2}{b_1 + b_2 \tan \alpha_1} \end{aligned}\right\} \cdots\cdots\cdots\cdots (61d)$$

Similarly, on Plane $C\,D$:

$$\left.\begin{aligned} \frac{C_2}{b_2} &= \frac{T_2}{b_1 \cot \alpha_1 + b_2} \\ \frac{P_2}{b_2} &= \frac{T_2}{b_1 \cot \alpha_1 + b_2} \end{aligned}\right\} \cdots\cdots\cdots\cdots (61e)$$

Substituting the values from Equations (61*a*), (61*b*), and (61*c*) in Equations (61*d*) and (61*e*), and writing $p\,d$ for A_s:

$$\left.\begin{aligned} f_s\,p \cos^2 \alpha_1 &= \frac{1}{2} f_{c1}\,k_1 \\ f_s\,p \sin^2 \alpha_1 &= \frac{1}{2} f_{c2}\,k_2 = f_s\,p \cos^2 \alpha_2 \\ f_s\,p \sin \alpha_1 \cos \alpha_1 &= \frac{1}{2} h_1 (2 - q_s) \frac{t}{d} = \frac{1}{2} h_2 (2 - q_s) \frac{t}{d} \\ f_s\,p \sin \alpha_2 \cos \alpha_2 &= \frac{1}{2} h_1 (2 - q_s) \frac{t}{d} = \frac{1}{2} h_2 (2 - q_s) \frac{t}{d} \end{aligned}\right\} \cdots (61f)$$

$$\left.\begin{aligned} M_1 &= \frac{1}{2} f_{c1}\,k_1\,j_1\,d^2 \\ M_2 &= \frac{1}{2} f_{c2}\,k_2\,j_2\,d^2 \\ M_s &= \frac{1}{2} h_1 (2 - q_s)\,j_s\,t^2 = \frac{1}{2} h_2 (2 - q_s)\,j_s\,t^2 \end{aligned}\right\} \cdots\cdots\cdots (61g)$$

$$\left.\begin{aligned} M_1 &= f_s\,p\,j_1\,d^2 \cos^2 \alpha_1 \\ M_2 &= f_s\,p\,j_2\,d^2 \sin^2 \alpha_1 = f_s\,p\,j_2\,d^2 \cos^2 \alpha_2 \\ M_s &= f_s\,p\,j_s\,dt \sin \alpha_1 \cos \alpha_1 = f_s\,p\,j_s\,d\,t \sin \alpha_2 \cos \alpha_2 \end{aligned}\right\} \cdots\cdots (61h)$$

$$\left.\begin{aligned} j_1 &= 1 - \frac{k_1}{3} \\ j_2 &= 1 - \frac{k_2}{3} \\ j_s &= \frac{d}{t} - \frac{3 - 2\,q_s}{6 - 3\,q_s} \end{aligned}\right\} \cdots\cdots\cdots\cdots (61i)$$

From Fig. 20:

$$\left.\begin{aligned} \delta_1 &= \frac{f_{c1}}{E_c} \left(\frac{1 - k_1}{k_1}\right) \\ \delta_2 &= \frac{f_{c2}}{E_c} \left(\frac{1 - k_2}{k_2}\right) \\ \sigma &= - \frac{\lambda\,h_1}{E_c} \left(1 - q\,\frac{d}{t}\right) \end{aligned}\right\} \cdots\cdots\cdots\cdots (61j)$$

Substituting the values from Equations (61*j*) in Equation (60):

$$\left.\begin{aligned}\frac{f_s}{n} &= f_{c1}\left(\frac{1-k_1}{k_1}\right)\cos^2\alpha_1 + f_{c2}\left(\frac{1-k_2}{k_2}\right)\sin^2\alpha_1 - \lambda\,h_1\left(1-q_s\frac{d}{t}\right)\sin\alpha_1\cos\alpha_1\\ \frac{f_s}{n} &= f_{c1}\left(\frac{1-k_1}{k_1}\right)\sin^2\alpha_2 + f_{c2}\left(\frac{1-k_2}{k_2}\right)\cos^2\alpha_2 - \lambda\,h_2\left(1-q_s\frac{d}{t}\right)\sin\alpha_2\cos\alpha_2\end{aligned}\right\}\text{(61}k\text{)}$$

Eliminating f_s, f_{c1}, and f_{c2} between Equations (61*f*) and Equations (61*k*):

$$\left.\begin{aligned}\frac{1}{2\,p\,n} &= \left(\frac{1-k_1}{k_1^{\,2}}\right)\cos^4\alpha_1 + \left(\frac{1-k_2}{k_2^{\,2}}\right)\sin^4\alpha_1\\ &\quad - \lambda\left(\frac{d}{t}\right)\left(\frac{1-q_s\dfrac{d}{t}}{2-q_s}\right)\sin^2\alpha_1\cos^2\alpha_1\\ \frac{1}{2\,p\,n} &= \left(\frac{1-k_1}{k_1^{\,2}}\right)\cos^4\alpha_1 + \left(\frac{1-k_2}{k_2^{\,2}}\right)\cos^4\alpha_2\\ &\quad - \lambda\left(\frac{d}{t}\right)\left(\frac{1-q_s\dfrac{d}{t}}{2-q_s}\right)\sin^2\alpha_2\cos^2\alpha_2\end{aligned}\right\}\ldots\ldots\ldots\text{(61}l\text{)}$$

Also:

$$\begin{aligned}\frac{\cos^2\alpha_1\,f_s}{n\,f_{c1}\,k_1} &= \left(\frac{1-k_1}{k_1^{\,2}}\right)\cos^4\alpha_1 + \left(\frac{1-k_2}{k_2^{\,2}}\right)\sin^4\alpha_1\\ &\quad - \lambda\left(\frac{d}{t}\right)\left(\frac{1-q_s\dfrac{d}{t}}{2-q_s}\right)\sin^2\alpha_1\cos^2\alpha_1\ldots\ldots\ldots\ldots\ldots\text{(61}m\text{)}\end{aligned}$$

$$\left.\begin{aligned}j_2 &= \left(\frac{M_2}{M_1}\right)\left(\frac{j_1}{\tan^2\alpha}\right)\\ j_s &= \left(\frac{M_s}{M_1}\right)\left(\frac{d}{t}\right)\left(\frac{j_1}{\tan\alpha}\right)\end{aligned}\right\}\ldots\ldots\ldots\ldots\ldots\ldots\ldots\text{(61}n\text{)}$$

$$\left.\begin{aligned}k_2 &= 3\,(1-j_2)\\ q_s &= \frac{3+6\,j_s-6\,\dfrac{d}{t}}{2+3\,j_s-3\,\dfrac{d}{t}}\end{aligned}\right\}\ldots\ldots\ldots\ldots\ldots\ldots\ldots\text{(61}p\text{)}$$

If the design planes are principal planes:

$$\left.\begin{aligned}M_s &= 0\\ j_s &= 0\\ q_s &= \frac{6\,\dfrac{d}{t}-3}{3\,\dfrac{d}{t}-2}\end{aligned}\right\}\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\text{(61}q\text{)}$$

(*B*).—*Tension Over Part of Section on One Design Plane, Compression Over Entire Section on the Other Design Plane.*—In Fig. 21(*a*) is shown a section of a reinforced concrete beam on which a moment, M_2, is acting. The usual stress-strain diagram for this case is shown in Fig. 21(*b*). The stress in the concrete acting with the stress in the steel produces a couple which balances the applied couple, M_2; but if there should be an initial tension in the steel, this stress (which is eccentric to the section), produces a moment which partly counteracts the applied couple, and at the same time produces a direct compressive stress on the section. Under certain conditions it may produce compression over the entire section as shown in Fig. 21(*c*). If the moment of the initial stress about the center of the section should happen to equal the applied moment, then the compression is uniformly distributed over the section, as shown in Fig. 21(*d*). If the initial stress moment is larger than the applied couple, the stress distribution may be as shown in Fig. 21(*e*).

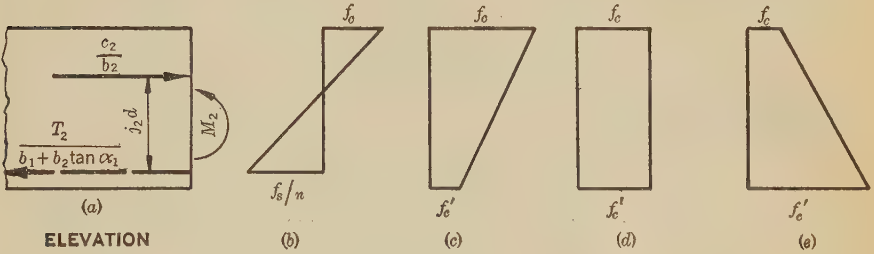


FIG. 21.

Since (as shown in Case I(*A*)), the stress in the steel is produced by moments on two planes, it may so happen that the moment of steel stress component on a plane may be greater than the applied couple and cause a kind of reversal of stress. The result will be similar to the case of initial stress just discussed. Case I(*A*) will fail when either value of k is greater than unity. For this contingency, Case I(*B*), or one of the following cases, must be used.

Referring to Fig. 19, the state of stress is assumed to be such that the stress-strain distribution on Plane *B C* is as shown in Fig. 22(*b*), and that on Plane *C D*, as shown in Fig. 22(*d*).

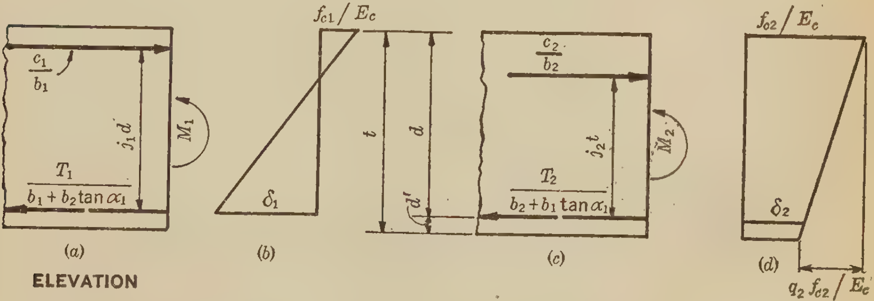

FIG. 22.

From Fig. 19 and Fig. 22:

$$\left.\begin{aligned} T &= f_s\,A_s\,(b_1 \cos \alpha_1 + b_2 \sin \alpha_1) \\ T_1 &= T \cos \alpha_1 \\ T_2 &= T \sin \alpha_1 \end{aligned}\right\} \qquad (62a)$$

$$\left.\begin{aligned} C_1 &= \frac{1}{2} f_{c1}\, k_1\, b_1\, d \\ C_2 &= \frac{1}{2} f_{c2}\, (2 - q_2)\, b_2\, t \end{aligned}\right\} \dots\dots\dots\dots\dots\dots (62b)$$

$$\left.\begin{aligned} P_1 &= \frac{1}{2} h_1\, (2 - q_s)\, b_1\, t \\ P_2 &= \frac{1}{2} h_2\, (2 - q_s)\, b_2\, t \end{aligned}\right\} \dots\dots\dots\dots\dots\dots (62c)$$

On Plane $B\,C\,F$:

$$\left.\begin{aligned} \frac{C_1}{b_1} &= \frac{T_1}{b_1 + b_2 \tan \alpha_1} \\ \frac{P_1}{b_1} &= \frac{T_2}{b_1 + b_2 \tan \alpha_1} \end{aligned}\right\} \dots\dots\dots\dots\dots\dots (62d)$$

On Plane $D\,C\,E$:

$$\left.\begin{aligned} \frac{C_2}{b_2} &= \frac{T_2}{b_1 \cot \alpha_1 + b_2} \\ \frac{P_2}{b_2} &= -\frac{T_1}{b_1 \cot \alpha_1 + b_2} \end{aligned}\right\} \dots\dots\dots\dots\dots\dots (62e)$$

$$\left.\begin{aligned} f_s\, p \cos^2 \alpha_1 &= \frac{1}{2} f_{c1}\, k_1 \\ f_s\, p \sin^2 \alpha_1 &= \frac{1}{2} f_{c2}\, (2 - q_2) \frac{t}{d} = f_s\, p \cos^2 \alpha_2 \\ f_s\, p \sin \alpha_1 \cos \alpha_1 &= \frac{1}{2} h_1\, (2 - q_s) \frac{t}{d} = \frac{1}{2} h_2\, (2 - q_s) \frac{t}{d} \\ f_s\, p \sin \alpha_2 \cos \alpha_2 &= \frac{1}{2} h_1\, (2 - q_s) \frac{t}{d} = \frac{1}{2} h_2\, (2 - q_s) \frac{t}{d} \end{aligned}\right\} \dots (62f)$$

$$\left.\begin{aligned} M_1 &= \frac{1}{2} f_{c1}\, k_1\, j_1\, d^2 \\ M_2 &= \frac{1}{2} f_{c2}\, (2 - q_2)\, j_2\, t^2 \\ M_s &= \frac{1}{2} h\, (2 - q_s)\, j_s\, t^2 \end{aligned}\right\} \dots\dots\dots\dots\dots\dots (62g)$$

$$\left.\begin{aligned} M_1 &= f_s\, p\, j_1\, d^2 \cos^2 \alpha_1 \\ M_2 &= f_s\, p\, j_2\, d\, t \sin^2 \alpha_1 = f_s\, p\, j_2\, d\, t \cos^2 \alpha_2 \\ M_s &= f_s\, p\, j_s\, d\, t \sin \alpha_1 \cos \alpha_1 = f_s\, p\, j_s\, d\, t \sin \alpha_2 \cos \alpha_2 \end{aligned}\right\} \dots\dots (62h)$$

$$\left.\begin{aligned} j_1 &= 1 - \frac{k_1}{3} \\ j_2 &= \frac{d}{t} - \frac{3 - 2\, q_2}{6 - 3\, q_2} \\ j_s &= \frac{d}{t} - \frac{3 - 2\, q_s}{6 - 3\, q_s} \end{aligned}\right\} \dots\dots\dots\dots\dots\dots (62i)$$

From Figs. 20 and 22:

$$\left.\begin{aligned} \delta_1 &= \frac{f_{c1}}{E_c}\left(\frac{1-k_1}{k_1}\right) \\ \delta_2 &= -\frac{f_{c2}}{E_c}\left(1-q_2\frac{d}{t}\right) \\ \sigma &= -\frac{\lambda h}{E_c}\left(1-q_s\frac{d}{t}\right) \end{aligned}\right\}\dots\dots(62j)$$

Substituting Equations (62*j*) in Equation (60):

$$\left.\begin{aligned} \frac{f_s}{n} &= f_{c1}\left(\frac{1-k_1}{k_1}\right)\cos^2\alpha_1 - f_{c2}\left(1-q_2\frac{d}{t}\right)\sin^2\alpha_1 - \lambda h_1\left(1-q_s\frac{d}{t}\right)\sin\alpha_1\cos\alpha_1 \\ \frac{f_s}{n} &= f_{c1}\left(\frac{1-k_1}{k_1}\right)\sin^2\alpha_2 - f_{c2}\left(1-q_2\frac{d}{t}\right)\cos^2\alpha_2 - \lambda h_2\left(1-q_s\frac{d}{t}\right)\sin\alpha_2\cos\alpha_2 \end{aligned}\right\}(62k)$$

Eliminating f_s, f_{c1}, and f_{c2} between Equations (62*f*) and (62*k*):

$$\left.\begin{aligned} \frac{1}{2\,p\,n} &= \left(\frac{1-k_1}{k_1{}^2}\right)\cos^4\alpha_1 - \left(\frac{d}{t}\right)\left(\frac{1-q_2\dfrac{d}{t}}{2-q_2}\right)\sin^4\alpha_1 \\ &\quad - \lambda\frac{d}{t}\left(\frac{1-q_2\dfrac{d}{t}}{2-q_s}\right)\sin^2\alpha_1\cos^2\alpha_1 \\ \frac{1}{2\,p\,n} &= \left(\frac{1-k_1}{k_1{}^2}\right)\sin^4\alpha_2 - \left(\frac{d}{t}\right)\left(\frac{1-q_2\dfrac{d}{t}}{2-q_2}\right)\cos^4\alpha_2 \\ &\quad - \lambda\left(\frac{d}{t}\right)\left(\frac{1-q_s\dfrac{d}{t}}{2-q_s}\right)\sin^2\alpha_2\cos^2\alpha_2 \end{aligned}\right\}\dots\dots(62l)$$

Also:

$$\begin{aligned} \frac{\cos^2\alpha_1\,f_s}{n\,f_{c1}\,k_1} &= \left(\frac{1-k_1}{k_1{}^2}\right)\cos^4\alpha_1 - \frac{d}{t}\left(\frac{1-q_2\dfrac{d}{t}}{2-q_2}\right)\sin^4\alpha_1 \\ &\quad - \lambda\left(\frac{d}{t}\right)\left(\frac{1-q_s\dfrac{d}{t}}{2-q_s}\right)\sin^2\alpha_1\cos^2\alpha_1\dots\dots(62m) \end{aligned}$$

$$\left.\begin{aligned} j_2 &= \left(\frac{d}{t}\right)\left(\frac{M_2}{M_1}\right)\left(\frac{j_1}{\tan^2\alpha}\right) \\ j_s &= \left(\frac{d}{t}\right)\frac{M_s}{M_1}\,\frac{j_1}{\tan\alpha_1} \end{aligned}\right\}\dots\dots(62n)$$

$$\left.\begin{aligned} q_2 &= \frac{3+6\,j_2-6\dfrac{d}{t}}{2+3\,j_2-3\dfrac{d}{t}} \\ q_s &= \frac{3+6\,j_s-6\dfrac{d}{t}}{2+3\,j_s-3\dfrac{d}{t}} \end{aligned}\right\}\dots\dots(62p)$$

If the design planes are principal planes:

$$\left.\begin{aligned} M_s &= 0 \\ j_s &= 0 \\ q_s &= \frac{6\,\dfrac{d}{t} - 3}{3\,\dfrac{d}{t} - 2} \end{aligned}\right\} \quad \text{(62}q\text{)}$$

(*C*).—*Tension Over Part of Section on Both Design Planes But on Opposite Sides of Section.*—This case may arise in two ways: (1) recalling the discussion of Case I(*B*), if the initial tension moment is greater than the applied moment and produces a reversal of stress such that the resultant falls outside the middle third of the section; and (2) if the moments on both design planes are of opposite signs. If tension is allowed in the concrete, Case I (*B*) governs, q_2 will be greater than unity, and f_{c2} will be negative. If no tension is allowed in the concrete, or if it exceeds the allowable value, then Case I (*C*) must be used.

In Case I (*C*), the resultant of the compressive stresses falls outside the middle third and nominal steel should be used in the tension area. If f_{c2} is too high, Case II (*A*), or one of the following cases, will apply.

Fig. 23 shows the stress deformation diagram for the design plane on which there is tension over the extrados part of the section. The other diagrams are the same as in Figs. 21 and 22 and are not shown.

It will be noticed that Equations (62) are derived in the same way as Equations (61) and that the only differences between the corresponding equations are in the values of k, q, j, and in the expressions involving these symbols. The same thing is true for Equations (63) and the detailed derivation is not given:

$$\left.\begin{aligned} f_s\,p\cos^2\alpha_1 &= \frac{1}{2} f_{c1}\,k_1 \\ f_s\,p\sin^2\alpha_1 &= \frac{1}{2} f_{c2}\,k_2 = f_s\,p\cos^2\alpha_2 \\ f_s\,p\sin\alpha_1\cos\alpha_1 &= \frac{1}{2} h_1\,(2 - q_s)\,\frac{t}{d} = \frac{1}{2} h_2\,(2 - q_s)\,\frac{t}{d} \\ f_s\,p\sin\alpha_2\cos\alpha_2 &= +\frac{1}{2} h_1\,(2 - q_s)\,\frac{t}{d} = \frac{1}{2} h_2\,(2 - q_s)\,\frac{t}{d} \end{aligned}\right\} \quad \text{(63}f\text{)}$$

$$\left.\begin{aligned} M_1 &= \frac{1}{2} f_{c1}\,k_1\,j_1\,d^2 \\ M_2 &= \frac{1}{2} f_{c2}\,k_2\,j_2\,d^2 \\ M_s &= \frac{1}{2} h_1\,(2 - q_s)\,j_s\,t^2 = \frac{1}{2} h_2\,(2 - q_s)\,j_s\,t^2 \end{aligned}\right\} \quad \text{(63}g\text{)}$$

$$\left.\begin{aligned} M_1 &= f_s\,p\,j_1\,d^2\cos^2\alpha_1 \\ M_2 &= f_s\,p\,j_2\,d^2\sin^2\alpha_1 = f_s\,p\,j_2\,d^2\cos^2\alpha_2 \\ M_s &= f_s\,p\,j_s\,d\,t\sin\alpha_1\cos\alpha_1 = f_s\,p\,j_s\,d\,t\sin\alpha_2\cos\alpha_2 \end{aligned}\right\} \quad \text{(63}h\text{)}$$

$$\left.\begin{aligned} j_1 &= 1 - \frac{k_1}{3} \\ j_2 &= \frac{k_2}{3} - \frac{d'}{d} \\ j_s &= \frac{d}{t} - \frac{3 - 2\,q_s}{6 - 3\,q_s} \end{aligned}\right\} \cdots\cdots\cdots\cdots (63i)$$

From Fig. 20:

$$\left.\begin{aligned} \delta_1 &= \frac{f_{c1}}{E_c}\left(\frac{1 - k_1}{k_1}\right) \\ \delta_2 &= \frac{f_{c2}}{E_c}\left(\frac{k_2 - \dfrac{d'}{d}}{k_2}\right) \\ \sigma &= -\frac{\lambda\,h}{E_c}\left(1 - q_s\,\frac{d}{t}\right) \end{aligned}\right\} \cdots\cdots\cdots\cdots (63j)$$

$$\left.\begin{aligned} \frac{f_s}{n} &= f_{c1}\left(\frac{1 - k_1}{k_1}\right)\cos^2\alpha_1 - f_{c2}\left(\frac{k_2 - \dfrac{d'}{d}}{k_2}\right)\sin^2\alpha_1 \\ &\qquad - \lambda\,h_1\left(1 - q_s\,\frac{d}{t}\right)\sin\alpha_1\cos\alpha_1 \\ \frac{f_s}{n} &= f_{c1}\left(\frac{1 - k_1}{k_1}\right)\sin^2\alpha_2 - f_{c2}\left(\frac{k_2 - \dfrac{d'}{d}}{k_2}\right)\cos^2\alpha_2 \\ &\qquad - \lambda\,h_2\left(1 - q_s\,\frac{d}{t}\right)\sin\alpha_2\cos\alpha_2 \end{aligned}\right\} \cdots\cdots (63k)$$

$$\left.\begin{aligned} \frac{1}{2\,p\,n} &= \left(\frac{1 - k_1}{{k_1}^2}\right)\cos^4\alpha_1 - \left(\frac{k_2 - \dfrac{d'}{d}}{{k_2}^2}\right)\sin^4\alpha_1 \\ &\qquad - \lambda\left(\frac{d}{t}\right)\left(\frac{1 - q\,\dfrac{d}{t}}{2 - q_s}\right)\sin^2\alpha_1\cos^2\alpha_1 \\ \frac{1}{2\,p\,n} &= \left(\frac{1 - k_1}{{k_1}^2}\right)\sin^4\alpha_2 - \left(\frac{k_2 - \dfrac{d'}{d}}{{k_2}^2}\right)\cos^4\alpha_2 \\ &\qquad - \lambda\left(\frac{d}{t}\right)\left(\frac{1 - q_s\,\dfrac{d}{t}}{2 - q_s}\right)\sin^2\alpha_2\cos^2\alpha_2 \end{aligned}\right\} \cdots\cdots (63l)$$

Also,

$$\left.\begin{aligned} \frac{\cos^2\alpha_1\,f_s}{n\,f_{c1}\,k_1} &= \left(\frac{1 - k_1}{{k_1}^2}\right)\cos^4\alpha_1 - \left(\frac{k_2 - \dfrac{d'}{d}}{{k_2}^2}\right)\sin^4\alpha_1 \\ &\qquad - \lambda\left(\frac{d}{t}\right)\left(\frac{1 - q_s\,\dfrac{d}{t}}{2 - q_s}\right)\sin^2\alpha_1\cos^2\alpha_1 \end{aligned}\right\} \cdots\cdots (63m)$$

$$\left.\begin{aligned} j_2 &= \left(\frac{M_2}{M_1}\right)\frac{j_1}{\tan^2 \alpha_1} \\ j_s &= \left(\frac{d}{t}\right)\left(\frac{M_s}{M_1}\right)\frac{j_1}{\tan \alpha_1} \end{aligned}\right\} \qquad (63n)$$

$$\left.\begin{aligned} k_2 &= 3\left(j_2 + \frac{d'}{d}\right) \\ q_s &= \frac{3 + 6\, j_s - 6\,\dfrac{d}{t}}{2 + 3\, j_s - 3\,\dfrac{d}{t}} \end{aligned}\right\} \qquad (63p)$$

If the design planes are principal planes:

$$\left.\begin{aligned} M_s &= 0 \\ j_s &= 0 \\ q_s &= \frac{6\,\dfrac{d}{t} - 3}{3\,\dfrac{d}{t} - 2} \end{aligned}\right\} \qquad (63q)$$

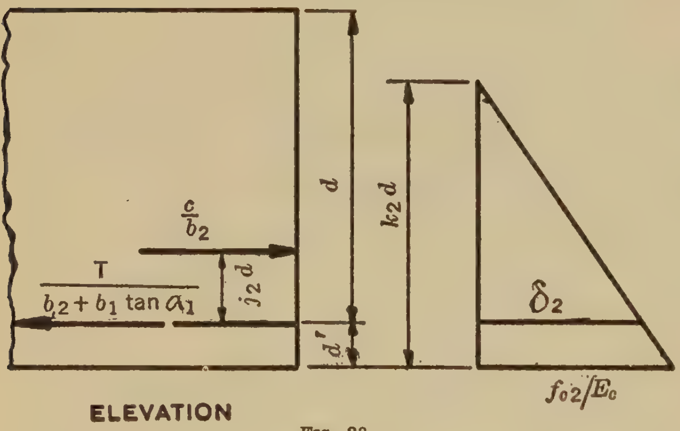

FIG. 23.

SECTION 5.—FINAL DESIGN FORMULAS

Section 4 shows the method of deriving the design formulas. In general, the stress in a strand of steel at an angle to a plane is produced by the forces acting on the plane in question and also by the forces acting on the plane at right angles to it. Furthermore, even the concrete stresses on a plane are partly dependent on the forces acting on the plane at right angles to it, and which are transmitted to it by the steel. Since two planes at right angles to each other must be analyzed together, many combinations of stress conditions on the two design planes are possible. If there are n stress conditions possible on a plane, there must be n^2 possible combinations when two planes are treated together. Hence, there would be a large number of cases to be analyzed if the design formulas were written according to the method used in the Section 4.

It is apparent from a study of Section 4, that the two design planes can be treated independently, except for the equations, (k), (l), and (m). There is, however, a certain symmetry about all the equations which makes it possible to treat each design plane independently and thus greatly reduce the number of cases to be analyzed. To analyze the stresses for any given set of conditions, the proper set of formulas for one design plane is combined with the proper set for the other plane. For brevity these formulas are tabulated and placed in Appendix I under the caption, "Equation (64)," in order to help the designer in referring back to the text when necessary.

Example 2.—Proportioning of Sections

Part I concluded with a numerical example which was carried up to the point at which the maximum moments, thrusts, and shears were obtained. Numerical Example 1 will now be resumed and several sections designed, thus illustrating the application of the design formulas which have been developed in Part II.

Design of Steel at Crown ($x = 0$)

$$\left.\begin{array}{l} M_x = 741 \text{ kip-ft.} \\ T_z = 452 \text{ kips} \end{array}\right\} \quad \left.\begin{array}{l} M_z = 1\,509 \text{ kip-ft.} \\ T_x = 418 \text{ kips} \end{array}\right\} \quad \left.\begin{array}{l} t = 21 \text{ in.} \\ d = 18.5 \text{ in.} \end{array}\right\} \quad \left.\begin{array}{l} \varepsilon = 1.192 \\ \varepsilon^2 = 1.420 \end{array}\right\}$$

$$\left.\begin{array}{l} m = \dfrac{1\,509}{66.9} = 22.5 \text{ kip-ft.} \\[2ex] t_n = \dfrac{418}{66.9} = 6.25 \text{ kips} \end{array}\right\}$$

Fascia Steel.—

$$\left.\begin{array}{l} M = m \sec^2 \theta' \text{ (See Equation (53}d\text{), Appendix I} \\ N = t_n \sec^2 \theta' \text{ (See Equation (53}f\text{), Appendix I} \end{array}\right\} \text{and } \theta' = \theta$$

$$N = 6.25 \times 2.42 = 15.13 \text{ kips}$$

$$e = \frac{22.5}{6.25} \times 12 + 8.0 = 51.1 \text{ in.}$$

$$r = 16.0$$

$$e - r = 35.1 \text{ in.}$$

$$\frac{e}{d} = \frac{51.1}{18.5} = 2.76$$

$$K = \frac{N\,e}{b\,d^2} = \frac{15.13 \times 2.76}{12 \times 18.5} = 188$$

K (for tension steel only) $= 138$ (for $f_c = 800, f_s = 18\,000, n = 15$)

$$N' = \left(\frac{188 - 138}{188}\right) \times 15.13 = 4.03 \text{ kips}$$

$$f'_s = \frac{k\,d - d'}{k\,d} \times n\,f_c = \left(\frac{0.400 \times 18.5 - 2.5}{0.400 \times 18.5}\right) \times 12\,000 = 7.95 \text{ kips}$$

$$A'_s = \frac{N'\,e}{f'_s\,r} = \frac{4.03 \times 51.1}{7.95 \times 16.0} = 1.62 \text{ sq. in.}$$

$$\left.\begin{array}{l} A_{s1} = \dfrac{N'\,(e - r)}{f_s\,r} = \dfrac{4.03 \times 35.1}{18.0 \times 16.0} = 0.49 \\[2ex] A_{s2} = 0.0059 \times 12 \times 18.5 = \quad 1.31\,\text{[8]} \end{array}\right\} 1.80 \text{ sq. in.}$$

---

[8] Hool and Johnson, p. 405.

The fascia section extends for a distance (parallel to the abutments) of about one and one-half times the depth of the section; and where cross-steel is required, it should extend for at least a bond length of the cross-steel.

Center Steel (Parallel and Perpendicular to Spandrel Walls).—

$$\frac{m_v}{b} = \frac{741}{66.9} = 11.1 \text{ kip-ft.}$$

$$\varepsilon' \, m = 22.5 \times 1.192 = 26.8$$

$$m_s = \frac{1}{2} \times \overline{37.9} = 19.0 \text{ kip-ft. (See Equation (44) Appendix I)}$$

$$m' = \frac{\varepsilon' \, m_v}{b} = 1.192 \times 11.1 = 13.2 \text{ kip-ft.}$$

$$\frac{t_z}{b} = \frac{452}{66.9} = 6.75 \text{ kips}$$

$$\begin{array}{r} \varepsilon' \, t_n = 1.192 \times 6.25 = 7.45 \text{ kips} \\ -\,0.70 \text{ kips} \\ -\,\underline{0.35} \text{ kips} \\ -\,1.05 \text{ kips} \\ \varepsilon' \, t_n = \underline{7.45} \text{ kips} \\ t_s = 6.40 \text{ kips} \\ \text{(See Equation (35), Appendix I)} \end{array} \left\{ \begin{array}{ll} m = 22.5 \text{ kip-ft.} & t_n = 6.25 \text{ kips} \\ m' = 13.2 \text{ kips} & t'_n = 7.63 \text{ kips} \\ m_s = 19.0 & t_s = 6.40 \text{ kips} \end{array} \right.$$

$$t'_n = \varepsilon' \, t_s = 1.192 \times 6.40 = 7.63 \text{ kips}$$

(*a*) Minimum Cross Steel.—

$$\psi = 180 - \theta'$$

$$\sin \theta' = 0.766 \quad \sin^2 \theta' = 0.587$$

$$\cos \theta' = 0.643 \quad \cos^2 \theta' = 0.413$$

$$\begin{array}{rrr} m \sin^2 \theta' = & 22.5 \times 0.587 = & 13.2 \\ m' \cos^2 \theta' = & 13.2 \times 0.413 = & 5.3 \\ -2\, m_s \sin \theta' \cos \theta' = & 37.9 \times 0.766 \times 0.643 = & \underline{-\,18.6} \\ & M = & 0 \end{array}$$

$$\begin{array}{rrr} t_n \sin^2 \theta' = & 6.25 \times 0.587 = & 3.7 \\ t'_n \cos^2 \theta' = & 7.63 \times 0.413 = & 3.2 \\ -\,2\, t_s \sin \theta' \cos \theta' = & 2 \times 6.40 \times 0.492 = & \underline{-\,6.4} \\ & N = & 0.5 \text{ kip (negligible)} \end{array}$$

The foregoing computations show that only nominal steel is required.

(*b*) Minimum Longitudinal Steel.—

$$\begin{array}{lr} m \cos^2 \theta' = 22.5 \times 0.413 = & 9.2 \\ m' \sin^2 \theta' = 13.2 \times 0.587 = & 7.8 \\ 2\, m_s \sin \theta' \cos \theta' & \underline{18.6} \\ & 35.6 \text{ kip-ft.} \end{array} \qquad \begin{array}{lr} t_n \cos^2 \theta' = 6.25 \times 0.413 = & 2.6 \\ t'_n \sin^2 \theta' = 7.63 \times 0.587 = & 4.5 \\ 2\, t_s \sin \theta' \cos \theta' = & \underline{6.4} \\ & 13.5 \text{ kips} \end{array}$$

$$e = \frac{35.6}{13.5} \times 12 + 8.0 = 39.7$$

$$\frac{e}{d} = \frac{39.7}{18.5} = 2.14$$

$$K = \frac{13.5 \times 2.14}{12 \times 18.5} = 130$$

$$f_c = 770 \text{ lb.}$$

$$f_s = 18\,000$$

$$p = 0.0050$$

$$A_s = 12 \times 18.5 \times 0.0050 = 1.11 \text{ sq. in.}$$

(*c*) Principal Planes.—

$$\tan 2\,\psi = \frac{2\,m_s}{m' - m} = -\frac{37.9}{9.2}$$

$$\tan\,(2\,\psi - 90) = \frac{9.2}{37.9} = 0.243$$

$$2\,\psi_1 - 90 = 13^\circ\,40'\,;\ \psi_1 = 51^\circ\,50'\,;\ \text{and}\ \alpha_1 = \psi_1 + \theta' - 90 = 11^\circ\,50'$$

$$\sin\psi_1 = 0.786 \quad \sin^2\psi_1 = 0.618$$

$$\cos\psi_1 = 0.618 \quad \cos^2\psi_1 = 0.382$$

$$\sin\psi_1\cos\psi_1 = 0.485$$

$$\begin{aligned}
m\sin^2\psi_1 &= 22.5 \times 0.618 = 13.90 \text{ kip-ft.}\\
m'\cos^2\psi_1 &= 13.2 \times 0.382 = 5.05\\
2\,m_s\sin\psi_1\cos\psi_1 &= 37.9 \times 0.485 = \underline{18.40}\\
M_1 &= 37.35 \text{ kip-ft.}
\end{aligned}$$

$$\begin{aligned}
t_n\sin^2\psi_1 &= 6.25 \times 0.618 = 3.86 \text{ kips}\\
t'_n\cos^2\psi_1 &= 7.63 \times 0.382 = 2.91\\
2\,t_s\sin\psi_1\cos\psi_1 &= 12.8 \times 0.485 = \underline{6.21}\\
N_1 &= 12.98 \text{ kips}
\end{aligned}$$

$$\begin{aligned}
m\sin^2\psi_2 &= 22.5 \times 0.382 = 8.60 \text{ kip-ft.}\\
m'\cos^2\psi_2 &= 13.2 \times 0.618 = 8.15\\
2\,m_s\sin\psi_2\cos\psi_2 &= \underline{-18.40}\\
M_2 &= -\ \ 1.65 \text{ kip-ft.}
\end{aligned}$$

$$\begin{aligned}
t_n\sin^2\psi_2 &= 6.25 \times 0.382 = 2.39 \text{ kips}\\
t'_n\cos^2\psi_2 &= 7.63 \times 0.618 = 4.71\\
2\,t_s\sin\psi_2\cos\psi_2 &= \underline{-\ \ 6.21}\\
N_2 &= 0.89 \text{ kip}
\end{aligned}$$

The foregoing computations show that M_2 and N_2 are negligible.

Normal Steel Plane 1.

$$e = \frac{37.4}{13.0} \times 12 + 8.0 = 42.2 \text{ in.}$$

$$\frac{e}{d} = \frac{42.2}{18.5} = 2.28$$

$$K = \frac{13.0 \times 2.28}{12 \times 18.5} = 134$$

$$\left.\begin{array}{l}F_{c1} = 770 \text{ lb.}\\ F_s = 19\,200 \text{ lb. (trial value)}\\ P = 0.00493\end{array}\right\}$$

Normal Steel Plane 2.

(None required)

For Plane 1, use Case IV (*A*) (Equations (64)) and for Plane 2, use Case I (*C*):

$$\sin \alpha_1 = 0.205 \quad \sin^2 \alpha_1 = 0.042$$
$$\cos \alpha_1 = 0.979 \quad \cos^2 \alpha_1 = 0.958$$
$$\sin \alpha_1 \cos \alpha_1 = 0.200$$

$$f_s\, p \cos^2 \alpha_1 = \frac{1}{2} f_{c1}\, k_1 - \frac{N_1}{b\, d} = F_s\, P = 19\,200 \times 0.00493 = 94.5$$

$$f_s\, p = \frac{94.5}{0.958} = 98.7$$

On Plane 2:

$$M_2 = 0, \therefore j_2 = 0, k_2 = 3 \left(j_2 + \frac{d'}{d}\right) = \frac{3 \times 2.50}{18.5} = 0.405$$

$$a_2 = -\left(\frac{k_2 - \frac{d'}{d}}{k_2}\right) = -\frac{2}{3}$$

$$f_s\, p \cos^2 \alpha_2 = \frac{1}{2} f_{c2}\, k_2$$

$$f_{c2} = \frac{2 \times 98.7 \times 0.042}{0.405} = 20.4 \text{ lb. per sq. in.}$$

On Plane 1:

$$\frac{d}{t} = \frac{18.5}{21.0} = 0.882$$

$$q_s = \frac{3 - \frac{6\, d}{t}}{2 - \frac{3\, d}{t}} = 3.54$$

$$a_s = -\left(1 - q_s \frac{d}{t}\right) = -(1 - 0.882 \times 3.54) = 2.12$$

$$h_1 = \frac{2\, f_s\, p\, b\, d \sin \alpha_1 \cos \alpha_1 + S}{b\, t\, (2 - q_s)}; \; S = 0 \text{ for principal planes}$$

$$h_1 = 2\, \frac{d}{t} \times \frac{f_s\, p \sin \alpha_1 \cos \alpha_1}{(2 - q_s)} = \frac{2 \times 0.882 \times 98.7 \times 0.200}{-1.58} = -22 \text{ lb.}$$

$$\frac{f_s}{n} = \Sigma\, f_c\, a \cos^2 \alpha + \lambda\, h\, a_s \sin \alpha \cos \alpha$$

$$n\, f_{c1}\left(\frac{1 - k_1}{k_1}\right) = F_s$$

$$f_s = 19\,200 \times 0.958 + 15 \times 20.4 \left(-\frac{2}{3}\right) 0.042$$
$$+ 37.5 \times (-22.0)\,(+2.12) \times 0.200$$
$$f_s = 18\,400 + (-8) + (-350) = 18\,050 \text{ lb.}$$

$$p = \frac{f_s\, p}{f_s} = \frac{98.7}{18\,000} = 0.00543$$

$$A_s = 0.00543 \times 222 = 1.20 \text{ sq. in.}$$

Maximum Horizontal Shear.—

$$\tan 2\,\psi = \frac{m - m'}{2\,m_s} = \frac{9.2}{37.9} = 0.243$$

$$\psi = 6^\circ\,50' \text{ and } \alpha_1 = (6^\circ\,50') + 50^\circ - 90^\circ = -(33^\circ\,10')$$

$$\left.\begin{array}{l}\sin\psi_1 = 0.119\\ \cos\psi_1 = 0.993\end{array}\right\} \quad \left.\begin{array}{l}\sin^2\psi_1 = 0.014\\ \cos^2\psi_1 = 0.985\end{array}\right\} \quad \left.\begin{array}{l}\sin\alpha_1 = -0.547\\ \cos\alpha_1 = 0.837\end{array}\right\}$$

$$\sin^2\psi_1 - \cos^2\psi_1 = -0.971 \qquad \sin\alpha_1\cos\alpha_1 = -0.458$$

$$\sin\psi_1\cos\psi_1 = 0.118$$

$$\begin{aligned}(m' - m)\sin\psi_1\cos\psi_1 &= (-9.2)\,(0.118) = -\ \ 1.08\\ m_s\,(\sin^2\psi_1 - \cos^2\psi_1) &= 19.0 \times (-0.971) = \underline{-18.48}\end{aligned}$$

$$M_s = -19.56 \text{ kip-ft.}$$

$$\begin{aligned}(t'_n - t_n)\sin\psi_1\cos\psi_1 &= (-1.38)\,(0.118) = -\ \ 0.16\\ t_s\,(\sin^2\psi_1 - \cos^2\psi_1) &= 6.40 \times (-0.971) = \underline{-\ \ 6.22}\end{aligned}$$

$$S = -\ \ 6.38 \text{ kips}$$

$$f_s\,p\sin\alpha_1\cos\alpha_1 = \frac{1}{2}\,h\,(2 - q_s)\,\frac{t}{d} - \frac{S}{b\,d}$$

$$f_s\,p\sin\alpha_1\cos\alpha_1 = 98.7 \times (-0.458) = -45.2$$

$$\frac{S}{b\,d} = \frac{-6380}{12 \times 18.5} = \frac{-29.7}{-74.9}$$

$$\frac{1}{2}\,h\,(2 - q_s) = \frac{d}{t} \times (-74.9) = -66.0$$

$$e_s = \frac{-19.56}{-6.38} \times 12 + 8.0 = 44.9 \text{ in.}$$

$$K_s = \frac{S\,e_s}{b\,t^2} = \frac{(-6.38) \times 44.9}{12 \times 21 \times 21} = -54.2$$

$$\left.\begin{array}{l}\dfrac{K_s}{j_s} = \dfrac{1}{2}\,h\,(2 - q_s) = -\dfrac{54.2}{j_s}\\[2ex] \phantom{\dfrac{K_s}{j_s} =}\ \dfrac{1}{2}\,h\,(2 - q_s) = -66.0\end{array}\right\} \begin{array}{l}\dfrac{54.2}{j_s} = 66.0\\[2ex] j_s = 0.820\end{array}$$

$$q_s = \frac{3 + 6\,j_s - 6\,\dfrac{d}{t}}{2 + 3\,j_s - 3\,\dfrac{d}{t}} = \frac{3 + 6\,(0.820 - 0.882)}{2 + 3\,(0.820 - 0.882)} = 1.438$$

$$h = \frac{2 \times (-66.0)}{2 - q_s} = \frac{-132.0}{0.562} = -235 \text{ lb. ((O.K.), 240 lb. allowed)}$$

$$h' = (1 - q_s)\,h = (1 - 1.438)\,(-235) = 103 \text{ lb. (O.K.)}$$

Maximum Radial Shear.—

$$V = \frac{t_u}{b} - \frac{8}{5}\,\frac{m_v - \varepsilon'\,m_z}{b\,t}$$

$$V = \frac{38}{66.9} - \frac{8}{5}\,\frac{(-9.2)}{21 \times 66.9} = 0.58 \text{ kip.}$$

$$V_{\text{max.}} = 0.580 \times 2.42 = 1.4 \text{ kips}\,;\ v = \frac{1400}{0.8 \times 12 \times 18.5} = 7.9 \text{ lb. (O.K.)}$$

Design of Steel at the Section, $x = 20.6$

$$t = 54 \text{ in.}$$

$$\varepsilon' = \varepsilon = 1.192 \qquad \varepsilon'^2 = 1.420$$

$$\left.\begin{aligned} m_z &= -\,5\,930 \text{ kip-ft.} \\ t_v &= 803 \text{ kips} \end{aligned}\right\} \quad \left.\begin{aligned} m_v &= -\,6\,740 \text{ kip-ft.} \\ t_z &= 667 \text{ kips} \end{aligned}\right\}$$

Center Stresses.—

$$\begin{array}{lll} m = -\,88.6 \text{ kip-ft.} & & t_n = 12.0 \text{ kips} \\ m' = -\,120.0 \quad `` & & t_n = 6.56 \quad `` \\ m_s = -\,103.3 \quad `` & & t_s = 5.5 \quad `` \end{array}\left.\vphantom{\begin{array}{l}a\\a\\a\end{array}}\right\}$$

Fascia Steel.—

$$M = -\,88.6 \sec^2 \theta'$$

$$N = 12.0 \sec^2 \theta'$$

$$e' = \frac{-\,88.6}{12.0} \times 12 - 24.5 = -\,113.1 \text{ in.}$$

$$\frac{e'}{d} = -\frac{113.1}{51.5} = -\,2.20$$

$$K = \frac{12.0 \times (-\,2.20) \times 2.42}{12 \times 51.5} = -\,103.5$$

$$f_c = 650$$

$$f'_s = 18\,000$$

$$p' = 0.0039$$

$$A'_s = 0.0039 \times 51.5 \times 12 = 2.41 \text{ sq. in.}$$

Center Steel.—

(*a*) Minimum Cross-Steel.—

$$\psi = 180 - \theta'$$

$$\begin{aligned} m \sin^2 \theta' &= -\,88.6 \times 0.587 = -\;\;52.0 \\ m' \cos^2 \theta' &= -\,120.0 \times 0.413 = -\;\;49.5 \\ -\,2\, m_s \sin \theta' \cos \theta' &= 206.6 \times 0.492 = \;\;101.5 \\ & \qquad\qquad\qquad\qquad\quad \overline{\qquad 0 \qquad} \end{aligned}$$

$$\begin{aligned} t_n \cos^2 \theta' &= 12.0 \times 0.587 = \;\;7.05 \\ t'_n \sin^2 \theta' &= 6.56 \times 0.413 = \;\;2.71 \\ -\,2\, t_s \sin \theta' \cos \theta' &= 11.0 \times 0.492 = -\;\;5.41 \\ N &= \;\;4.35 \text{ kips} \end{aligned}$$

The foregoing computations show that no steel is required.

(*b*) Minimum Longitudinal Steel.—

$$\begin{aligned} m \cos^2 \theta' &= -\,88.6 \times 0.413 = -\;\;36.6 \\ m' \sin^2 \theta' &= -\,120.0 \times 0.587 = -\;\;70.4 \\ 2\, m_s \sin \theta' \cos \theta' &= -\,101.5 \\ M &= -\,208.5 \text{ kip-ft.} \end{aligned}$$

$$\begin{aligned} t_n \cos^2 \theta' &= 12.0 \times 0.413 = \;\;4.96 \\ t'_n \sin^2 \theta' &= 6.56 \times 0.587 = \;\;3.84 \\ 2\, t_s \sin \theta' \cos \theta' &= \;\;5.41 \\ N &= 14.21 \text{ kips} \end{aligned}$$

$$f_c = 600$$
$$f'_s = 18\,000$$
$$p' = 0.43\%$$
$$A'_s = 2.65 \text{ sq. in.}$$

(*c*) Principal Planes (Case V).—

$$\tan 2\,\psi = \frac{2\,m_s}{m' - m} = \frac{-\,206.6}{-\,31.4} = 6.57$$

$$\psi_1 = 40^\circ\,40'$$

$$M_1 = -\,208.9 \qquad N_1 = 14.30$$
$$M_2 = 0 \qquad N_2 = 4.24 \text{ (negligible)}$$

$$\alpha_1 = \psi_1 + \theta - 90 = 0^\circ\,40' \text{ (which is negligible)}$$

The design is for normal steel which gives the same condition as for minimum longitudinal steel.

Maximum Horizontal Shear.—

$$\tan 2\,\psi = \frac{m - m'}{2\,m_s} = 0.152$$

$$\psi_1 = 4^\circ\,20' \qquad \alpha_1 = (4^\circ\,20') + 50^\circ - 90^\circ = -\,(35^\circ\,40')$$

$$\left.\begin{array}{l} M_s = 103.3 \text{ kip-ft.} \\ S = -\,5.5 \text{ kips} \end{array}\right\} \qquad \frac{d}{t} = 0.973 \qquad \frac{d'}{t} = 0.027$$

$$e'_s = \frac{103.3}{-\,5.5} \times 12 - 24 = -\,250$$

$$f'_s\,p' \sin \alpha_1 \cos \alpha_1 = \frac{1}{2}\,h\,(2 - q_s)\,\frac{t}{d} - \frac{S}{b\,d}$$

$$f'_s\,p' \sin \alpha_1 \cos \alpha_1 = 18\,000 \times 0.0043 \times (-\,0.473) = -\,36.6 \text{ lb.}$$

$$\frac{S}{b\,d} = -\,\frac{5\,500}{54.5 \times 12} = \begin{array}{r} -\ 8.4\ \text{“} \\ \hline -\ 45.0 \text{ lb.} \end{array}$$

$$\frac{1}{2}\,h\,(2 - q_s) = -\,45.0 \times 0.973 = -\,43.8$$

$$K_s = \frac{S\,e'_s}{b\,t^2} = \frac{(-\,5.50)\,(-\,250)}{12 \times 54.0 \times 54.0} = +\,39.2$$

$$\frac{1}{2}\,h\,(2 - q_s) = -\,\frac{K_s}{j'_s} = \frac{-\,39.2}{j'_s} = -\,43.8$$

$$j'_s = \frac{-\,39.2}{-\,43.8} = +\,0.900$$

$$q_s = \frac{3 - 6\,j'_s - 6\,\dfrac{d'}{t}}{2 - 3\,j'_s - 3\,\dfrac{d'}{t}} = \frac{-\,2.562}{-\,0.781} = 3.28$$

$$h = \frac{-\,43.8 \times 2}{-\,1.28} = 68.5 \text{ lb.}$$

$$h' = (1 - q_s)\,h = -\,2.28 \times 68.5 \text{ lb.} = -\,156 \text{ lb. (O. K.)}$$

Section at Top of Post (Omitted from Table 8).

$$\left.\begin{array}{l} m_z = -6\,365 \text{ kip-ft.} \\ t_v = 1\,181 \text{ kips} \end{array}\right\} \quad \left.\begin{array}{l} m_v = -1\,554 \text{ kip-ft.} \\ t_z = 630 \text{ kips} \end{array}\right\} \quad \begin{array}{ll} t = 36 \text{ in.} & \varepsilon' = \varepsilon \cos 90^\circ = 0 \\ d = 33.5 \text{ in.} & \sec^2 \theta' = 1 \end{array}$$

$$\left.\begin{array}{ll} m = -95.0 \text{ kip-ft.} & t_n = 17.8 \text{ kips} \\ m' = 0 & t'_n = 0 \\ m_s = -10.6 \text{ kip-ft.} & t_s = 14.1 \text{ kips} \end{array}\right\} \text{at center}$$

Fascia Steel.—

$$\left.\begin{array}{l} M = m \\ N = t_n \end{array}\right\} \quad \begin{array}{l} f_c = 660 \text{ lb.} \\ f'_s = 18\,000 \text{ lb.} \\ p' = 0.0042 \\ A_s = 0.0042 \times 12 \times 33.5 = 1.69 \text{ sq. in.} \end{array}$$

Center Steel.—

(*a*) Minimum Cross Steel.—

$$\psi = 180 - \theta' = 180^\circ$$

$$M = 0, \ N = 0 \text{ (no steel required).}$$

(*b*) Minimum Longitudinal Steel.—

$$M = m, N = t_n \text{ (same as fascia steel).}$$

(*c*) Principal Planes.—

$$\tan 2\,\psi = \frac{2\,m_s}{m' - m} = \frac{-21.2}{95.0} = -0.224$$

$$\tan (180 - 2\,\psi) = 0.224$$

$$\psi = 83^\circ\,30'$$

$$\left.\begin{array}{l} M_1 = -96.7 \text{ kip-ft.} \\ N_1 = 21.0 \text{ kips} \end{array}\right\} \left.\begin{array}{l} M_2 = 1.22 \text{ kip-ft.} \\ N_2 = 3.07 \text{ kips} \end{array}\right\} \alpha_1 = (83^\circ\,30') - 90^\circ = -(6^\circ\,30')$$

This computation shows that the same steel as the fascia steel should be used.

Maximum Horizontal Shear.—Shear is "O. K." by inspection.

Example of Design for Steel in Two Directions

$$\text{Assume} \left\{\begin{array}{l} M_1 = 18.0 \text{ kip-ft.} \quad N_1 = 12.32 \text{ kips} \quad \alpha_1 = 20^\circ\,25' \\ M_2 = 36.5 \text{ kip-ft.} \quad N_2 = 2.68 \text{ kips} \quad \alpha_2 = 110^\circ\,25' \\ t = 21.0 \text{ in.}, d = 18.5 \text{ in.} \\ \text{Minimum steel..0.18\% longitudinal} \\ \text{Minimum steel..0.63\% cross} \end{array}\right.$$

Normal Steel, Plane 1.	Normal Steel, Plane 2.
$K = 77, \dfrac{e}{d} = 1.38$	$K = 112, \dfrac{e}{d} = 9.28$
$F_{s1} = 19\,000$ lb. (trial value)	$F_{s2} = 16\,500$ lb. (trial value)
$F_{c2} = 575$ lb.	$F_{c2} = 710$ lb.
$P_1 = 0.18\%$	$P_2 = 0.70\%$

For the following computations use Equations (64), Case X (*A*).

$$\sum f_s\, p\, b\, d \cos^2 \alpha = \frac{1}{2} f_c\, k\, b\, d - N = F_s\, P\, b\, d$$

$$\left.\begin{aligned} 0.879 f_\alpha\, p_\alpha + 0.121 f_\beta\, p_\beta &= 19\,500 \times 0.0017 = 33.2 \\ 0.121 f_\alpha\, p_\alpha + 0.879 f_\beta\, p_\beta &= 16\,500 \times 0.007 \;\; = 115 \end{aligned}\right\}$$

Solving,

$$\left\{\begin{aligned} f_\alpha\, p_\alpha &= 20 \\ f_\beta\, p_\beta &= 129 \end{aligned}\right.$$

from which, $q_s = 3.58$; $h = 40$ lb.; and $a_s = -2.16$

$$\lambda\, n\, h\, a_s \sin \alpha_1 \cos \alpha_1 = -1\,050 \text{ lb.}$$

$$f_s = \sum f_c\, a \cos^2 \alpha + \lambda\, h\, a_s \sin a_1 \cos \alpha.$$

$$f_\alpha = 19\,500 \times 0.879 + 16\,500 \times 0.121 - 1\,050 = 18\,100 \text{ lb.}$$

$$f_\beta = 19\,500 \times 0.121 + 16\,500 \times 0.879 + 1\,050 = 17\,850 \text{ lb.}$$

$$p_\alpha = \frac{20}{18\,000} = 0.11\%$$

$$p_\beta = \frac{129}{18\,000} = 0.64\%$$

SUMMARY

In Part II, the theory for proportioning sections has been developed. Equations have been derived for (*a*) stress distribution; (*b*) transformation formulas; and (*c*) design formulas for skew reinforced concrete sections. The application of these formulas is illustrated by the preceding numerical examples. This part of the paper, together with Part I, gives the designer a complete working text for designing skew arches.

PART III.—APPROXIMATE ANALYSIS FOR CROWN STRESSES IN A SYMMETRICAL SKEW RIGID FRAME

The rigid frame is a special type of arch and is analyzed as an arch, but the shape of the frame is such that the angle, ϕ (as previously defined), is either nearly 0°, or nearly 90 degrees. From the analyses of two skew rigid frames, the writer found that a considerable variation in the value of the angle, ϕ, produced negligible changes in the crown stresses. These observations lead to the following approximations:

1.—(*a*) $\phi = 0°$ for the barrel of the frame.
(*b*) $\phi = 90°$ for the post of the frame.

2.—The effect of the curvature of the barrel of the frame can be neglected in places where other characteristics of the frame affect the magnitude of the stress.

These approximations have the effect of transforming the actual frame shown in Fig. 24 into the frame shown in Fig. 25. It should be noted that M_y is a direct result of the curvature of the neutral axis (that is, M_y would be zero if the neutral axis were truly straight), and the accurate analysis must be used to compute it. Fortunately, this is a simple matter. Furthermore, $M_y = 0$ for symmetrical loads and temperature variation. Making these approximations results in the following.

APPROXIMATE FINAL EQUATIONS FOR SYMMETRICAL TWO-HINGED RIGID FRAMES

Let T'_x equal the crown thrust of a right rigid frame produced by two parallel planes cutting the skew arch perpendicular to the abutments. All other symbols are as previously defined.

For Vertical Loading.—

$$\left.\begin{aligned}
T_x &= T'_x \\
T_z &= \varepsilon\, T_x \\
M_x &= \frac{\varepsilon\left[\sum_B^P x\,\dfrac{s}{I} - x'\sum_B^P \dfrac{s}{I}\right]}{2\sum_B^C \dfrac{s}{I}} \\
M_z\,,\ T_y &= \text{same as for right arch} \\
M_y &= \frac{C_6 - K_3\,T_y}{K_{10}}, \text{as given in accurate theory}
\end{aligned}\right\}\ldots\ldots\ldots(65A)$$

For Horizontal Loading.—

$$\left.\begin{aligned}
T_x &= T'_x \\
T_z &= \varepsilon\, T_x \\
M_x &= 0 \\
T_y,\ M_z &= \text{same as for right arch} \\
M_y &= \frac{C_6 - K_3\,T_y}{K_{10}}, \text{as given in accurate theory}
\end{aligned}\right\}\ldots\ldots\ldots(65B)$$

For Temperature Stresses.—

$$\left.\begin{aligned}
T_x &= T'_x \sec^2\theta \\
T_z &= \varepsilon\left(T_x + \frac{1.34\,E\,c\,t\,L}{\sum_A^B x^2\,\dfrac{s}{I}}\right) \\
M_x &= 0 \\
M_y &= 0 \\
M_z &= -\,h\,T_x \\
T_y &= 0
\end{aligned}\right\}\ldots\ldots\ldots\ldots\ldots\ldots(65C)$$

The origin for x in these equations is at the center.

DERIVATION OF APPROXIMATE COEFFICIENTS
(SEE EQUATIONS (19) AND FIG. 25)

For All Loading.—

From A to B ($\phi = 90$; $u = x$):

$$\left.\begin{aligned}
K_{11} &= \sum_A^B y^2\,\frac{s}{I} - 2\,h\sum_A^B y\,\frac{s}{I} + h^2\sum_A^B \frac{s}{I} + \varepsilon^2\sum_A^B x^2\,\frac{\lambda\,s}{F} \\
K_2 &= \varepsilon\sum_A^B x^2\,\frac{\lambda\,s}{F};\ K_3 = 0;\ K_5 = \sum_A^B x^2\,\frac{\lambda\,s}{F};\ K_6 = 0 \\
K_7 &= 0
\end{aligned}\right\}\ldots(66A)$$

From B to C $(\phi = 0;\ u = y = 0)$:

$$\left.\begin{aligned} K_{11} &= h^2 \sum\nolimits_B^C \frac{s}{I} \\ K_2 &= 0;\ K_3 = 0;\ K_5 = 0;\ K_6 = 0 \\ K_7 &= \sum\nolimits_B^C \frac{\lambda\, s}{F} \end{aligned}\right\} \ldots\ldots\ldots\ldots\ldots\ldots (66B)$$

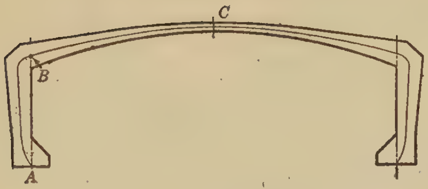

FIG. 24.—TYPICAL "RIGID FRAME."

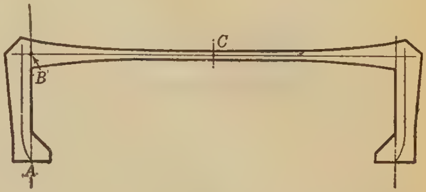

FIG. 25.—TRANSFORMED "RIGID FRAME."

For Vertical Loading.—

From A to B $(\phi = 90;\ u = x)$:

$$\left.\begin{aligned} C_{11} &= \frac{1}{2}\Big[(L - x')\Big(-\sum\nolimits_A^B y\,\frac{s}{I} + h \sum\nolimits_A^B \frac{s}{I}\Big) + \sum\nolimits_A^B x\,y\,\frac{s}{I} \\ &\qquad - x' \sum\nolimits_A^B y\,\frac{s}{I} - h \sum\nolimits_A^B x\,\frac{s}{I} + h\,x' \sum\nolimits_A^B \frac{s}{I}\Big] \\ C_2 &= C_3 = C_6 = 0 \end{aligned}\right\} \ldots (67A)$$

From B to C $(\phi = 0;\ u = y = 0)$:

$$\left.\begin{aligned} C_{11} &= \frac{1}{2}\Big[(L - x')\Big(h \sum\nolimits_B^C \frac{s}{I}\Big) - h \sum\nolimits_B^P x\,\frac{s}{I} + h\,x' \sum\nolimits_B^P \frac{s}{I}\Big] \\ C_2 &= 0 \\ C_3 &= \frac{1}{2}\Big[\varepsilon \sum\nolimits_B^P x\,\frac{\lambda\, s}{F} - \varepsilon\,x' \sum\nolimits_B^P \frac{\lambda\, s}{F}\Big] \\ C_6 &= 0 \end{aligned}\right\} . (67B)$$

For Horizontal Loading.—

From A to B $(\phi = 90;\ u = x)$:

$$\left.\begin{aligned} C_{11} &= \frac{1}{2}\Big[(h - y')\Big(-\sum\nolimits_A^B y\,\frac{s}{I} + h \sum\nolimits_A^B \frac{s}{I}\Big) + \sum\nolimits_A^P y^2\,\frac{s}{I} \\ &\qquad - y' \sum\nolimits_A^P y\,\frac{s}{I} - h \sum\nolimits_A^P y\,\frac{s}{I} + h\,y' \sum\nolimits_A^P \frac{s}{I}\Big] \\ C_2 &= 0;\ C_3 = 0;\ C_6 = 0 \end{aligned}\right\} \ldots (68A)$$

From B to C $(\phi = 0;\ u = y = 0)$:

$$\left.\begin{aligned} C_{11} &= \frac{1}{2}\Big[(h - y')\Big(h \sum\nolimits_B^C \frac{s}{I}\Big)\Big] \\ C_2 &= 0;\ C_3 = 0;\ C_6 = 0 \end{aligned}\right\} \ldots\ldots\ldots\ldots (68B)$$

For Temperature Stresses.—

$$C_{11} = E\,c\,t\,L;\ C_2 = \varepsilon\,E\,c\,t\,L;\ C_3 = C_4 = C_5 = C_6 = 0 \ldots\ldots (69)$$

APPROXIMATE COEFFICIENTS

Combining the two parts of Equations (66), (67), and (68), the approximate coefficients become:

For All Loading.—

$$K_{11} = \sum_A^B y^2 \frac{s}{I} - 2\,h \sum_A^B y \frac{s}{I} + h^2 \sum_A^C \frac{s}{I} + \varepsilon^2 \sum_A^B x^2 \frac{s}{I}$$

$$K_2 = -\,\varepsilon] \sum_A^B x^2 \frac{\lambda\, s}{F};\ K_3 = 0;\ K_5 = \sum_A^B x^2 \frac{\lambda\, s}{F};\ K_6 = 0;\ K_7 = \sum_B^C \frac{\lambda\, s}{F}$$

For Vertical Loading.—

$$C_{11} = \frac{1}{2}\Bigg[(L - x')\left(-\sum_A^B y \frac{s}{I} + h \sum_A^C \frac{s}{I}\right) + \sum_A^B x\, y \frac{s}{I}$$
$$- x' \sum_A^B y \frac{s}{I} - h \sum_A^P x \frac{s}{I} + h\, x' \sum_A^P \frac{s}{I}\Bigg]$$

$$C_2 = 0$$

$$C_3 = \frac{1}{2}\,\varepsilon\left[\sum_B^P x \frac{\lambda\, s}{F} - x' \sum_B^P \frac{\lambda\, s}{F}\right]$$

For Horizontal Loading.—

$$C_{11} = \frac{1}{2}\Bigg[(h - y')\left(-\sum_A^B y \frac{s}{I} + h \sum_A^C \frac{s}{I}\right) + \sum_A^P y^2 \frac{s}{I}$$
$$- y' \sum_A^P y \frac{s}{I} - h \sum_A^P y \frac{s}{I} + h\, y' \sum_A^P \frac{s}{I}\Bigg]$$

$$C_2 = 0;\ C_3 = 0$$

For Temperature.—

$$C_1 = E\, c\, t\, L$$
$$C_2 = \varepsilon\, E\, c\, t\, L$$
$$C_3 = 0$$

DERIVATION OF FINAL EQUATIONS

For Vertical Loading.—Substituting the foregoing coefficients in Equation (19*b*) (Appendix I):

$$T_z = \frac{K_2\, T_x}{K_5} = \frac{\varepsilon \sum_A^B x^2 \frac{\lambda\, s}{F}}{\sum_A^B x^2 \frac{\lambda\, s}{F}}\, T_x$$

therefore,

$$T_z = \varepsilon\, T_x$$

Substituting this value of T_z and the foregoing coefficients in Equation (19*a*) (Appendix I):

$$T_x = \frac{C_{11}}{K_{11} + \varepsilon\, K_2} = \frac{C_{11}}{K'_{11}}$$

in which,

$$K'_{11} = \sum_A^B y^2 \frac{s}{I} - 2\,h \sum_A^B y \frac{s}{I} + h^2 \sum_A^C \frac{s}{I}$$

therefore,

$$T_x = T'_x$$

Similarly, from Equation (19*c*) (Appendix I):

$$M_x = \frac{K_3}{K_7} = \frac{1}{2} \frac{\varepsilon \left[\sum_B^P x \frac{\lambda s}{F} - x' \sum_B^P \frac{\lambda s}{F} \right]}{\sum_B^C \frac{\lambda s}{F}}$$

but,

$$\frac{\lambda}{F} = \frac{3.58 \lambda}{b t^3} = \frac{3.58 \lambda}{12 I}$$

Substituting this value of $\frac{\lambda}{F}$ and cancelling out the constants:

$$M_x = \frac{\varepsilon \left[\sum_B^P x \frac{s}{I} - x' \sum_B^P \frac{s}{I} \right]}{2 \sum_B^C \frac{s}{I}}$$

For Horizontal Loading.—Similarly:

$$T_x = T'_x;\ T_z = \varepsilon T_x;\ \text{and } M_x = 0$$

For Temperature Stresses.—Substituting the approximate coefficients in Equations (19*a*) and (19*b*):

$$\left. \begin{aligned} K_{11} T_x + K_2 T_z &= C_{11} \\ K_2 T_x + K_5 T_z &= C_2 = \varepsilon C_{11} \end{aligned} \right\} \quad \text{..................(70)}$$

Solving:

$$T_x = \frac{C_{11} K_5 - \varepsilon C_{11} K_2}{K_{11} K_5 - K_2^2}$$

but,

$$K_5 = -\frac{K_2}{\varepsilon}$$

Therefore,

$$T_x = \frac{C_{11} (1 + \varepsilon^2)}{K_{11} + \varepsilon K_2} = \frac{C_{11}}{K'_{11}} \sec^2 \theta$$

or,

$$T_x = T'_x \sec^2 \theta$$

From the second of Equations (70):

$$T_z = \frac{\varepsilon C_{11} - K_2 T_x}{K_5} = \frac{\varepsilon E c t L}{\sum_A^B x^2 \frac{\lambda s}{F}} + \varepsilon T_x$$

but,

$$\frac{\lambda}{F} = \frac{3.58 \times 2.5}{12 I} = \frac{1}{1.34 I}$$

Therefore,

$$T_z = \varepsilon \left[T_x + \frac{1.34 E c t L}{\sum_A^B x^2 \frac{s}{I}} \right]$$

Similarly, from Equation (19*c*), $M_x = 0$.

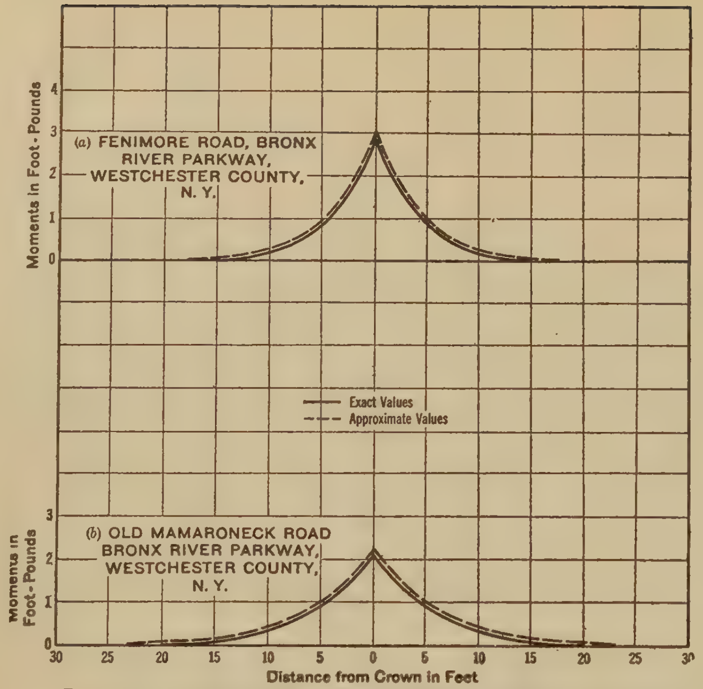

FIG. 26.—COMPARATIVE INFLUENCE LINES FOR TORSION MOMENT BY EXACT AND APPROXIMATE EQUATIONS.

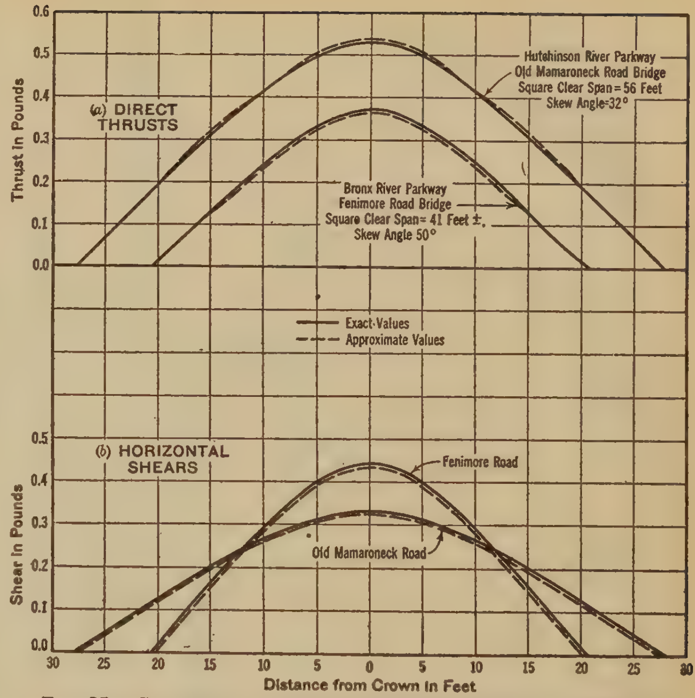

FIG. 27.—COMPARATIVE INFLUENCE LINES FOR DIRECT THRUST AND HORIZONTAL SHEAR BY EXACT AND APPROXIMATE EQUATIONS.

The relations just derived are true for the frame shown in Fig. 25. It is assumed that the same relations hold true for the frame in Fig. 24. The closeness of the approximation is shown by the influence lines of Fig. 26 and Fig. 27.

EXAMPLE 3.—APPLICATION OF APPROXIMATE THEORY

In a right symmetrical arch, it is somewhat more convenient to take the origin at the center of the span at the elevation of the hinges. When using Equations (2) and (3) of the more exact theory, $h—y$ must be written for y.

The right arch equations used herein can be derived from the skew arch equations by making $\epsilon = 0$ and writing $h—y$ for y, or they can be derived as follows.

For Vertical Loading.—From Fig. 28:

$$T'_x = \frac{\sum_A^B M y \frac{s}{I}}{\sum_A^B y^2 \frac{s}{I}} = \left[\frac{\sum_A^C \left(\frac{L - x'}{2L}\right)(L + x)\, y \frac{s}{I}}{\sum_A^C y^2 \frac{s}{I} + \sum_C^B y^2 \frac{s}{I}} \right.$$

$$\left. + \frac{\sum_C^B \left(\frac{L - x'}{2L}\right)(L - x)\, y \frac{s}{I}}{\sum_A^C y^2 \frac{s}{I} + \sum_C^B y^2 \frac{s}{I}} - \frac{\sum_A^B (x - x')\, y \frac{s}{I}}{\sum_A^C y^2 \frac{s}{I} + \sum_C^B y^2 \frac{s}{I}} \right] P$$

FIG. 29.

ACKNOWLEDGMENTS

The writer wishes to express his gratitude to Mr. Hayden for the encouragement he has received in the preparation of this paper. He is also under obligation to two other members of the Design Division of the Westchester County Park Commission, Mr. Aaron Cohen, who checked Part I, and William R. Frederick, Jr., Jun. Am. Soc. C. E., who checked Parts II and III of the paper.

APPENDIX I

In this section of the paper all final equations necessary for the design of skew arches are grouped together. It will be noted that the equation numbers are discontinuous. The purpose has been to arrange the formulas in such a way that any one using them may turn back to the text for an explanation or derivation. For example, Equations (16) follow Equations (3) in Appendix I. Both these sets are essential in a design, whereas Equations (1), (2), and (4) to (15), inclusive, etc., in the main paper, are necessary only for the derivation of the final design equations. The number of the equations in Appendix I serve to identify their normal position in the paper, where the derivations are given.

EQUATIONS FOR COMPUTING TOTAL STRESSES

Equations (2), (3), (16), (19), (20), (21), (25), and (27), which follow, are explained in Part I.

Symmetrical Arches

For formulas to apply to the design of symmetrical arches use Equations (2), (3), (16), and (19), as follows:

Stresses at a Section.—

$$t_v = T_x \cos \phi \mp T_y \sin \phi + W \sin \phi - H \cos \phi \tag{2a}$$

$$t_u = \pm T_x \sin \phi + T_y \cos \phi \mp W \cos \phi \mp H \sin \phi \tag{2b}$$

$$t_z = T_z \tag{2c}$$

$$\begin{aligned} m_v = {} & T_x \, \varepsilon \, x \sin \phi \pm T_y \, \varepsilon \, x \cos \phi - T_z \, u + M_x \cos \phi \mp M_y \sin \phi \\ & - W \, \varepsilon \, (x - x') \cos \phi - H \, \varepsilon \, (x - x') \sin \phi \end{aligned} \tag{2d}$$

$$\begin{aligned} m_u = {} & \mp T_x \, \varepsilon \, x \cos \phi + T_y \, \varepsilon \, x \sin \phi \pm T_z \, v \pm M_x \sin \phi + M_y \cos \phi \\ & \mp W \, \varepsilon \, (x - x') \sin \phi \pm H \, \varepsilon \, (x - x') \cos \phi \end{aligned} \tag{2e}$$

$$m_z = T_x \, y \pm T_y \, x + M_z - W \, (x - x') - H \, (y - y') \tag{2f}$$

The upper signs in Equations (2) apply to the left half of the structure, and the lower signs apply to the right half. The loads, W and H, apply to either half of the arch.

Co-Ordinates of Crown Section with Respect to Any Point, P.—

$$u = x \sin \phi - y \cos \phi \tag{3a}$$

$$v = x \cos \phi + y \sin \phi \tag{3b}$$

Final Equations for the Fixed Symmetrical Arch (Origin of Co-Ordinates Is at Crown Center).—

$$K_4 \, T_x + K_8 \, M_z = C_4 \tag{16a}$$

$$K_1 \, T_x + K_2 \, T_z + K_3 \, M_x + K_4 \, M_z = C_1 \tag{16b}$$

$$K_2 \, T_x + K_5 \, T_z + K_6 \, M_x = C_2 \tag{16c}$$

$$K_3 \, T_x + K_6 \, T_z + K_7 \, M_x = C_3 \tag{16d}$$

$$K_9 \, T_y + K_3 \, M_y = C_5 \tag{16e}$$

and,

$$K_3 \, T_y + K_{10} \, M_y = C_6 \tag{16f}$$

in which, the coefficients are, for all loading and temperature stresses:

$$K_1 = \sum y^2 \frac{s}{I} + \varepsilon^2 \sum x^2 \sin^2 \phi \, \lambda \frac{s}{F}$$

$$K_2 = - \varepsilon \sum u \, x \sin \phi \, \lambda \frac{s}{F}$$

$$K_3 = + \varepsilon \sum x \sin \phi \cos \phi \, \lambda \frac{s}{F}$$

$$K_4 = + \sum y \frac{s}{I}$$

$$K_5 = + \sum u^2 \lambda \frac{s}{F}$$

$$K_6 = - \sum u \cos \phi \, \lambda \frac{s}{F}$$

$$K_7 = + \sum \cos^2 \phi \, \lambda \frac{s}{F}$$

$$K_8 = + \sum \frac{s}{I}$$

$$K_9 = - \sum x^2 \frac{s}{I} - \varepsilon^2 \sum x^2 \cos^2 \phi \, \lambda \frac{s}{F}$$

and,

$$K_{10} = - \sum \sin^2 \phi \, \lambda \frac{s}{F}$$

For a vertical load, W, at the point, $x = x'$, $z = \varepsilon x'$:

$$\begin{aligned} C_1 = \frac{1}{2} \Big[& \sum_A^P x \, y \frac{s}{I} - x' \sum_A^P y \frac{s}{I} + \varepsilon^2 \sum_A^P x^2 \sin \phi \cos \phi \, \lambda \frac{s}{F} \\ & - \varepsilon^2 x' \sum_A^P x \sin \phi \cos \phi \, \lambda \frac{s}{F} \Big] W \end{aligned}$$

$$C_2 = \frac{1}{2} \left[- \varepsilon \sum_A^P u \, x \cos \phi \, \lambda \frac{s}{F} + \varepsilon x' \sum_A^P u \cos \phi \, \lambda \frac{s}{F} \right] W$$

$$C_3 = \frac{1}{2} \left[\varepsilon \sum_A^P x \cos^2 \phi \, \lambda \frac{s}{F} - \varepsilon x' \sum_A^P \cos^2 \phi \, \lambda \frac{s}{F} \right] W$$

$$C_4 = \frac{1}{2} \left[\sum_A^P x \frac{s}{I} - x' \sum_A^P \frac{s}{I} \right] W$$

$$\begin{aligned} C_5 = \frac{1}{2} \Big[& - \sum_A^P x^2 \frac{s}{I} + x' \sum_A^P x \frac{s}{I} - \varepsilon^2 \sum_A^P x^2 \cos^2 \phi \, \lambda \frac{s}{F} \\ & + \varepsilon^2 x' \sum_A^P x \cos^2 \phi \, \lambda \frac{s}{F} \Big] W \end{aligned}$$

and,

$$C_6 = \frac{1}{2} \left[\varepsilon \sum_A^P x \sin \phi \cos \phi \, \lambda \frac{s}{F} - \varepsilon x' \sum_A^P \sin \phi \cos \phi \, \lambda \frac{s}{F} \right] W$$

For a horizontal load, H, at the point, $y = y'$, $z = \varepsilon x'$:

$$\begin{aligned} C_1 = \frac{1}{2} \Big[& \sum_A^P y^2 \frac{s}{I} - y' \sum_A^P y \frac{s}{I} + \varepsilon^2 \sum_A^P x^2 \sin^2 \phi \, \lambda \frac{s}{F} \\ & - \varepsilon^2 x' \sum_A^P x \sin^2 \phi \, \lambda \frac{s}{F} \Big] H \end{aligned}$$

$$C_2 = \frac{1}{2}\left[-\varepsilon \sum_A^P u\, x \sin\phi\, \lambda \frac{s}{F} + \varepsilon\, x' \sum_A^P u \sin\phi\, \lambda \frac{s}{F}\right] H$$

$$C_3 = \frac{1}{2}\left[\varepsilon \sum_A^P x \sin\phi \cos\phi\, \lambda \frac{s}{F} - \varepsilon\, x' \sum_A^P \sin\phi \cos\phi\, \lambda \frac{s}{F}\right] H$$

$$C_4 = \frac{1}{2}\left[\sum_A^P y \frac{s}{I} - y' \sum_A^P \frac{s}{I}\right] H$$

$$C_5 = \frac{1}{2}\left[-\sum_A^P x\, y \frac{s}{I} + y' \sum_A^P x \frac{s}{I} - \varepsilon^2 \sum_A^P x^2 \sin\phi \cos\phi\, \lambda \frac{s}{F} + \varepsilon^2 x' \sum_A^P x \sin\phi \cos\phi\, \lambda \frac{s}{F}\right] H$$

and,

$$C_6 = \frac{1}{2}\left[\varepsilon \sum_A^P x \sin^2\phi\, \lambda \frac{s}{F} - \varepsilon\, x' \sum_A^P \sin^2\phi\, \lambda \frac{s}{F}\right] H$$

For temperature stresses ($t°$ rise):

$$C_1 = E\, c\, t\, L; \quad C_2 = \varepsilon\, E\, c\, t\, L; \text{ and, } C_3 = C_4 = C_5 = C_6 = 0$$

All the summations are from A to C (Fig. 29) unless otherwise noted.

Final Equations for the Two-Hinged Symmetrical Arch (Origin of Co-Ordinates at Crown Center).—As in the case of the fixed arch, the final equations are written in terms of the coefficients, K and C:

$$K_{11}\, T_x + K_2\, T_z + K_3\, M_x = C_{11} \quad \text{(19a)}$$

$$K_2\, T_x + K_5\, T_z + K_6\, M_x = C_2 \quad \text{(19b)}$$

$$K_3\, T_x + K_6\, T_z + K_7\, M_x = C_3 \quad \text{(19c)}$$

$$M_z = C_{14} - h\, T_x \quad \text{(19d)}$$

$$T_y = C_{15} \quad \text{(19e)}$$

$$K_{10}\, M_y = C_6 - K_3\, T_y \quad \text{(19f)}$$

All the coefficients given in Equations (19) have the same values as those in Equations (16), with the following additional values:

For all loading and temperature stresses:

$$K_{11} = \sum y^2 \frac{s}{I} - 2\, h \sum y \frac{s}{I} + h^2 \sum \frac{s}{I} + \varepsilon^2 \sum x^2 \sin^2\phi \frac{\lambda\, s}{F}$$

For a vertical load, W, at the point $x = x'$, $z = \varepsilon\, x'$:

$$C_{11} = \frac{1}{2}\left[(L - x')\left(-\sum y \frac{s}{I} + h \sum \frac{s}{I}\right) + \sum_A^P x\, y \frac{s}{I} - x' \sum_A^P y \frac{s}{I} - h \sum_A^P x \frac{s}{I} + h\, x' \sum_A^P \frac{s}{I} + \varepsilon^2 \sum_A^P x^2 \sin\phi \cos\phi \frac{\lambda\, s}{F} - \varepsilon^2 x' \sum_A^P x \sin\phi \cos\phi \frac{\lambda\, s}{F}\right] W$$

$$C_{14} = \frac{1}{2}(L - x')\, W$$

$$C_{15} = \frac{1}{2}\left(1 - \frac{x'}{L}\right) W$$

For a horizontal load, H, at the point, $y = y'$, $z = \varepsilon x'$:

$$C_{11} = \frac{1}{2}\left[(h - y')\left(-\sum y \frac{s}{I} + h \sum \frac{s}{I}\right) + \sum_A^P y^2 \frac{s}{I} - y' \sum_A^P y \frac{s}{I} - h \sum_A^P y \frac{s}{I} + h\, y' \sum_A^P \frac{s}{I} + \varepsilon^2 \sum_A^P x^2 \sin^2 \phi \frac{\lambda\, s}{F} - \varepsilon^2 x' \sum_A^P x \sin^2 \phi \frac{\lambda\, s}{F}\right] H$$

$$C_{14} = \frac{1}{2} (h - y')\, H$$

$$C_{15} = \frac{1}{2} \left(\frac{h - y'}{L}\right) H$$

For temperature stresses:

$$C_{11} = C_1$$

Unsymmetrical Arches

For formulas to apply to the design of unsymmetrical arches, use Equations (20), (21), (25), and (27), as follows:

Stresses at a Section.—

$$t_v = - R_x \cos \phi - R_y \sin \phi + W \sin \phi - H \cos \phi \quad \text{(20a)}$$

$$t_u = - R_x \sin \phi + R_y \cos \phi - W \cos \phi - H \sin \phi \quad \text{(20b)}$$

$$t_z = R_z \quad \text{(20c)}$$

$$m_u = R_x\, \varepsilon\, x \cos \phi + R_y\, \varepsilon\, x \sin \phi + R_z\, v' - N_x \sin \phi + N_y \cos \phi - W\, \varepsilon\, (x - x') \sin \phi + H\, \varepsilon\, (x - x') \cos \phi \quad \text{(20d)}$$

$$m_v = - R_x\, \varepsilon\, x \sin \phi + R_y\, \varepsilon\, x \cos \phi - R_z\, u' - N_x \cos \phi - N_y \sin \phi - W\, \varepsilon\, (x - x') \cos \phi - H\, \varepsilon\, (x - x') \sin \phi \quad \text{(20e)}$$

$$m_z = R_x\, y + R_y\, x + N_z - W (x - x') + H (y - y') \quad \text{(20f)}$$

Co-Ordinates of the Right Abutment with Respect to Any Point, P.—

$$u' = x \sin \phi + y \cos \phi \quad \text{(21a)}$$

$$v' = x \cos \phi - y \sin \phi \quad \text{(21b)}$$

Final Equations for Unsymmetrical Fixed Arch (Origin of Co-Ordinates Is at Center of Right Abutment).—Here, again, the final equations are written in terms of the coefficients, K and C, for brevity:

$$- K_1 R_x + K_2 R_y + K_3 R_z + K_4 N_x - K_5 N_y = C_1 \quad \text{(25a)}$$

$$K_6 R_x - K_7 R_y + K_8 R_z + K_5 N_x + K_9 N_y = C_2 \quad \text{(25b)}$$

$$K_{10} R_x + K_{11} R_y + K_{12} N_z = C_3 \quad \text{(25c)}$$

$$K_{13} R_x + K_{14} R_y + K_{15} R_z + K_7 N_x + K_6 N_y + K_{10} N_z = C_4 \quad \text{(25d)}$$

$$K_{14} R_x + K_{17} R_y - K_{18} R_z - K_2 N_x - K_7 N_y + K_{11} N_z = C_5 \quad \text{(25e)}$$

$$- K_{15} R_x + K_{18} R_y + K_{19} R_z + K_3 N_x - K_8 N_y = C_6 \quad \text{(25f)}$$

in which, the coefficients for all loading and temperature stresses are:

$$K_1 = \varepsilon \sum x \sin\phi \cos\phi \frac{\lambda\, s}{F}$$

$$K_2 = \varepsilon \sum x \cos^2\phi \frac{\lambda\, s}{F}$$

$$K_3 = -\sum u' \cos\phi \frac{\lambda\, s}{F}$$

$$K_4 = -\sum \cos^2\phi \frac{\lambda\, s}{F}$$

$$K_5 = \sum \sin\phi \cos\phi \frac{\lambda\, s}{F}$$

$$K_6 = \varepsilon \sum x \sin^2\phi \frac{\lambda\, s}{F}$$

$$K_7 = \varepsilon \sum x \sin\phi \cos\phi \frac{\lambda\, s}{F}$$

$$K_8 = \sum u' \sin\phi \frac{\lambda\, s}{F}$$

$$K_9 = \sum \sin^2\phi \frac{\lambda\, s}{F}$$

$$K_{10} = \sum y \frac{s}{I}$$

$$K_{11} = \sum x \frac{s}{I}$$

$$K_{12} = \sum \frac{s}{I}$$

$$K_{13} = \sum y^2 \frac{s}{I} + \varepsilon^2 \sum x^2 \sin^2\phi \frac{\lambda\, s}{F}$$

$$K_{14} = \sum x\, y \frac{s}{I} - \varepsilon^2 \sum x^2 \sin\phi \cos\phi \frac{\lambda\, s}{F}$$

$$K_{15} = \varepsilon \sum u' x \sin\phi \frac{\lambda\, s}{F}$$

$$K_{16} = \varepsilon \sum x \sin^2\phi \frac{\lambda\, s}{F}$$

$$K_{17} = \sum x^2 \frac{s}{I} + \varepsilon^2 \sum x^2 \cos^2\phi \frac{\lambda\, s}{F}$$

$$K_{18} = \varepsilon \sum u' x \cos\phi \frac{\lambda\, s}{F}$$

$$K_{19} = -\sum u'^2 \frac{\lambda\, s}{F}$$

For vertical loading:

$$C_1 = \varepsilon \left[\sum_A^P x \cos^2\phi \frac{\lambda\, s}{F} - x' \sum_A^P \cos^2\phi \frac{\lambda\, s}{F} \right] W$$

$$C_2 = \varepsilon \left[-\sum_A^P x \sin\phi \cos\phi \frac{\lambda\, s}{F} + x' \sum_A^P \sin\phi \cos\phi \frac{\lambda\, s}{F} \right] W$$

$$C_3 = \left[\sum_A^P x \frac{s}{I} - x' \sum_A^P \frac{s}{I} \right] W$$

$$\begin{aligned} C_4 = \Bigg[\sum_A^P x\, y \frac{s}{I} - x' \sum_A^P y \frac{s}{I} + \varepsilon^2 \Bigg(-\sum_A^P x^2 \sin\phi \cos\phi \frac{\lambda\, s}{F} \\ + x' \sum_A^P x \sin\phi \cos\phi \frac{\lambda\, s}{F} \Bigg) \Bigg] W \end{aligned}$$

$$\begin{aligned} C_5 = \Bigg[\sum_A^P x^2 \frac{s}{I} - x' \sum_A^P x \frac{s}{I} + \varepsilon^2 \Bigg(\sum_A^P x^2 \cos^2\phi \frac{\lambda\, s}{F} \\ - x' \sum_A^P x \cos^2\phi \frac{\lambda\, s}{F} \Bigg) \Bigg] W \end{aligned}$$

$$C_6 = \varepsilon \left[\sum_A^P u' x \cos\phi \frac{\lambda\, s}{F} - x' \sum_A^P u' \cos\phi \frac{\lambda\, s}{F} \right] W$$

For horizontal loading:

$$C_1 = \varepsilon \left[\sum_A^H x \sin\phi \cos\phi \frac{\lambda\, s}{F} - x' \sum_A^H \sin\phi \cos\phi \frac{\lambda\, s}{F} \right] H$$

$$C_2 = \varepsilon \left[-\sum_A^H x \sin^2\phi \frac{\lambda\, s}{F} + x' \sum_A^H \sin^2\phi \frac{\lambda\, s}{F} \right] H$$

$$C_3 = \left[- \sum_A^H y \frac{s}{I} + y' \sum_A^H \frac{s}{I}\right] H$$

$$C_4 = \left[- \sum_A^H y^2 \frac{s}{I} + y' \sum_A^H y \frac{s}{I} + \varepsilon^2 \left(- \sum_A^H x^2 \sin^2 \phi \frac{\lambda s}{F} + x' \sum_A^H x \sin^2 \phi \frac{\lambda s}{F}\right)\right] H$$

$$C_5 = \left[- \sum_A^H x y \frac{s}{I} + y' \sum_A^H x \frac{s}{I} + \varepsilon^2 \left(\sum_A^H x^2 \sin \phi \cos \phi \frac{\lambda s}{F} - x' \sum_A^H x \sin \phi \cos \phi \frac{\lambda s}{F}\right)\right] H$$

$$C_6 = \varepsilon \left[\sum_A^H u' x \sin \phi \frac{\lambda s}{F} - x' \sum_A^H u' \sin \phi \frac{\lambda s}{F}\right] H$$

For temperature stresses (t ° rise):

$$C_1 = C_2 = C_3 = 0$$

$$C_4 = -2\, E\, c\, t\, L$$

$$C_5 = E\, c\, t\, a$$

$$C_6 = -2\, \varepsilon\, E\, c\, t\, L$$

All the summations are from A to B (Fig. 9) unless otherwise noted.

Final Equations for Unsymmetrical Two-Hinged Arch (Origin of Co-Ordinates Is at Center of Right Abutment).—

$$- K_1 R_x + K_2 R_y + K_3 R_z + K_4 N_x - K_5 N_y = C_1 \qquad \text{(27a)}$$

$$K_6 R_x - K_7 R_y + K_8 R_z + K_5 N_x + K_9 N_y = C_2 \qquad \text{(27b)}$$

$$K_{13} R_x + K_{14} R_y + K_{15} R_z + K_7 N_x + K_6 N_y$$
$$-\left(\frac{a}{2\, L}\right)(K_{14} R_x + K_{17} R_y - K_{18} R_z - K_2 N_x - K_7 N_y) = C_4 - \left(\frac{a}{2\, L}\right) C_5 \qquad \text{(27c)}$$

$$- K_{15} R_x + K_{18} R_y + K_{19} R_z + K_3 N_x - K_8 N_y = C_6 \qquad \text{(27d)}$$

$$R_y + \left(\frac{a}{2\, L}\right) R_x = C_7 \qquad \text{(27e)}$$

$$N_z = 0 \qquad \text{(27f)}$$

All the coefficients are the same as in Equation (26) for the fixed arch except C_7, which varies under different conditions as follows:

For vertical loading, W,

$$C_7 = \left(1 - \frac{x'}{2\, L}\right) W$$

For horizontal loading, H,

$$C_7 = \left(\frac{y'}{2\, L}\right) H$$

For temperature stresses,

$$C_7 = 0$$

Proportioning Sections

All the following equations are fully explained in Part II.

Relations Between Angles

$$\varepsilon' = \varepsilon \cos \phi \qquad \text{(28)}$$

$$\tan \phi' = \tan \phi \cos \theta \qquad \text{(29)}$$

Equations for Stresses per Unit Width of Arch

$$t_s = \frac{3}{2}\left(\frac{t_z - \varepsilon'\, t_v}{b}\right)\left(1 - \frac{4\,z^2}{b^2}\right) + \varepsilon'\,\frac{t_v}{b} + 12\,\varepsilon'\,\frac{m_u\,z}{b^3} \ldots\ldots (35)$$

$$t'_n = \varepsilon'\, t_s \ldots\ldots (36)$$

$$m_s = \frac{\varepsilon'\, m_z}{b} \text{ (at the face of bridge)} \ldots\ldots (43)$$

$$m_s = \frac{m_v + \varepsilon'\, m_z}{2\, b} \text{ (at any other point of the section)} \ldots\ldots (44)$$

$$m' = \frac{\varepsilon'^2\, m_z}{b} \text{ (at the face of bridge)} \ldots\ldots (48)$$

$$m' = \frac{\varepsilon'\, m_v}{b} \text{ (at any other point of the section)} \ldots\ldots (49)$$

$$V' = \frac{\varepsilon'\, t_u}{b} - \frac{8}{5}\,\varepsilon'\,\frac{(m_v - \varepsilon'\, m_z)}{b\, t} \text{ (at the face of bridge)} \ldots\ldots (51)$$

$$V' = \frac{\varepsilon'\, t_u}{b} \text{ (at any other point of the section)} \ldots\ldots (52)$$

Transformation Formulas

Equations (53*a*) and (53*b*) are general formulas:

$$\left.\begin{aligned} M &= m \sin^2\psi + m' \cos^2\psi + 2\, m_s \sin\psi\cos\psi \\ N &= t_n \sin^2\psi + t'_n \cos^2\psi + 2\, t_s \sin\psi\cos\psi \end{aligned}\right\} \ldots\ldots (53a)$$

$$\left.\begin{aligned} M_s &= (m' - m) \sin\psi\cos\psi + m_s (\sin^2\psi - \cos^2\psi) \\ S &= (t'_n - t_n) \sin\psi\cos\psi + t_s (\sin^2\psi - \cos^2\psi) \end{aligned}\right\} \ldots\ldots (53b)$$

They may be adapted to special cases in the following ways:

For Principal Moment Planes.—

$$\left.\begin{aligned} \tan 2\,\psi &= \frac{2\, m_s}{m' - m} \\ M &= \frac{m' + m}{2} \pm \frac{1}{2}\sqrt{(m' - m)^2 + 4\, m_s^2} \end{aligned}\right\} \ldots\ldots (53c)$$

$$\left.\begin{aligned} \psi &= 90 - \theta' \\ M &= m \sec^2\theta' \end{aligned}\right\} \text{ (at the face of bridge)} \ldots\ldots (53d)$$

For Principal Thrust Planes.—

$$\left.\begin{aligned} \tan 2\,\psi &= \frac{2\, t_s}{t'_n - t_n} \\ N &= \frac{t'_n + t_n}{2} \pm \frac{1}{2}\sqrt{(t'_n - t_n)^2 + 4\, t_s^2} \end{aligned}\right\} \ldots\ldots (53e)$$

$$\left.\begin{aligned} \psi &= 90 - \theta' \\ N &= t_n \sec^2\theta' \end{aligned}\right\} \text{ (at the face of bridge)} \ldots\ldots (53f)$$

For Maximum and Minimum Torsion Moment.—

$$\left.\begin{aligned} \tan 2\,\psi &= \frac{m - m'}{2\, m_s} \\ M_s &= \pm\,\frac{1}{2}\sqrt{(m' - m)^2 + 4\, m_s^2} \end{aligned}\right\} \ldots\ldots (53g)$$

For Maximum and Minimum Shearing Thrust.—

$$\left.\begin{aligned} \tan 2\,\psi &= \frac{t_n - t'_n}{2\, t_s} \\ S &= \pm\,\frac{1}{2}\sqrt{(t'_n - t_n)^2 + 4\, t_s^2} \end{aligned}\right\} \ldots\ldots (53h)$$

FINAL DESIGN FORMULAS (EQUATIONS (64))

CASE I.—SIMPLE BENDING; STEEL IN ONE DIRECTION, IN THE INTRADOS FACE ONLY (SEE FIG. 30).

		(*A*) Tension over part of section containing steel.	(*B*) Compression over entire section.	(*C*) Tension over part of section not containing steel.	Equations (64).
$f_s p \cos^2 \alpha$	=	$\frac{1}{2} f_c k$	$\frac{1}{2} f_c (2-q) \frac{t}{d}$	$\frac{1}{2} f_c k$	(*a*)

q_s*	=	$\frac{3 + 6 j_s - 6\frac{d}{t}}{2 + 3 j_s - 3\frac{d}{t}}$	(*i'*)
$\frac{f_s}{n}$	=	$\sum f_c a \cos^2 \alpha + \lambda h a_s \sin \alpha \cos \alpha$	(*j*)
$\frac{1}{2pn}$	=	$\sum c \cos^4 \alpha + \lambda c_s \sin^2 \alpha \cos^2 \alpha$	(*k*)

---

*If in any of the equations, $q_s = 2$, and $j_s = \infty$, that equation becomes indeterminate. By differentiation, it can be reduced to a determinate value: $\pm \frac{6 M_s}{b t^2} = h$, which means that the resultant is a couple.

DISCUSSION

G. D. HOUTMAN,[9] ASSOC. M. AM. SOC. C. E. (by letter).—This paper is without doubt a valuable and timely contribution to the science of skew arch design. It is founded, among other things, on the elastic theory.

This theory is known to apply almost perfectly (up to a certain point), to a steel beam. It applies with less accuracy to a concrete beam, and with still less precision to a narrow arch rib. Presumably, it is even less applicable to a wide skew arch, involving elastic deformations within cross-sections of considerable area. Granting that a concrete section, 1 ft. wide and 3 ft. deep, bends elastically, there is no positive assurance that another section 3 by 60 ft. will bend the same way. A low building can be erected safely perhaps on a shifty foundation, but one need not trust altogether the mathematical skyscraper built on a somewhat sandy base. At the same time, the art of design has always advanced by such steps as these, and the author is entitled to commendation for his paper.

It seems to the writer that skew arches can be explained and designed with much more simplicity by a method which is frankly approximate. Let the problem be, for instance, to design the skew arch, *A B C D,* in Fig. 36. The first step would be to design, by any method, a rectangular arch of the same longitudinal span and the same width, that is, the arch, *A B′ C′ D.* This rectangular arch is next conceived to be distorted into the skew arch, *A B C D.*

The next step consists in applying the principle of least work. It is well known that Nature is economical of its efforts, and that accordingly structures act and deflect in such a way that the work done is a minimum. Obviously, the least work is done when the compression paths are of least length, and as straight as possible. There surely would be more work done in carrying a load by a roundabout or longer path. Such being the case, the skew arch, *A B C D,* tends to divide itself into a central rectangular arch, *E B F D,* and two triangular arches, *A E D* and *C F B.* There is nothing mysterious about the central rectangular arch, *E B F D.* Regarding the triangular arches, any compression path emanating from the line, *F C,* converges upon the point, *B,* which is the

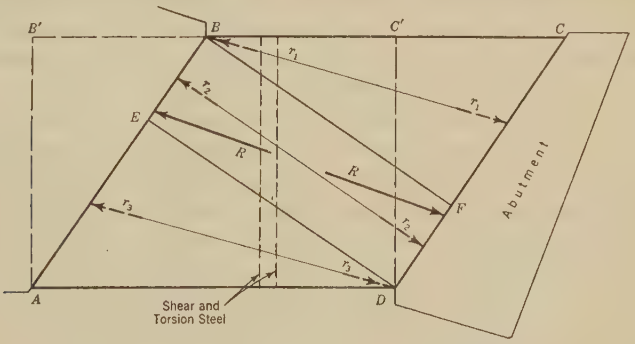

FIG. 36.—APPROXIMATE ANALYSIS OF A SHEAR ARCH

nearest point to any other point on the line, *F C*. The same reasoning applies to the other triangular arch, *A E D*, which is similar in all respects.

---

[9] Designing Engr., County Engr.'s Office, Delaware County, Media, Pa.

Next, bisect each of the three arches with fine lines, at the extremities of which draw the three resultants, r_1, r_2, and r_3 ($= r_1$). The lengths of these three resultants are made proportional to the plan areas of their respective arches. Thus, r_1 is proportional in length or magnitude to the area, *B C F*, and r_2 is proportional to the area, *E B F D*. These three resultants are next combined to compose the final resultant, *R*. At present, this resultant is established as to direction and point of application, but not as to magnitude. It will be on the safe side to assume that its magnitude is equal to that of the total resultant acting on the center of line, *A B′*, in the original design of the rectangular arch, *A B′ C′ D*.

It is frankly acknowledged at this point that the procedure expounded in the preceding paragraph is not altogether correct, even if it possesses the virtue of simplicity. For instance, the magnitude of r_1 should be somewhat less than assumed herein, and, in reality, its point of application should be closer to the point, *C*, than to the point, *F*. There is also something to say regarding the different ratios of vertical to horizontal components.

The position and magnitude to the final resultant, *R*, determine the magnitude and distribution of stress along the abutment face, *D C*. Obviously, the compression stresses are greatest at *D* and least at *C*. In fact, tension may be indicated at *C*. If the compressive stresses at *D* are excessive, the arch can be thickened near that point, or, perhaps, a richer mix can be specified. The abutment is given a trapezoidal shape.

A triangular arch, such as *A E D*, obviously could not exist by itself, because the point, *D*, has no strength. It can exist only in conjunction with a neighboring arch, to which the thrust which the apex, *D*, cannot take, is transmitted by shear along the shear plane, *E D*. As far as the determination of the final resultant, *R*, is concerned, r_3 acts as shown; but it is necessary to place enough transverse steel at right angles to the longitudinal center line, to transmit the thrust, r_3, into the intermediate section.

The arch axis of each triangular arch is probably a symmetrical curve, such as a parabola or circular arc. The corresponding thrust line, however, would not be a symmetrical curve, since there is more load on one side than on the other, of the vertical center line. Hence, the thrust line departs from the arch axis in the triangular arch. Since one such arch is the reverse of the other, certain torsional stresses are induced. Other torsional stresses are caused when the arch, for any reason, such as temperature, rib-shortening, etc., is distorted, lengthened, or shortened. The writer believes however that these torsional stresses need give no concern, provided that conservative design stresses are used and that the arch contains somewhat more than the customary amount of longitudinal and transverse steel.

Some existing textbooks state that skew arches can be designed exactly as square arches. This assertion is known to be erroneous, but it must be admitted that a large number of skew arches have been built in complete ignorance of skew principles, and that only a few have failed. Usually, failure has resulted from excessive compression at the obtuse corner, and a cracking off of a section of abutment. There have been failures during construction caused by insufficient bracing of the centering. In general, the falsework of a skew arch should be braced three ways instead of the customary two. Of the existing skew arches which were designed as rectangular arches, some show peculiar cracks which indicate tension, or, at least, absence of compression, at the acute corner. Intermediate piers between skew arches are full of danger, since the skew thrusts tending to spin them about a vertical axis are doubled.

J. CHARLES RATHBUN,[10] M. AM. SOC. C. E. (by letter).—The writer has been much interested in Mr. Weiner's description of the methods of analyzing skew arches as practiced by the Westchester County Park Commission. The paper is valuable not only as a description of methods, but also because it brings the theory before the profession in a slightly different form from that used in its first presentation.[11] The numerous integral signs used in the writer's paper may have led to difficult reading for those who are more accustomed to the sigma sign for summation.

In the writer's opinion, the principal value of Mr. Weiner's paper is that it calls the attention of the profession to the fact that arches are being built successfully by this theory. When it was first published some question was raised as to the correctness of the mathematics. It was popularly believed that the stress distribution at the abutment was greatest at the obtuse corners, and when the equations failed to substantiate this idea they were not accepted by conservative members of the profession. Later, very careful and extensive experiments (unpublished) were conducted by George E. Beggs, M. Am. Soc. C. E., for the Society's Special Committee on Concrete and Reinforced Concrete Arches. The results of computations of all six abutment reactions for each of four different arches for a vertical load in a large number of positions showed substantial agreement with the results of these tests. As the report of this work for the Committee may not have been brought to the attention of all who have been interested in the subject, Mr. Weiner's paper brings before the public the fact that this method of analysis is a safe one to follow.

In discussing the changes in practice from the original, as introduced by Mr. Weiner, the writer does not feel that these changes seriously affect any results in the final design, but are simply differences in personal practice; or, as in the use of a sigma instead of an integral sign, the difference between a theoretical formula and its practical application. Some of the suggestions, such as the use of coefficients for Equations (25), K_1, K_2, etc., and the dropping of terms of low value will occur readily to any designer.

The practice of dropping terms of low value should be treated with great caution. Those terms that are dropped in analyzing one arch, may be important in another. For example, the arches designed by Arthur G. Hayden, M. Am. Soc. C. E., for Westchester County, will permit the omission of all terms containing the moment of inertia about the u-axis and these have been dropped by Mr. Weiner. These terms are indeed very small in barrel arches, but they have a great influence in arch ribs. The writer, therefore, considers it wise for an engineer who is designing a skew arch to study the question of omitting terms as it applies to his own problem. He may find an entirely different solution than the one given. The writer also was guilty of this practice in his paper,[12] although the equations as developed are found in full in the Appendix of that paper. The same idea may be extended to some of the other "short cuts".

---

[10] Associate Prof. of Civ. Eng., Coll. of the City of New York, New York, N. Y.

[11] *Transactions*, Am. Soc. C. E., Vol. LXXXVII (1924), p. 611.

A designer who has familiarized himself with the original theory may find some confusion in the notation in several places in Mr. Weiner's paper. It would be less confusing to have retained the writer's original notation as nearly as possible. For example R_x, R_y, and R_z, are used as deflections due to loads by the writer while Mr. Weiner uses them as abutment reactions. The introduction of θ for the writer's $\tan^{-1} \varepsilon$, in one place, and his Δ_α, Δ_β, Δ_γ, in another, might cause confusion.

The writer has found the change of signs suggested by Mr. Weiner very confusing and does not see what is to be gained by it. The sign convention introduced by the writer in his paper are self-consistent, and an engineer who follows these equations need fear no confusion. The sign of T_y was taken in the direction indicated because it is consistent with current practice in representing shear in beam analysis, and an arch approaches the beam in many cases. As it is customary to indicate positive shear in the manner shown, it is confusing to change it. If the arch tends toward the flat type the designer should not be confused by his familiarity with the beam theory. A change in the sign of the shear forces makes them inconsistent with the idea that the differential moment is a shear. The change of sign of T_y and sometimes of M_y and T_z is not wise. If familiarity with the figures of a skew as shown in Fig. 2(*a*) makes it easier for an engineer to keep his work more clearly in mind, there is no mathematical objection to computing an arch as there shown, and after the work is completed sketching the results as in Fig. 2(*b*). This will avoid using a term at times as plus and at other times as minus.

Another change that has been made, which has several disadvantages, is in the order of the equations. This appears, for example, in Mr. Weiner's equations for the solution of the unsymmetrical skew (Equations (25)). He is in error in his statement in the "Introduction" that "the theory as presented applied only to symmetrical skew frames fixed at the abutments". Much of the space in the paper devoted to the original theory, applied to the simplification of the equations due to the symmetry of the ring, but the theory as presented has been used by the writer without change for skews. If this symmetry does not exist the writer fails to see how the six equations (Equations (25)) given by Mr. Weiner, or those given previously by the writer,[13] can be simplified. Possibly the solution lies along the lines suggested by Carl B. Andrews, Assoc. M. Am. Soc. C. E.[14]

[14] *Loc. cit.*, p. 438.

Because Equations (29) of the writer's paper[13] supply the missing terms that may prove necessary in some designs they are here stated in Equations (74) in terms of the writer's notation.

The signs, order of equations, and form of integrals have been retained as in the original paper. Note that the coefficients, K, are symmetrical relative to rows and columns. Mr. Weiner assumed the position of the load such that $z' = \epsilon x'$.

$$K_{13}\,T_x + K_{14}\,T_y + K_{15}\,T_z + K_{10}\,M_z + K_6\,M_y + K_7\,M_x = C_4 \ldots\ldots (74a)$$

$$K_{14}\,T_x + K_{17}\,T_y + K_{18}\,T_z + K_{11}\,M_z + K_7\,M_y + K_2\,M_x = C_5 \ldots\ldots (74b)$$

$$K_{15}\,T_x + K_{18}\,T_y + K_{19}\,T_z + K_8\,M_y + K_3\,M_x = C_6 \ldots\ldots (74c)$$

$$-C_3 = -\left\{\int_A^P \times \frac{ds}{I_z}\right\} W + \left\{\int_A^P \frac{ds}{I_z}\right\} W x'$$

$$-C_2 = \left\{\varepsilon \int_A^P \left(\frac{1}{I_y} - \frac{\lambda}{F}\right) x \sin\phi\cos\phi\, ds\right\} W - \left\{\int_A^P \left(\frac{1}{I_y} - \frac{\lambda}{F}\right) \sin\phi\cos\phi\, ds\right\} W z'$$

$$-C_1 = \left\{\varepsilon \int_A^P x \sin^2\phi \frac{ds}{I_y} + \varepsilon\lambda \int_A^P x \cos^2\phi \frac{ds}{F}\right\} W - \left\{\int_A^P \sin^2\phi \frac{ds}{I_y} + \lambda \int_A^P \cos^2\phi \frac{ds}{F}\right\} W z'$$

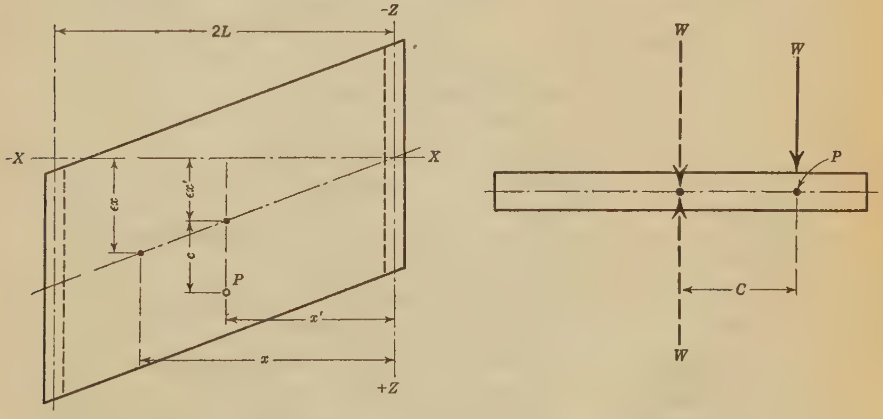
Equations (74) give the deflection of a skew cantilever under load and with end reactions. In the case of a skewed arch with fixed ends these deflections should be placed equal to zero and the end or abutment reactions computed.

Often the unsymmetrical skew arch has some degree of symmetry as will occur when the ring is symmetrical from the crown to the legs (in the case of an arch of the type used by Mr. Hayden); but when the legs have different lengths, or otherwise are not symmetrical, the theory as originally written can be applied, except that many of the terms that will cancel in the symmetrical arch must be retained, as there stated.

In the development of the unit stresses Mr. Weiner has used a different distribution for torsional stresses. Otherwise, it is fundamentally the same as that used by the writer for several years. It might be of interest to know the difference in results between these equations, especially as Mr. Weiner states in the "Introduction" that he has compared the several theories numerically. The matter of torsional stress distribution is a very vital part of this work in many cases.

Although the writer's discussion may appear to indicate that he differs from the author, in closing he wishes to state that his criticisms are all very minor and are given for the purpose of improving a very excellent paper. Mr. Weiner is especially to be commended in proving the correctness of the method of computing the unit stresses from the forces acting across a section.

A. A. EREMIN,[15] ASSOC. M. AM. SOC. C. E. (by letter).—The author has presented an extremely interesting paper on the design of a skew arch and "rigid frame." He has simplified the equations originally developed[16] by J. Charles Rathbun, M. Am. Soc. C. E., and has illustrated their application by a practical design problem.



(a) PLAN

(b) SECTION

FIG. 37.—DIAGRAM SHOWING POSITION OF UNSYMMETRICAL CONCENTRATED LOAD.

The equations for a skew arch with the loads symmetrical about the center line between spandrel walls, are discussed in this paper. For the stresses in a skew arch with unsymmetrical concentrated loads the equations will be slightly different.

---

[15] Asst. Designing Engr., Bridge Dept., State Highway Comm., Sacramento, Calif.

[16] *Transactions*, Am. Soc. C. E., Vol. LXXXVII (1924), p. 611.

Fig. 37(*a*) is the plan of a skew arch with a concentrated load, *W*, at the point, *P*. The eccentricity is designated by *c*. The elevation of the arch is the same as that shown in the author's Fig. 9(*b*). This unsymmetrical load may be replaced by a symmetrical load, *W*, and a moment, W_c. Then the equations for the moments will be:

$$m_u = R_x \epsilon x \cos\phi + R_y \epsilon x \sin\phi + R_z v' - N_x \sin\phi + N_y \cos\phi$$
$$- W \epsilon (x - x') \sin\phi - W_c \sin\phi \text{ ....} (75d)$$

$$m_v = - R_x \epsilon x \sin\phi + R_y \epsilon x \cos\phi - R_z u' - N_x \cos\phi - N_y \sin\phi$$
$$- W \epsilon (x - x') \cos\phi - W_c \cos\phi \text{.................} (75e)$$

and,

$$m_z = R_x y + R_y x + N_z - W (x - x') \text{..............} (75f)$$

The reactions at the arch may be obtained from the final equations:

$$- K_1 R_x + K_2 R_y + K_3 R_z + K_4 N_x - K_5 N_y = C_1 \text{........} (76a)$$
$$K_6 R_x - K_7 R_y + K_8 R_z + K_5 N_x + K_9 N_y = C_2 \text{........} (76b)$$
$$K_{10} R_x + K_{11} R_y + K_{12} N_z = C_3 \text{........} (76c)$$
$$K_{13} R_x + K_{14} R_y + K_{15} R_z + K_7 N_x + K_6 N_y + K_{10} N_z = C_4 \text{........} (76d)$$
$$K_{14} R_x + K_{17} R_y - K_{18} R_z - K_2 N_x - K_7 N_y + K_{11} N_z = C_5 \text{........} (76e)$$
$$- K_{15} R_x + K_{18} R_y + K_{19} R_z + K_8 N_x - K_8 N_y = C_6 \text{........} (76f)$$

in which, the coefficients, *K*, are as given by the author, in Equations (25), Appendix I, and the coefficients, *C*, are:

$$C_1 = \epsilon \left[\sum_A^P x \cos^2\phi \frac{\lambda s}{F} - x' \sum_A^P \cos^2\phi \frac{\lambda s}{F} \right] W + Wc \sum_A^P \cos^2\phi \frac{\lambda s}{F}$$

$$C_2 = \epsilon \left[- \sum_A^P x \sin\phi \cos\phi \frac{\lambda s}{F} + x' \sum_A^P \sin\phi \cos\phi \frac{\lambda s}{F} \right] W$$
$$- Wc \sum_A^P \sin\phi \cos\phi \frac{\lambda s}{F}$$

$$C_3 = \left[\sum_A^P x \frac{s}{I} - x' \sum_A^P \frac{s}{I} \right] W$$

$$C_4 = \left[\sum_A^P x y \frac{s}{I} - x' \sum_A^P y \frac{s}{I} + \epsilon^2 \left(- \sum_A^P x^2 \sin\phi \cos\phi \frac{\lambda s}{F} \right. \right.$$
$$\left. \left. + x' \sum_A^P x \sin\phi \cos\phi \frac{\lambda s}{F} \right) \right] W - W c \epsilon \sum_A^P x \sin\phi \cos\phi \frac{\lambda s}{F}$$

$$C_5 = \left[\sum_A^P x^2 \frac{s}{I} - x' \sum_A^P x \frac{s}{I} + \epsilon^2 \Bigg(\sum_A^P x^2 \cos^2\phi \frac{\lambda s}{F} \right.$$
$$\left. - x' \sum_A^P x \cos^2\phi \frac{\lambda s}{F} \right] W + W c \epsilon \sum_A^P x \cos^2 \frac{\lambda s}{F}$$

$$C_6 = \epsilon \left[\sum_A^P u' x \cos\phi \frac{\lambda s}{F} - x' \sum_A^P u' \cos\phi \frac{\lambda s}{F} \right] W$$
$$+ W c \sum_A^P u' \cos\phi \frac{\lambda s}{F}$$

The notation and initial assumptions are the same as those used by Mr. Weiner. If the eccentricity is zero, the coefficients, C, will be the same as given by the author in Equations (25), Appendix I, for the arch with symmetrical loads. For a more exact computation the neglected terms in Equations (75) and (76) may be obtained as shown by Professor Rathbun.[16]

If the abutments of a skew arch are likely to move due to the initial stresses, the error in computing the reactions depends upon the assumptions of the abutment displacements in six co-ordinates. The stress analysis may be simplified by introducing hydraulic jacks at the crown during construction, as shown in Fig. 38. Some of the unknown stresses at the crown may be eliminated by properly detailing the jack bearings. Moreover, the arch may be pre-stressed to almost any desirable condition by assuming a temporary load.

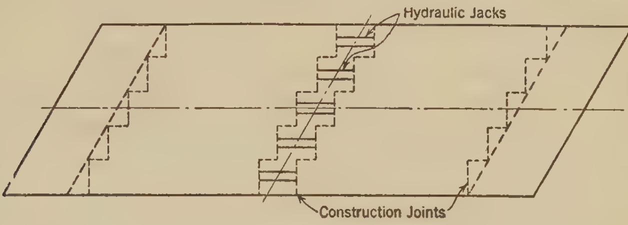


FIG. 38.—PLAN SHOWING HYDRAULIC JACKS METHOD OF POURING SKEW ARCH

It should be noted that a considerable departure from the fundamental requirements of the elastic theory of the statically indeterminate structures is made in applying the skew arch equations to the "rigid frame." This is due to the nearly right-angle corners in the neutral axis of the frame shown in Fig. 29.

For a rigid scientific analysis of stress distribution in a skew arch it has not yet been sufficiently proved that the effect of shear stresses at the sharp corner of a section, Fig. 12(*b*), will be carried uniformly over the entire width. Bearing in mind the elastic properties of concrete, it is more likely that the angle, θ (Fig. 14), decreases rapidly from the face toward the middle of the section.

The design of construction joints has tremendous influence on stress distribution in a skew arch. Experimental tests[17] with a hard rubber model of a skew arch has shown a symmetrical distribution of stresses due to the horizontal thrust parallel to spandrel walls and to the vertical reactions. This fact may be utilized in designing saw-toothed construction joints normal to the neutral axis in the arch and abutments, as shown in Fig. 38.

Numerous assumptions were made in these equations for stresses in a skew arch in order to simplify them and, therefore, experimental tests with models of a fairly large scale should be made to determine the magnitude of the errors introduced.

---

[17] *Engineering News-Record,* July 21, 1927, p. 106.

The author has performed a laborious task in presenting this contribution to the theory of skew arch design, and further tests are needed before conclusive statements can be made.

Bernard L. Weiner,[18] Assoc. M. Am. Soc. C. E. (by letter).—In engineering literature too little attention is given to the study of internal stress distribution. The design of any structure may be divided into two parts:

(1) The computation of the reactions, and from the reactions, the determination of the total moments, thrusts, and shears acting at the critical sections of the structure.
(2) The determination of the distribution of the unit stresses produced by the total stresses, in order that the sections may be proportioned to resist the total moments, thrusts, and shears within the allowable unit stresses.

Much has been written on the first step, but rather scant attention has been paid to the second step. Scientific analysis has been replaced repeatedly by more or less arbitrary assumptions, yet the mathematical tools necessary for the proper analysis are in many cases available. Even for the case of the straight beam for which the formulas, $f = \frac{Mc}{I}$, and $v = \frac{VQ}{bI}$, apply, the unnecessary assumption is usually made that a plane section before bending remains a plane after bending. In this case, that assumption happens to be true, but it would be more scientific to prove it rather than merely to assume it. The proof also happens to be simple. What is true of structures, in general, is also true of the skew arch, in particular.

In 1924, J. Charles Rathbun, M. Am. Soc. C. E., published his masterly exposition of the analysis of the skew arch.[19] About two years later he revised and completed his theory as consultant for the Westchester County Park Commission. This theory formed the basis of Part I of the writer's paper; but this work concerned itself almost entirely with the first step; that is, it gave a method, or rather a mathematical theory, for computing the total moments, thrusts, and shears acting on any section of a skew frame. The second step was touched upon both in the report to the Commission and in correspondence with Professor Rathbun. The suggested treatment of the second step was entirely inadequate and scientifically unsound. The result of the writer's study of this part of the subject is given in Part II. Similar studies can profitably be made for many other types of structures, which are still designed more or less arbitrarily.

Such criticism as has been published deals only with Part I. The writer is rather disappointed on this account for he had hoped that criticism of Part II would bring to light valuable information on the theory of internal stresses, especially on the subject of torsion in reinforced concrete.

Mr. Houtman doubts the validity of Professor Rathbun's theory of skew arches when applied to a wide arch. This part of the theory can scarcely be considered open to reasonable doubt as it has been substantiated by tests on models. These tests were made by Professor Rathbun on plaster models,[20] and by George E. Beggs, M. Am. Soc. C. E., on hard rubber models,[21] and they check closely with the results obtained by computation. More recently, Professor Rathbun made similar tests on a plaster model of a multiple-span skew arch.[22] For design purposes, at least, the skew arch theory for obtaining the reactions, seems to be adequate beyond reasonable doubt.

---

[18] New York, N. Y.

[19] *Transactions*, Am. Soc. C. E., Vol. LXXXVII (1924), p. 611.

The writer fails to see the logic of Mr. Houtman's method of analyzing a skew arch. No proof whatever is given for the various statements, except some rather vague references to the theory of least work. Referring to Fig. 36, he says, "there is nothing mysterious about the central rectangular arch, *E B F D*." As a matter of fact, there is a great deal of mystery about this arch. For instance, it is not all clear how the vertical shears acting on the vertical surfaces, *D E* and *B F*, are taken into account. Reference to Part II of the writer's paper, will show that there are also a horizontal shear, a thrust, and a bending moment—the values of which per unit length are variable—acting on these surfaces. It is also not clear what the relation is between the analysis of the right arch, *A B′ C′ D*, and that of the skew structure, or why it is on the safe side to assume that the resultant, *R*, is equal to the resultant of this right arch. Furthermore, Fig. 36 may be redrawn so that the central right arch, *E B F D*, disappears entirely, as shown in Fig. 39. Following Mr. Houtman's method, the problem is changed from the design of one skew arch, to that of a smaller skew arch and two triangular arches. Fig. 39 may even be drawn so that the lines, *B F* and *D E*, will coincide. In this case two arches which cannot support themselves will have to support each other. This method of analysis will not bear close scrutiny.

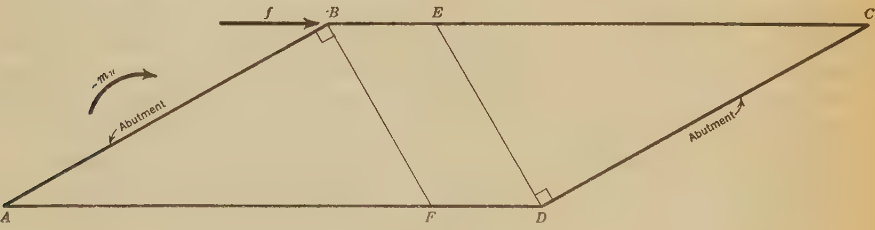

FIG. 39.

It is true that skew arches have been designed and built in entire ignorance of skew-arch principles and that only a few have failed. Of those that have not failed, nothing is known about their factors of safety, nor is anything known about their economy of design. Mr. Houtman stated that "usually failure resulted from excessive compression at the obtuse corner * * *." In view of the skew arch theory, the correctness of this diagnosis is doubtful. The prevailing opinions regarding the intensity of the compression at the obtuse corner seem to be very much exaggerated. In the writer's notation, the moment which causes this compression is m_u. Referring to Table 8 of the main paper, the dead load value of this moment is − 2 071 kip-ft. and acts as shown in Fig. 39.

---

[20] "Crown Stresses in a Skew Arch," *Transactions*, Am. Soc. C. E., Vol. 94 (1930), p. 135.

[21] *Loc. cit.*, Vol. 88 (1925), p. 1208.

[22] "An Analysis of Multiple-Skew Arches on Elastic Piers," Part IV, *Proceedings*, Am. Soc. C. E., April, 1931, Papers and Discussions, p. 539.

The stress, f, treating the arch as an unreinforced beam, is, in pounds per square inch:

$$f = \pm \frac{6\ m_u}{6^2\ t} \sec^2 \theta = \pm \frac{6 \times 2\,071\,000 \times 12}{(66.9)^2 \times 144 \times 54} \times 2.42 = \pm\ 10.35$$

The numerical value of this moment is large, but since the entire width of the arch acts as the depth of a beam to resist it, it follows that the resulting unit stress is small. Furthermore, the peculiar cracks at the acute corners of existing skew arches, to which Mr. Houtman refers, can scarcely be due to tension because of skew arch action, since the longitudinal reinforcement which is designed to resist the ordinary bending moment, M_z, will take up this tension in the action of the arch as a beam the depth of which is the width of the structure. Furthermore, it has just been shown that the estimates of the intensity of this tension are probably much exaggerated.

It is well to point out in this connection, that if the arch is poured in longitudinal strips, care must be taken that each section be well keyed in to the adjacent section by both horizontal and vertical keys, in order to provide adequate shear resistance. Lack of such shear resistance, of course, will destroy the ability of the arch to act as a single beam of depth, b (skew width of the arch).

In the second paragraph of his discussion, Professor Rathbun uses the expressions, "this theory," and "this method of analysis," rather loosely. What Professor Rathbun is referring to is his own theory for obtaining the abutment reactions (and from them the total stresses at any other section), which is given in a revised form in Part I of the writer's paper. The tests mentioned, prove only one thing; that is, that the relation between the loads and the reactions is correct. The tests prove this, and no more; but as the writer stated in the beginning of this discussion, this is only one of two steps in any complete analysis. It is easy enough to find the reactions in a simple I-beam, and also the maximum moment and shear; but this would be of little value in finding the unit stresses if one did not know that $f = \frac{My}{I}$, and that $v = \frac{VQ}{bI}$. Professor Rathbun made a slight and very unsuccessful attempt to solve the second and equally important part of the problem.

Toward the end of his discussion, Professor Rathbun states:

> "In the development of the unit stresses, Mr. Weiner has used a different distribution for torsional stresses. Otherwise, it is fundamentally the same as that used by the writer for several years."

The writer must take issue with Professor Rathbun on this point. He has been familiar with Professor Rathbun's method of stress distribution[23] for some years and disagrees entirely with that method. Obviously, since Professor Rathbun devotes only about four pages to his method, and the writer has thought it necessary to devote about sixty pages to this part of the subject (which forms Part II of his paper), there must be some fundamental difference between the two theories. The results obtained by the use of the two methods are radically different.

---

[23] "An Analysis of Multiple-Skew Arches on Elastic Piers," Pt. II, *Proceedings*, Am. Soc. C. E., April, 1931, Papers and Discussions, p. 524.

In this discussion it is not necessary to go into the differences between the theory of unit stress distribution as given in Part II and Professor Rathbun's method to which reference has been given. To do so would be mere repetition. Some of the more vital points have been discussed by the writer[24] in his criticism of the aforementioned paper by Professor Rathbun. Suffice it to say that the difference in the torsion formula used is only of minor importance. As the writer has remarked several times, the subject of torsion in reinforced concrete is still an open question; and much work remains to be done in this connection. Furthermore, in his development of the theory for proportioning the sections, the writer has given ample proof for each individual step and has not relied on mere assumption. The comparison, therefore, can be easily made by the interested reader.

As pointed out in the reply to Mr. Houtman's discussion, there is a difference of stress between the obtuse corner and the acute corner of the abutment, and the stresses are compression and tension, respectively. The general opinion as to the magnitude of this stress, however, is exaggerated, as shown by the numerical example which gives an indication of the range of the magnitude of these stresses. Professor Rathbun is in error in stating that his equations do not substantiate this belief. This belief is correct as to the presence of the stress, but not as to its magnitude.

In his discussion of Part I, Professor Rathbun is correct in stating that the practice of dropping terms of low values should be treated with caution. The writer expressed the same idea in his paper, and stated specifically that the question should be looked into carefully by the designer.

Professor Rathbun does not see what is to be gained by the changes in his part of the theory. The writer used Professor Rathbun's unrevised manuscript for a period of about two years. Blue-print copies were furnished by A. G. Hayden, M. Am. Soc. C. E., to many bridge designers all over the United States and abroad. It was found after this period of trial that, for one thing, the system of signs was very confusing and difficult to remember. Constant reference had to be made to the table of nomenclature in order to interpret the signs of the stresses in terms of actual directions. Professor Rathbun referenced his system of co-ordinate axes and his system of signs to directions in space, with the result that forces and moments changed signs with the direction of the skew for the same type of loading. The writer referenced his system to the actual structure, with the result that the stresses for the same type of loading always had the same sign. Furthermore, the sign system was organized in order to make it easier to remember. It was not a question of mathematical correctness, but one of practical convenience.

---

[24] *Proceedings*, Am. Soc. C. E., September, 1931, Papers and Discussions, p. 1107.

Professor Rathbun errs in saying that the direction of T_y makes it inconsistent with the idea that the derivative of the moment is the shear, and that it is inconsistent with the definition of shear in simple beams. The common definition of the vertical shear in a simple beam would make T_y act as shown in Figs. 4 and 5. Furthermore, from the equations it follows directly that $\frac{\partial m_z}{\partial v} = t_u$, and this expression is introduced several times in Part II. As a matter of fact, it would make no difference if the direction of the shear, T_y (t_u), were reversed. The most serious consequence would be that $\frac{\partial m_z}{\partial v}$ would equal $- t_u$. This might perhaps be inconvenient, but not incorrect. It might also be pointed out that Professor Rathbun, too, is guilty of using double signs for T_y and M_y. This is not caused by the direction of the stresses, but by the simplification made on account of symmetry, and applies only to symmetrical arches. He is in error, however, in including T_z in this category.

Mr. Eremin is correct in adding the terms containing Wc for eccentric loading. The reactions thus obtained for this type of loading would undoubtedly be correct; but whether this would be of any practical value at present is questionable, because the problem of concentrated load distribution would then have to be taken into consideration. This problem is not confined only to the skew arch; it is present also in the right arch. It is a question whether a single line of trucks near the curb of a bridge might not perhaps produce greater stresses at some points than are obtained for the bridge fully loaded.

In his discussion[24] of Professor Rathbun's paper on "Multiple-Skew Arches," the writer has pointed out that the tests made by E. F. Gifford, Assistant Engineer in the Engineering Department of the New York Central Railroad, showed in general that for eccentric loading there are two types of failure: (1) A local failure in the immediate vicinity of the load; and (2), a general failure at points far enough away from the load so as not to be affected by the local load distribution stresses.

For sections where the maximum moments occur with the load at the section, the local load distribution stresses become important since so little is known about them. For this reason knowing the correct reactions for eccentric loading does not help a great deal. Here, again, the all-important question of internal stress distribution enters, and even though the total stresses are available, the unit internal stresses still remain a mystery For the sake of completeness, it is well to include the terms representing the eccentricity of the load and the writer is grateful to Mr. Eremin for pointing this out and for supplying the missing terms.

The application of the skew arch equations to a rigid frame is not a departure from the fundamental requirements of the elastic theory, except that the stresses at the corners are unknown. For the right rigid frame the effect of the corner on the stresses in general has been found to be negligible by comparing the analytical results with those obtained by use of the Beggs' deformeter gauges. Before the first rigid frame was built, the corner was tested for strength, and it was found that failure occurred everywhere, except at the sharp corners where it was predicted.

Mr. Eremin is in error in his interpretation of Fig. 12(*b*) and Fig. 14. These two diagrams, as well as Equations (30), (31), and (32), apply only to the face of the bridge. Nothing is said at this point about the value of the unit shear toward the middle of the bridge. Mr. Eremin is correct in surmising that the shear at the sharp corner of the section is probably not carried uniformly across the section. This is proved by Equations (35) which give the value of the unit horizontal shear at any point of the section, and similar proofs are given for the vertical shear and shear moment per unit width. The angle, θ, does not vary since it is the skew angle. What Mr. Eremin has in mind is the angle, ψ, which gives the direction of the resultant stress at any point. At the face of the bridge where Fig. 12(*b*) and Fig. (14) apply, $\psi = 90° - \theta$, and the resultant stress is parallel to the face of bridge, as it should be.

The writer has found by experience that the radial shear is negligible. It can easily be obtained, however, from Equations (51) and (52), since $V' = \varepsilon V$. The shear at any point in any radial plane is given by $V'' = V \sin \psi - V' \cos \psi$. The maximum or minimum radial shear is given by $V'' = \pm V \sec \theta'$, on a plane making an angle, $\psi = 90 + \theta'$. The writer has often been questioned in regard to these equations; they are given here for the sake of completeness.

MANUFACTURING CONCRETE OF UNIFORM QUALITY[1]

By William M. Hall,[2] M. Am. Soc. C. E.

With Discussion by Messrs. Henry B. Seaman, Theodore Belzner, John Sanford Peck, J. W. Kelly, Stanton Walker, Edward E. Bauer, O. Bonney and D. T. Mitchell, C. E. Arnold, Morris Mason, John H. Griffith, W. B. Wendt, and William M. Hall.

Synopsis

Most of the literature on monolithic concrete construction appears to be devoted to laboratory practice, the water-cement-ratio theory, and subjects relating thereto. Although the knowledge and technique thus obtained are essential for the construction engineer, they may not be as difficult to acquire, as it is to perfect the field methods of mixing and placing concrete of a desired uniform quality and strength.

In 1930, and a few years prior thereto, the United States Government completed, under direction of Lt. Col. George R. Spalding, U. S. A., nine locks and dams in the Ohio River between Louisville, Ky., and its mouth (nearly 400 miles). This task required more than 750 000 cu. yd. of concrete. In 1925, a systematic and uniform method of inspection and control of concrete manufacture was authorized, inaugurated for all the dams, and carried through to the end of the work. The purpose of this paper is to record the results obtained and to give a detailed description of the methods pursued with the hope of inspiring in others an ambition to adopt and perfect the practice of manufacturing concrete of a specified strength and grade with a reliability equal to that of the best of other structural materials.

With a realization of the importance of the perfect execution of all the inspection and of the co-operation of all the working forces in every detail of field work required in the manufacture and placing of concrete and

[2] Civ. and Cons. Engr., Parkersburg, W. Va.

in the fair sampling and making, curing, and breaking of cylinders, the writer has included in Appendices a detailed description of the methods followed by two field inspectors, Messrs. R. W. McBeth and C. F. Little.

The nine locks and movable dams are the last of a series of fifty built for the improvement of the Ohio River so that with slack-water there will be a minimum depth of 9 ft. on the lock-gate sills and the navigable pass sills of the dams. All the structures are now (1931) in operation at a total cost of construction to the United States of about $115 000 000.

INTRODUCTION

The requirement of first importance for any well-designed concrete structure is that the concrete be satisfactory as to: (1) Soundness; (2) density; and (3) uniform strength, approximately as designed, throughout every part of the structure. Although due regard should be given to the element of cost, every concrete structure should have a probable life as long as its intended use, or if that is unknown, for a period of more than 100 years, except in the parts which may be worn out by severe abrasion.

Although it is now nearly forty years since, in the early Nineties, the design and construction of monolithic concrete structures became active in the United States and Europe, more than 50% of the concrete being made is of poor quality. Its probable life is short and only a small part will comply with conditions for quality as proposed for it. Therefore, the question of how to eliminate the causes of such failures has long been of great importance. Of the three major qualities sought in its manufacture, uniform strength is usually the one of greatest concern; or, expressed otherwise, the improvement most desired is to design a mix of minimum required strength and, then, with confidence, to be able to guarantee every batch of it.

Although the choice of materials is of paramount importance, the personal element is a large factor in the manufacturing and testing of the concrete. Variations in quality may occur due to: (1) The method of procuring, inspecting, and delivering the materials; (2) the choice and installation of the mixer; (3) the arrangement of all the features of transportation from mixer to the finished concrete in the form; (4) the measurement of all the materials entering the mixer; (5) the method of charging; and (6) the sampling, making, seasoning, and breaking of test cylinders. Not only do the inspection and cylinder records indicate the relative durability and value of concrete, but so, also, does its appearance when being placed and when finished. When inspection records are favorable with regard to these features the engineer, architect, and owner may feel confident of the safety and durability of the structure, provided its placement is known to be well and thoroughly done.

It is with this thought and for these reasons that the writer is submitting some records of work done, methods pursued, and experience gained in an effort to produce concrete of uniform quality. No one or two easy remedies can be formulated or found, but the way to success, like that which has been required for all other good construction, will include the systematic training of the workmen who are entrusted with the principal details of concrete manufacture, placing, and treatment. Uniform success in producing good concrete requires reasonably suitable materials; and it also requires contractors, superintendents, and foremen with the spirit to co-operate; competent inspectors; and workmen with training, skill, and reliability for measuring quantities of water, cement, and aggregates, day after day, with unfailing accuracy. It is not intended to discuss theories of concrete design, laboratory practice, or specifications, except as they affect the inspector's work in the field. This task involves the selecting and inspecting of materials and the teaching and directing of the workmen as to their duties and faithful performance. By excellency of control he may be able to make the contractor and other managers of the work realize that such methods are for their best interest in producing concrete with a favorable record for quality, and that the net result will be economy in the cost of the finished work.

The greatest reason for much defective work is due to the owner's ignorance of its quality (or of how badly he has been duped), immediately after completion. Many engineers in highest authority have accepted a poor quality of concrete only to realize it years later. The appearance of the mix or an immediate test of the concrete, when freshly mixed or placed, does not disclose its quality with sufficient accuracy to separate the poor from the good, except that it indicates when excess water is present, that aggregate has segregated, or that the mix was greatly deficient in cement, sand, or water. Furthermore, the need of either accepting the concrete immediately or of condemning and destroying it has tended to permit the construction of much poor work. The cost of repairs or early renewals of defective concrete constructed in the United States to date (1931) will probably be in the tens of millions of dollars.

Although in the Nineties monolithic concrete construction was strongly condemned by engineers of high repute as an unreliable structural material, the great urgency for speed in the construction of fortifications in 1898, at the twenty-six strategic points encircling the coast line of the United States from Maine to Oregon, so broadcast the knowledge of its adaptability for rapid masonry construction that its use in all classes of bridge and industrial masonry was thereby hastened. Since then its use has been extended rapidly to include almost all classes of masonry. It was possibly the great extent of that fortification construction program and the concurrent demand for speed that saved it from general condemnation as a fit structural material and substitute for stone and brick masonry. The great pity is that in the decade following 1895, some super-power could not have controverted entirely the arguments advanced by advocates of excessively wet concrete mixtures and thus have avoided the introduction of long chutes which were so injurious, or ruinous, to good concrete. These two wrong methods of construction and a few others, which were much in use from 1900 to 1920, were apparently in danger of eliminating almost entirely the use of the better methods of mixing and placing which were very well known and strongly advocated by a few.

PRACTICE ON THE OHIO RIVER

Most papers and published records show an almost complete lack of uniformity in terms of maintained strength for job concrete up to or above that designed, even with aggregates of fairly uniform quality of grading and of water content. For many years on the construction of the Ohio River locks and dams, sand and gravel (usually with poor natural grading), were dug at the work and delivered at the mixer for immediate use. This practice made the control of the water content much more difficult than with stored aggregates. Many efforts were made to secure better concrete under such difficult conditions, especially in the past five years (1926-1931) during which more than 750 000 cu. yd. of monolithic concrete were placed in the nine locks and movable dams constructed in the Louisville District of the Ohio River. A brief statement of the methods used and the results obtained may contribute to a better understanding of the requirements necessary in organizing and conducting all the most essential details of mixing, placing, and testing concrete.

The concrete construction of Auxiliary Lock 41, at Louisville, Dam 47, near Evansville, Ind., Lock 51 and Dam 51, at Golconda, Ill., was done by contract, and the remainder by hired labor forces under the direction of a resident "Assistant in Charge", reporting directly to the District Engineer. The location and general description of these structures have been discussed by the writer in another paper.[3]

The Concrete Inspectors.—The inspectors assigned to mixing and placing, and the cylinder makers, were part of a force organized in 1925 for the field work of laying out and inspecting the work of construction of the locks and dams. Many members of the assembled force and nearly all the men at the mixers had previously had very little experience, instruction, or laboratory and field training in manufacturing or placing concrete. This accounts for the large number of failing cylinders shown in the report for 1925.

At the beginning of the work, all the members of the concrete inspection force were required to study a digest of the literature on the subject, including the theory of Duff A. Abrams, M. Am. Soc. C. E., on the water-cement ratio, his proposed methods of determining fineness modulus for aggregates, and other methods of control. A system of making and testing concrete cylinders was also begun in August, 1925, A short time afterward the inspection forces, with some of the principal members of the construction force, were organized as a school. Its first meeting of a week, with two sessions daily, was held in January, 1926, at Dam 52, Brookport, Ill., the next two meetings were held at Owensboro, Ky., and the fourth was held in Louisville, in February, 1928. Under a leader, the inspectors were required to study at their respective stations, the specifications for the job, the specifications of the American Society for Testing Materials, and the several bulletins[4] and booklets[5] formulated by Professor Abrams. Then they attended classes, as stated previously, conducted by the writer, with J. W. Kelly, Assoc. M. Am. Soc. C. E. (through the courtesy of the Portland Cement Association) as principal teacher. Papers were also prepared, read, and discussed by members of the inspection force on questions relating to the plant, their own difficulties, and construction features at the various locks and dams. Copies of some of the complete papers, and carefully prepared minutes of all sessions, were later furnished to the entire force. Under the Abrams' standard for average strength of cement,[6] the specifications for the job should produce a concrete made with the average Ohio River gravel, with a compressive strength of about 1 700 lb. per sq. in. at 28 days. The job standard of minimum strength was set at 2 000 lb. per sq. in. for 28-day concrete, and 2 800 lb. per sq. in. at 6 months which is a high standard for the specified proportion of cement to aggregate.

[5] Pub. by the American Portland Cement Assoc.

During 1925, 1926, and 1927, only one cylinder was made from each sample or batch of concrete. In 1928 and 1929, the cylinders were made in pairs, two cylinders from each sample or batch tested. In this manner one cylinder of the pair checked the fabrication of the other. If one cylinder failed in proposed strength, or if the tests showed a great difference in strengths, it was believed that the higher record could be assumed to be the true measure of quality of the entire batch from which the sample was taken. Throughout the seasons of 1925 to 1928, inclusive, the cylinders were packed in sand, two in a box, and shipped to a laboratory at Louisville. During 1929, the cylinders were broken under contract at the Testing Laboratory of the University of Louisville. The agreement included the care of the cylinders during the last days of seasoning, and re-capping them when the ends were not perfect. The record for 1929 included every cylinder made. For the other years only about half a dozen cylinders were rejected due to injury or other cause that clearly made the break recorded an unfair test. Table 1 indicates the strength of the concrete. Of the thirty-eight cylinders (nineteen pairs) made at Auxiliary Lock 41, Louisville, which were tested at the age of six months (see Column (12), Table 1), four (each cylinder of two of the pairs) were subjected to 200 000 lb. (7 100 lb. per sq. in.) and failed to break. This was the limit of compression for the testing machine available. One month later, one of these cylinders broke, in the same machine, under a total pressure of 194 000 lb., and its mate at 182 820 lb., or 6 450 lb. per sq. in.

SPECIFICATIONS

The specifications for the work provided that the concrete should be composed of cement, hydrated lime, sand, gravel, and water. The cement measure was by count of bags for each batch. The aggregates were measured by leveling up to exact marks set in the charging hoppers or by batchers and inundators. The water was measured by gauges in barrels or by water meters. The sand, gravel, and water were taken from the Ohio River, under specifications requiring the best that could be produced in the locality of the structure. The mix per cubic yard of concrete consisted of 5 bags of cement

---

[6] *Bulletin 1*, "Design of Concrete Mixtures," by Duff A. Abrams, Lewis Inst., Structural Materials Research Laboratory, Chicago, Ill.

(6 bags for all reinforced concrete and tops of walls), 25 lb. of hydrated lime, or other equally good admixture, and 25 cu. ft. of gravel. Sand was required sufficient to yield 15% or more of mortar than was needed to fill the voids in the gravel and sufficient water to produce a slump of 2 to 4 in. for mass concrete and 5 to 6 in. for reinforced concrete; that is, such that the feet would not sink in freshly spread concrete deeper than 10 in., nor less than 2 in.

TABLE 1.—Cylinder Tests of Concrete in Dams on the Ohio River Improvement

It is believed that the workmen complied with these specifications in general, except for the batches that fell below the desired strength, or those below the proposed strength (see Items 6 and 7, Table 1). In these cases there was probably either some defect in complying with the specifications or in the making, handling, or breaking of cylinders that were defective. It was the rule to keep a complete record of every detail which might affect the strength of every cylinder from the time the sample was taken to the time the cylinder was broken. Even so, in the case of more than 50% of failures to exceed the proposed strength, it was impossible to find an adequate explanation of the cause. The observable cause of greatest frequency was the segregation of large-sized gravel which produced evident weakness because the mortar peeled off and left a clean, bright surface of stone. Another frequent condition observed was a lengthwise split in the cylinder, indicating an imperfect bearing on the end. In 1929, this defect was eliminated by greater care in detecting and re-capping slightly defective ends.

INSPECTION

The cost of maintaining any desired minimum strength will probably not be any more than that of concrete which actually fluctuated much above and below such standard of strength. Uniform maintenance certainly requires a knowledge of concrete materials and of manufacture on the part of all concerned and also a systematic and constant control, as may be better understood from Table 1 and a few comments based on the instructions given the inspection force from time to time.

Advance Study.—Before being placed on duty, inspectors were instructed and helped to become thoroughly familiar with the specifications, the tests relating thereto, and the methods of making them. Furthermore, they were taught the duties involved in the direction and instruction of workmen. They were also instructed in the technique of obtaining samples of materials and of analyzing the different grades of sand and coarse aggregates available.

Laboratory Experience.—For a better understanding of the literature studied, each inspector analyzed the sand and gravel being used. He mixed concrete by hand and made experimental cylinders from them, recording his results and reporting them in writing to his Senior Inspector. For each of the proposed slumps (approximately 2, 3, 4, 5, and 6 in. with the materials furnished and accepted for concrete on the particular job assigned), the inspector determined the water-cement ratio and kept a record of it. Aggregates were analyzed and, if the particular job received several distinct grades of aggregates, tests were made of each. As soon as possible after construction was in progress, the inspector plotted "typical job curves" of 28-day cylinders, indicating the water-cement ratio on each curve. Copies of such data were promptly forwarded to the office for review.

Practical Field Inspection.—The greatest possible care was required of inspectors in the field to obtain exact measurements of materials for each batch of concrete. The quantity of aggregates required by specification was their measure, "dry and rodded". Because the bulking of gravel is so slight and so nearly constant, its measure was considered exact or, at least, correct within 1 per cent. The measure of sand was variable because the gravel carried sand, and when an inundator was not used, the bulking was irregular. As nearly as possible, the measure of water was maintained so as to give a 3-in. slump, except that a 4 to 5-in. slump was required in case of concrete used with reinforcement and where it was difficult to place dry concrete. To maintain this slump uniformly every mixer inspector needed to understand the principles of the water-cement-ratio theory, the best and quickest methods of keeping informed as to measures of materials, quantity of water in aggregates, and method of correcting error in slump by changing the measure of water or sand, or cement in an emergency, and all things relating thereto at his plant. The slump and workability are functions of all the foregoing variables, and the importance of maintaining their uniformity was impressed on the inspectors. Before starting a monolith and at all times when the mixer was in operation the inspectors were expected to have perfect arrangements made for quick communication and co-operation, and for instant action.

As early as practicable, and before beginning the concrete mixing, the inspectors became thoroughly familiar with the operation of the mixing plant and with the personnel assigned to it; and they satisfied themselves that every one assigned to a particular task could perform his duties accurately and efficiently. Furthermore, they inspected the form to see that it was completely finished with a well prepared foundation bed properly unwatered. If it was a connection with old concrete, they looked for laitance, and directed its thorough removal. The old surface, thus prepared, was completely covered with a thick layer of mortar or grout.

The regulation of the quantities of materials and of the time of turning the mixer for each batch of concrete are the mixer inspector's most important duties. When the mixer is in operation he should remain on duty until relieved by another inspector. Dumping or chuting concrete into forms should be done so as to require spreading only, or a short movement, at most, not exceeding 10 ft. Great care should be taken to prevent any part of the concrete from striking the forms, the forming rods, or the bracing timbers. These items were emphasized in the instructions issued to inspectors.

The greatest care possible was taken to obtain fair samples for slump tests, and those for cylinders were preferably taken from a 5-bag mix. The inspector was instructed to indicate on the records whether lime or an extra half bag of cement was used, or whether any other variation or irregularity occurred. The age, make, and bin number of cement, and the seasoning temperature of cylinders and the maker's name, were also required.

Regarding slump tests, the instructions specified that: Samples of concrete for slump tests shall be taken within 10 min. of its discharge from the mixer. When starting concrete work, the slump test shall be made from the first batches mixed, and continued until a 3-in. slump is obtained and is running uniform; thereafter, while mixing is in progress, it shall be made at intervals of 1 hour, or oftener in case the consistency appears to change. Samples for cylinders shall be taken from forms immediately after being dumped and within 10 min. of discharge from mixer. A chart similar to progress drawings shall be kept, indicating (1) the location of each concrete monolith; (2) the cylinder batches in each monolith by serial number; and (3) its approximate location in the monolith.

Instructions as to Removal of Forms.—No forms were permitted to be removed in less than the time stated in the specifications without actual physical inspection by an assistant in charge to determine the set of the concrete and without concurrence by the senior inspector. During summer weather it was considered entirely safe to remove bulkhead forms after 24 hours from lifts of approximately 6 ft.

During the summer, the inspectors were permitted to allow a few men to walk on the concrete for the purpose of brushing after about 6 hours, but no succeeding lifts of concrete could be cast above one lift for a period of 48 hours.

Especial attention to the curing of concrete was required, and inspectors were instructed to follow in detail the specifications as to time of keeping forms on monoliths and of keeping surfaces wet.

Test Cylinders.—As every minute detail of the processes of sampling, transporting, making, curing, and breaking cylinders affects the record of breaking strength, the detailed account of the process, as described by Mr. Clifford F. Little, the Inspector who made all the cylinders at Auxiliary Lock 41 in 1929, is given in Appendix I. The standard cylinder, 6 in. in diameter and 12 in. high, was used for that and all other cylinders to which reference is made in this paper.

All the methods used were intended to be as prescribed by the Standard Specifications of the American Society for Testing Materials (Serial Designation, D 138-26, T), but, for obtaining uniformity, a detailed explanation or description of every movement was found desirable.

Due to defective bottoms, the entire first lot of moulds, purchased in 1925, was discarded. The second lot, purchased in 1926, from another maker, gave some trouble of the same kind, which is believed to account for some of the defective cylinder records from 1925 to 1928, inclusive.

A glimpse of the work and some further idea of its character may be obtained from Fig. 1. It shows the lower face of a part of the upper gate miter wall, a little of the finished face of the upper end of the right chamber wall, and the concrete forms erected for the head-house which includes the operating machinery of the upper filling valve. The masonry up stream from the gates is the wall of the old lock with its new concrete top which converted that lock into an upper guide-wall for the new lock. Fig. 2 shows the appearance of more of the face of the right chamber wall just after the forms and before the tie-rods were removed.

The specification for concrete in Auxiliary Lock 41 provided for about 24 cu. ft. of gravel instead of 25 cu. ft.; acting at his own suggestion and without change of specification or price, the contractor furnished double-ground cement instead of the standard required under the specifications. A comparison of the relative strengths of the 28-day cylinders and the cement with which they were mixed in 1929 (and some in 1928) and the relative strengths of the cements used in the corresponding years indicated clearly that the cement is usually the factor of first importance. Of course, it should always be realized that with good cement other errors may ruin the concrete.

In 1928, a particularly bad lot of cylinders was tested in a series made at one dam despite the constant vigilance maintained to prevent such errors. They were made and cured by a trained engineer, but due to other duties, he entrusted, to an experienced laborer, the task of transferring them from the seasoning bin to the place at which they were packed for shipment to the testing laboratory. Although the laborer had been around the laboratory and the

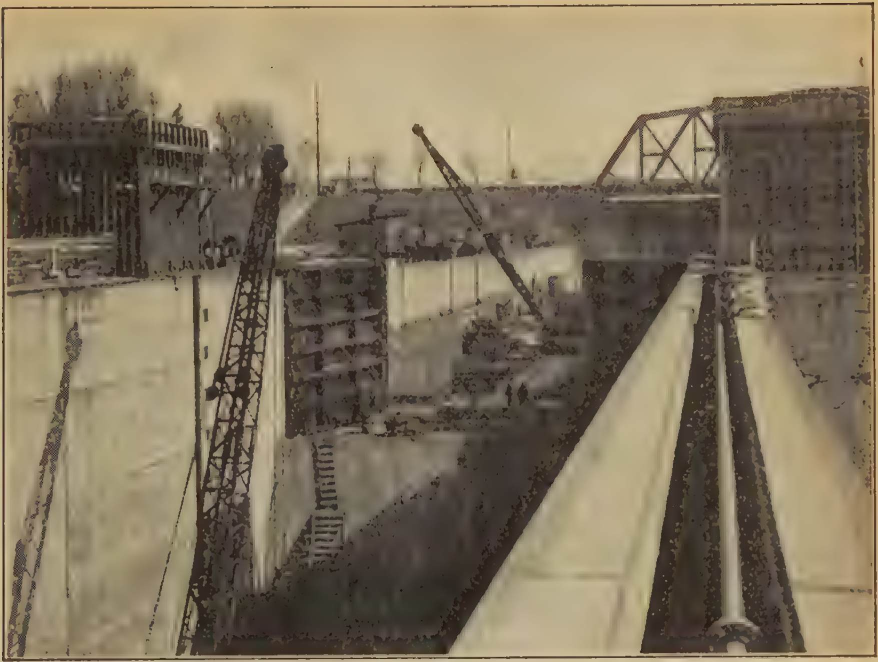

FIG. 1.—VIEW OF CHAMBER WALL JUST AFTER REMOVING FORMS, AUXILIARY LOCK 41, LOUISVILLE, KY.

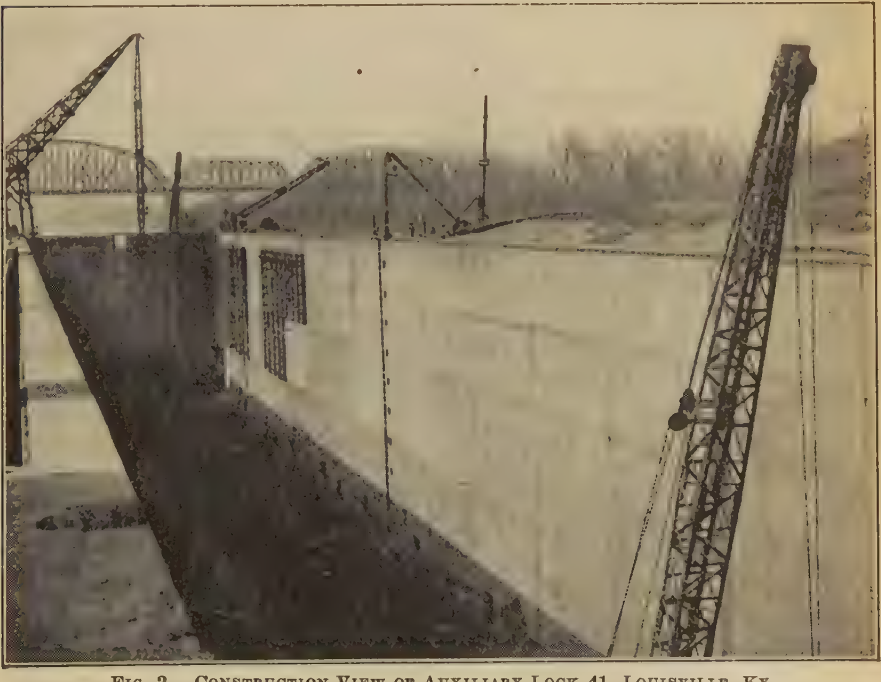

FIG. 2.—CONSTRUCTION VIEW OF AUXILIARY LOCK 41, LOUISVILLE, KY.

work for months, he had failed to absorb the essential character, the purpose or importance of the cylinders, and after moving one to two dozen he was discovered with a pair in a sack giving them only a little better treatment than is customary with dull picks going to a shop.

Irregularities in the Strength of Concrete.—The principal causes of the great variations that occur in job concrete (as indicated by cylinder tests made on this work during four years) are the corresponding variations in:

(*a*) Strengths of cements of different brands, from different bins and from different parts of the same bin;
(*b*) Water content of aggregates, resulting in variations in water content of the batches;
(*c*) Correct measurement of aggregates (especially of sand), the water, and count of bags of cement for each batch (and the resulting water-cement ratio);
(*d*) The grading of aggregates;
(*e*) The cleanness of the aggregates and the quality of the water;
(*f*) The time of mixing the concrete; and
(*g*) The sampling, fabrication, curing, curing temperature, handling, or breaking of the cylinders.

It is evident that these variations may be grouped into two principal classes: (1) The variations in the natural materials from which the cements are manufactured, in the natural grading of aggregates and content of silt and other foreign matter, and in the quality of the water as found in the river or other source; and (2), the variation in men, the competency and care exercised by the men performing all the many duties required in the entire process of preparing and assembling materials, transporting, mixing, and placing the concrete, and also by the opinions and attitude of those in supreme authority relating thereto. Lack of knowledge or failure to detect and regulate irregularities in one or all the foregoing seven conditions is responsible for the nearly universal failure of engineers in their effort to specify, manufacture, and place concrete as good as any specified quality.

When materials of reasonably uniform quality are provided, the writer believes that men can now be so well trained as to manufacture concrete (using laboratory methods) with the same certainty of producing a uniform product as a bread-maker can, for example; and on the job, with great irregularities in materials, such uniformity as is indicated in Table 1 should be obtained. After such uniformity is obtained and the lowest record in 50 or 100 cylinders is above the designed strength, then and only then should an economy be effected by reducing the proportion of cement or otherwise. When such reductions are contemplated, the inspector should be sure to maintain the designed standard.

Cement.—An account in some detail of the field methods used and results obtained in the construction and management in assembling materials may be useful for reference and comparison. All cement for the Ohio River improvement was purchased under specifications and contract, and was sampled and tested by professional laboratories. Samples were taken from every bin of cement and reports were made as to chemical tests, physical tests for fineness, time of setting, and tensile strength of 7 and 28-day briquettes.

Table 2 is an abstract of the cement test reports for 1928 and 1929 at various dams as noted.

Curves were plotted showing fineness and strength tests for 7 and 28-day briquettes. Due to the difficulty of storing and tracing shipments the bin number of the cement in each cylinder was not kept, except for the year 1929. Variation in fineness and in strength between the different kinds of the same cement as well as differences in brands, are more readily and clearly understood by plotting them as curves than by the tabulations of figures from which the curves are made. The variations in fineness in 1927 and 1928 are probably greater than is realized by those not accustomed to make such plottings.

TABLE 2.—CEMENT TESTS, 1928 AND 1929, GIVING AVERAGE TENSILE STRENGTH FOR 7 AND 28-DAY BRIQUETTES AND FINENESS MODULUS FOR EACH BIN OF EACH CEMENT USED

In 1927 the 7-day briquettes of all brands used, varied in tensile strength from 241 to 345 lb. per sq. in.; and for 28-day briquettes of all brands used, the variation was from 326 to 455 lb. per sq. in. In 1928, the variation in tensile strength for 7-day briquettes was (see Table 2) from 238 to 405 lb. per sq. in. and for 28-day briquettes, from 309 to 459 lb. per sq. in. In 1929, for 7-day briquettes of Cement F only, the strengths varied from 253 to 405 lb. per sq. in., and for 28-day briquettes (see Table 2), the variation was from 388 to 500 lb. per sq. in.

In addition to the contract tests, complete field tests of cement that had been kept over winter were made according to the Ohio River General Specifications. Furthermore, two samples were taken from each car of cement as received at the work, one from each end of the car, and tested for soundness after the method specified[7] by the American Society for Testing Materials before being used. The use of cement stored over winter almost invariably resulted in low-strength concrete even when one or two additional bags of cement per cubic yard of concrete were used. This fact is painfully accentuated by the plottings in Fig. 3.

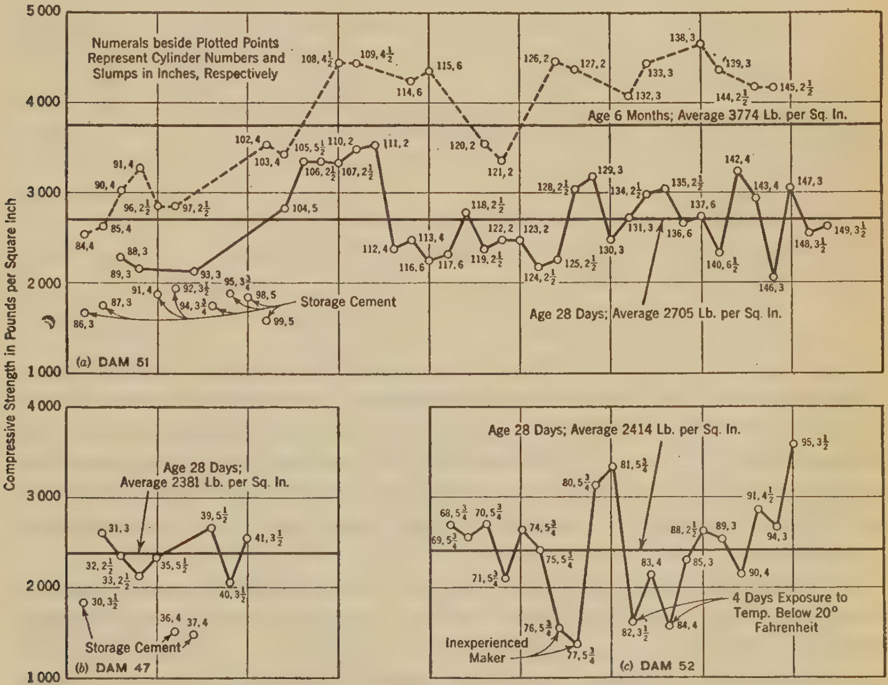

FIG. 3.—CYLINDER COMPRESSION TESTS OF CONCRETE IN LOCKS AND DAMS, OHIO RIVER IMPROVEMENT.

Table 2 indicates the great variation in the brands of cement used from year to year and also the variations in the samples taken from the same brand during the season of several months. All these tests were made at the highest class of professional laboratories and they show similar variations throughout all the reports.

---

[7] Standard Specifications, 1924.

In cases of carefully fabricated briquettes of cement and of cylinders of concrete made of cement from the same bin, although the two strengths do not uniformly correspond, it is not believed that all the variation is due to the cement. Frequently it is due to numerous causes, such as irregularities in water content, grading of aggregates, and other irregularities described elsewhere in this paper. However, the variation in cement probably causes the most frequent and the greatest variations in the strength of the concrete where there is reasonably competent supervision. With incompetent or careless supervision the variation in water content is, no doubt, the condition which causes the greatest variation in strength and which is probably causing more concrete to fall below the proposed strength than all other conditions combined.

Aggregates.—Table 3 gives the average of several samples of the aggregates (Ohio River sand and gravel) used at each dam with which the concrete, shown in Table 2, was made. Table 4 presents characteristic sieve analyses for the aggregate used at eight of the tests. The specifications stipulated that, "gravel or broken stone shall range in size such that at least 95 per cent. will pass through a 3-inch diameter ring, and not more than 15 per cent. will pass a No. 4 sieve".

When the aggregates are taken from the bars of the river, as was done on these works, their grading to a much greater refinement than about as indicated in this specification is not believed to be worth the cost in improved quality thereby obtained. However, there is no question that every barge load should be drained sufficiently to prevent change in the water-cement ratio. When inundators were used for measuring sand the rule was for 6 hours or more of drainage of gravel to prevent excess water in the mix. Gravel long submerged in back-water was re-washed. Such gravel by test was found to reduce the strength greatly.

Tools for Placing.—When placing concrete it is most important to have a sufficient number of men in the form at all times, and that each man should be trained for his duties. They should know especially how to dump buckets and chutes, and how to spread concrete without causing it to segregate. Each spader assigned to a particular part of the face should be made responsible for that section and should be made to understand that the central mass must be thoroughly spaded and trampled to release entrapped air. The foreman should understand how to remove excess water and how to solve all other field problems affecting the quality and appearance of the finished work. There should be plenty of tools in good order for men on duty and some extras. The principal tools required on the Ohio River improvement were D-handle shovels, D-handle and long-handle spades, long wood spades, with blades about 4 by 10 in., and (for use in thin walls) bars and light hammers. A carpenter was stationed to work in the forms during the time that concrete was being placed.

Mixers.—All the mixers were of the "batch type machine" required to produce concrete of uniform consistency and workability. The mixing was continued for not less than 2 min. for a 2-yd. mixer, 1¾ min. for a 1½-yd. mixer, and 1½ min. for a 1-yd., or smaller, mixer, after completely charging and before beginning to dump. The batch was dumped into buckets on cars, lifted from the cars by derrick, and dumped (usually from bottom-door buckets), direct into place or into a hopper at the top of the form. From the hopper it was then conducted into place by a hose chute from 8 ft. to a maximum of about 25 ft. long, great precaution being required in all movements to reduce the segregation to the least possible. At the end of the specified mixing period for any batch, in case the dump bucket had not arrived and been made ready for receiving the charge, the mixing was continued until the bucket was ready, thereby improving the concrete, but introducing another factor for irregularity in strength.

The mixer for Lock 41 was of 2-yd. capacity, that for Lock and Dam 52 of 1¼-yd. capacity, and all the others were of 1 and 1½-yd. capacities.

Some instructions were given the foremen and men operating the mixers, but usually this was not begun early enough. The lack of trained and dependable men was a frequent cause of defect, which should be remedied by selecting the highest class of men procurable for experience and intelligence, and well known for integrity and reliability. Men who think the water-cement ratio useless, or that wet concrete is "good enough", should not be employed. They are especially objectionable in any position of authority. The crew on the concrete mixer and batch-placing forces in the forms should be selected with the greatest care as to experience and reliability some days in advance of commencing the work. Ordinarily, with competent inspectors, the direction of the principal men who are assigned to measure the materials, and the men in the forms, spreading, spading, and finishing the concrete, do most thorough work when under the direction of the inspector. The form inspector's proper position is close enough to the men to speak with ease to any one.

Throughout the season of 1928 Inspector R. W. McBeth had charge of the inspection of concrete materials, the mixing and placing of the concrete at Dam 51 and, during the season of 1929, he had similar duties at Auxiliary Lock 41. His recommendations for the proper inspection of concrete construction is described in Appendix II.

Conclusion

It is most fortunate for the artisan who can turn concrete mixing and the fabrication of cylinders into a game, or even more fortunate when he can, also, convert it into an art based upon highly scientific knowledge verified by laboratory experiments, as was done by Professor Abrams.

When the people who are paying for the concrete production of this country realize sufficiently the value of such skill, art, and knowledge as to demand uniform quality for soundness and a fixed minimum for strength, it is probable that the class of training indicated in this paper will be so perfected and extended as to make uniform products in concrete as usual as in other materials of construction.

The writer wishes to express here his appreciation of the great assistance of his associates with whom he has had much pleasure in accomplishing the tasks incidental to this class of work during many years.

APPENDIX I

Making and Seasoning Concrete Test Cylinders in the Field

By Clifford F. Little,[8] Esq.

The method given herein has been applied in moulding and seasoning test cylinders made from specimens of the concrete used in the construction of Auxiliary Lock 41. The process may be described in steps as follows:

(1).—Collecting the Sample.—After the first batch of concrete has been dumped the inspector hands two pails to one of the laborers in the form, giving him directions to fill them. The sample is promptly carried to the laboratory.

(2).—Making a Slump Test.—Upon arriving at the laboratory it is dumped from the pails to the dampened concrete floor and then immediately turned over by eight strokes of a large trowel. This operation will rectify any segregation which may have occurred in transportation and by dumping the sample from the bucket. Immediately thereafter, its slump is tested by filling the slump cone with three, 4-in. layers, puddling each layer with twenty-five strokes of a bullet-pointed $\frac{5}{8}$-in. rod of standard design. After the last layer has been puddled, the surplus concrete is struck from the top of the cone with the rod. Then, by use of the handles, the cone is slowly raised vertically until it clears the top of the concrete, and is placed beside the specimen. The rod is laid horizontally across the top of the cone, and, in that position, its distance above the top of the specimen is recorded, in inches, as the slump of the concrete.

(3).—Preparing the Cylinder Moulds.—The moulds are prepared for concrete before the sample is brought from the form. Every particle of old concrete is removed and then the inner surface is rubbed with a light oil. This treatment reduces the tendency of the new concrete to stick to the mould. Bottom plates of the brass and of the heavy cast-iron moulds were found unsatisfactory on the Ohio River work and they were replaced by steel plates 8 in. square by $\frac{1}{2}$ in. thick, machined to a true plane on one side. These plates produced very satisfactory results in securing true ends to the cylinders so that they rarely required re-capping.

(4).—Making the Test Cylinder.—Care should be exercised when placing the mould on the bottom plate to see that no small particles of sand have been caught between the bearing surfaces of the plate and the mould. After making these precautions, spread the concrete which was used to make the slump over the remaining concrete of the sample. Proceed immediately to make the cylinder by placing concrete from this sample in the mould in three, 4-in. layers, puddling each layer with twenty-five strokes of the $\frac{5}{8}$-in. rod. Care should be exercised to remove all pieces of aggregate that are more than 1 in. in diameter. After puddling the last layer, press down the top concrete in the mould with the blade of the large trowel thus removing all excess con-

---

[8] Insp., U. S. Engr. Office, Louisville, Ky.

crete and any air-pockets left by the rod. When all the excess concrete has been struck off with the trowel, give the top end a final finish by rubbing the rod over it.

(*5*).—*Capping and Storing the Cylinder.*—After the cylinder is made, prepare a stiff, neat paste for capping, with cement from the same bin as that used in making the cylinders. Soon after the cylinders and paste have shown the final set (by needle), the paste is re-worked until it is soft, and then it is spread on top of the cylinders in a thin layer, about $\frac{1}{16}$ in. higher at the center than on the edges. A sheet of thin oiled paper is spread over the top and one of the steel plates is placed over this paper. The plate is then pressed down and slightly turned from one side to the other until it has a firm bearing on the entire edge of the mould.

Thereafter, the cylinder is not disturbed for 24 hours. At the end of this period remove the moulds carefully, wipe all loose particles of sand from the cylinder, and place it on end on a perfectly plane surface. Place one hand on top of the cylinder and rock it slightly in all directions. Should the end be imperfect, a tilting motion of the cylinder will be felt, indicating that the end is not a perfect plane. It may be made perfect by rubbing it over the plane surface of the steel plate until no rocking motion can be detected by observation or by "feel".

The ends should also be tested to see that they are perfectly parallel. This may be done with a carpenter's square or by placing the cylinder in the testing machine. If they are not perfectly parallel, they should be made so by rubbing or by re-capping. After both ends of the cylinder have been treated in this manner, so that they will coincide perfectly with the plane surface of the testing-machine bearing-plates, they are marked and stored in damp sand which is kept within 15° of the average temperature of 75° Fahr. They are not again disturbed until the shipping date, when they are re-packed in shipping boxes filled with sand and shipped by truck to the testing laboratory. There, again, they are transferred into sand storage of about the same temperature as that in the field laboratory until they are broken in the testing machine.

APPENDIX II

Inspection of Concrete Construction

By R. W. McBeth,[9] Esq.

Hostility is one of the greatest obstacles to the control and inspection of concrete construction. Frequently, construction heads refuse to be informed, or to attend school. Indifference and hostility prevent the spreading of proper information and the co-ordination of operations between these workmen and the inspectors.

---

[9] Insp., U. S. Engr. Office, Paducah, Ky.

Plant Location.—The plant should be so installed as to get maximum output and this requires that every detail must be studied, and the installation made with care. Mixer frames must be secured firmly to solid foundations, and made plumb and level. Bearings and clutches, especially the tilting gear-clutches, need the closest attention. The charging hoppers should be set as close to the drums as clearance will allow. The throat of the hopper should be enlarged to the limits that the feed-opening of the drum will permit, and the tilting transfer scoop should be correspondingly enlarged, to prevent choking and spilling.

Mixing Water.—Water tanks should be cylindrical and set vertically, as nearly as possible over the drum feed, and the discharge pipe should be carried directly from the tank to the top of the drum feed-opening, without abrupt angles or bends. It should end in a flattened nozzle situated so as to deliver the mixing water on the rear third of the drum. This will give a quick, clean delivery of water. The tanks should be calibrated and fitted with gauges and floats automatically reading to gallons. The gauge marker should work accurately and smoothly.

Batch Mixing.—The inundator operator should be carefully trained by one familiar with its mechanism and "kinks" of operation. The use of a separate cement charging hopper is of much value because it eliminates hopper fouling. A common fault of concrete plants is a slow rate of feed to the drum. Many charging hoppers require 40 sec., whereas it should be done in less than 25 sec. A batchmeter should be installed on the mixer, so that the inspector will have a chance to watch the mix. Stairs and ladders should be placed so as to afford quick and easy access to all parts of the plant. The interior of the mixer drum should be brightly illuminated, day and night. When the hopper gate is open a spotlight may be thrown diagonally down the hopper into the drum. In non-tilt mixers, this is the only practical method. If bag cement is used the best method of charging is to empty bags into a skip that dumps at the top of the hopper, clearing the stream of mixing water. The skip should be as long as possible to minimize the splashing of cement. A locking and recording batchmeter should be a part of the plant equipment.

There are many things to be done beside checking tally and ringing bells, and the tallying is certain to be inaccurate when supervision and operation constantly interfere with timing and checking. The water tank should be covered and the valves and piping should be kept in good order. The platforms for observing changes in the mix and consistency and for workmen should be well lighted. When mixing is suspended for an hour or more, the mixer drum, and all the platforms, the hoppers, or chutes, at the mixer and in the form, should be thoroughly cleaned.

Many samples of sand and coarse aggregate should be carefully selected so as to represent the extremes of materials proposed for use. When separated into their respective sieve sizes they exhibit the grading. Weights of both materials per cubic foot in "dry rodded", "dry loose", and "damp loose" states, must be ascertained; and, also, the bulking of the sand with the probable moisture range. Piled in barges, stock piles, and plant bins, the aggregate naturally separates into coarse and fine particles and it is useful to know the effect of the different sizes of materials in a mix.

In general, a batch of coarse material, following a run of fine, is likely to produce a coarse, wet mix, which can be placed with comparative ease, but which results in poor construction. Fine material, on the other hand, will produce a wet mix with wet gravel, or a dry mix if the gravel is dry or low in moisture content. This is due to the much greater surface area, which takes up water from the mix if it is low in moisture, but adds water if it is wet. In either case, a run of fine gravel in a batch will cause a harsh mix, difficult to place, but one that produces good concrete if well compacted in place. However, it is usually difficult to get this tamping done properly.

To obtain good work, special care is required when the grading of sand or gravel is frequently changing. The specified measure of sand (equal to voids in gravel plus 15% of voids) will ordinarily give only a sufficient amount when a workable mass is well mixed; and, therefore, care must be used in making allowances for bulking. Sand thus proportioned should cover the maximum of voids likely to occur. Weighing batchers are preferable for obtaining accuracy in measuring coarse aggregate.

The mix should be watched and if the concrete is harsh, more sand is desirable. A slight reduction could be made in the gravel charge, but not quite enough to balance the increase of sand. Ordinary changes of ½ cu. ft. for fine or coarse aggregate will not unbalance the yield. Due care should be taken to see that the gravel "batcher" is set accurately. Variations in this unit will change the relative proportions twice as fast as the sand batcher, for a desired change of proportions in the charge.

A good method of determining proportions to be used at the beginning is the "trial method" devised by F. R. McMillan, M. Am. Soc. C. E., and recommended as standard by the Portland Cement Association. By this method, the mix is made in small batches to determine the correct point of workability with several water ratios. Coarse and fine gravel is analyzed in the various proportions and water-cement ratios. Various mixes are studied until the inspector is satisfied, and then the quantities required are determined for the batches so as to duplicate the best trial mix, in the actual structure.

Inspection During Operations.—When the plant has started, the slump test should be made of each batch until they are satisfactory. The batch should be observed carefully at the mixer, in the bucket, and when it is being placed in the form. The inspector should note how it acts, and should not hesitate to ask the foreman and form inspector, or the placing gang, how it behaves. He should spade and tramp it himself. In making the slump on trial a well-balanced mix should not slump off on the side and show gravel, provided the cone is lifted smoothly and steadily. Such a tendency indicates insufficient mixing or insufficient sand. By remembering that 4.7 lb. of cement is 0.01 of a 5-sack batch (1 cu. yd. as specified) and knowing the weight of all other materials per cubic foot in all conditions, computations required for changes are made easier. The material bins should have slopes of not less than 50° to the batcher gates. The grading of aggregates may be improved or injured by methods of loading and unloading.

The location of material supply piles and plant machinery is very important to efficient operation. For a river coffer-dam both should be situated so as to protect supply barges from the current, allowing easy handling for turning and cleaning off the barge. The relative position of barges, derrick, and mixer must be such that a minimum of movement is required to place material in the bins. By care in this operation the grading of gravel may be improved, or, by lack of care, it will be injured. To have a good signal man who understands this process of improving grading, is very advantageous. The bin should be in view of the derrick operator, and his operating house should be set so that he has a clear view of the plant and barge.

Concrete forms should be wire-brushed and oiled every time they are stripped. They should be kept wet so that cracks do not open up and the panels warp. This may cause complaint, but it is worth while, especially in close forms, and where finish is desired. Where reinforcing steel is used, the forms must be oiled before the steel is placed. Mortar should be placed in the bottoms of all lifts for bond; it is difficult to obtain neat cement, when so used, in sufficient quantity. Mortar will help correct any effect of dry batches when starting a monolith. Lack of control at the mixer may result in occasional dry or wet batches in the form, especially at the start, should the moisture content of the aggregates change quickly.

Plant Control Equipment.—The inspector or control man should have a laboratory on the charging floor, with a high-grade laboratory scale of large capacity. It should have a triple beam, graduated in decimals, a 5 000-gramme torsion balance measuring to ½ gramme, with special platform and a one-point suspension unit for specific gravity determinations. A 6-in. cylinder with a capacity of 0.2 cu. ft., fitted with double weirs and "strike off" cover, is useful. The following should also be on the list: A 1-cu. ft., bored steel measure; a 0.1-cu. ft. measure with scoops and rods; two slump cones; scale and balance scoop pans with counterweights; buckets and plenty of pans, large and small; an oven taking the largest pans, if practicable, with an electric heating unit of 1 800 watts and with three or four-point control; two 50-cu. cm., and three 150-cu. cm., cylindrical graduates; a pycnometer; a dozen mason jars; a dozen 8-oz. graduated prescription bottles, with corks; and a 1-gal. jug, with a cork. A full set of standard sieve analysis screens, with pan and cover, 12 in. in diameter; two steel shaker-frames, one for sand and one for coarse aggregate sieve nests, with electric vibrator for shaking samples of aggregates, are essential. Brooms and heavy dust brushes, a sink and large floor pan housed in a well-lighted and practically dust-proof room on the platform—all of these items comprise the essential equipment needed for plant control.

If thorough preliminary examinations have been made, the control man will have most of the necessary reference data and charts at hand; otherwise, he will have to develop them in the course of his control work. If the scales and balances are as specified herein, no conversion tables will be needed, and the work will be simplified and expedited. At any time the control man can catch a sample of either aggregate from the batch as it falls, and from it, in a few minutes, he can have any data desired.

All the apparatus mentioned is designed for rapid and accurate work, and, with some practice, two or more determinations can be made almost simultaneously, enabling the inspector to keep close check on all characteristics of the materials in use, and quickly to detect any changes.

With weight-batching, the proportions can be changed completely between batches if necessary, to meet any material changes in grading. The control man should be chosen not only for his knowledge, but for a deep interest in the work, and a known desire to produce the best possible concrete at the lowest possible cost. Such a man will have an enjoyable job. He should be in charge of the plant, including the batchmeter and the repair work. With such equipment, the inspector may be able to obtain satisfactory results unless by chance some one has omitted from the contract specifications one or two essential paragraphs.

The control of concrete is a great game and when one can look at thousands of yards of good concrete in a big structure, with few defects, he will feel that it was well worth the effort.

DISCUSSION

Henry B. Seaman,[10] M. Am. Soc. C. E. (by letter).—With uniform materials and uniform methods of manufacture, such as those described by the author, one should obtain reasonably uniform results; a variation of 20 to 50%, as shown in Table 2, would seem to be as uniform as may be expected. In the construction of bridge masonry in large mass, however, more than uniformity is desired; solidity and durability of the structure are also necessary. Early strength may be misleading. It has not been considered a prelude to durability. Engineers have preferred a cement that is moderately slow-setting, with gradual and continuous increase of strength. Care must be taken not to "drown" the cement and produce laitance, but a moderately wet concrete has been found to give the most satisfactory results.

The importance of thorough mixing is as great as the quality and quantity of cement used, or of the water-cement ratio—whether it be 5½ or 6½ gal. of water per bag of cement—and usually much less than that will suffice. Then, too, a proper and complete distribution of aggregates in the forms is important.

Concrete of proper consistency for moulding will segregate in transportation, whether this is done by wheel-buggies, trucks, chutes, or blow-pipe. From wheel-buggies the fluent mortar will be deposited first and the coarse aggregate will follow, but from chutes or blow-pipe the coarse aggregate will be deposited first and the mortar will follow. This latter condition is the more desirable since, in spading, the mortar envelops the stone which rises, and the mortar flows down through the interstices. It is partly for this reason that chuted concrete, or blown concrete, has given such satisfaction in field work. Another, and an important, reason appears to be the fact that the chute, or blow-pipe, gives additional mixing to the mortar as it turns over while flowing.

Attention seems to be given, by some experimenters, to the preference of having the mixture so dry that it will not segregate during transportation, but such concrete will not fill the forms properly unless thoroughly rammed and compacted, and, even then, it has been found, upon removal of the forms, that voids have been left on the surface, and similar conditions may be expected in the interior of the mass.

For many years a 1:2½:5 mixture was generally used and was considered a theoretically perfect mix, but about 1900 the 1:2:4 mix was adopted and is now (1931) established as the general standard. Wastefully rich, it seemed at first, but experience has justified its adoption as giving assurance against imperfections that will creep into practical work of magnitude. The question that remains is how to obtain the best results with this mixture. Thorough mixing is the key to good concrete. If a single mixer will not produce concrete fast enough for an extensive job, tandem mixers, or even twin mixers delivering batches alternately, may be adopted. The extra cost will be insignificant on large work, and will secure a much more uniform and satisfactory product.

---

[10] Cons. Engr., Brooklyn, N. Y.

Theodore Belzner,[11] Affiliate, Am. Soc. C. E. (by letter).—The writer has read this timely paper and Appendices I and II with great interest. The excellent and painstaking work represented by the systematic and uniform method of inspection and control of concrete manufacture, authorized and carried out to the end, is highly commendable. The value of the results secured should serve as a strong incentive to other engineers to conduct similar investigations along these lines.

Furthermore, the absolute essentials necessary for securing uniform success in producing good concrete of uniform quality, resulting from the proper training, experience, and qualifications of those responsible for this class of construction in the field, cannot be too strongly emphasized. When structures of this class are so large and when the resources of construction in workmanship are taxed to a higher degree than usual, the results have far greater value than laboratory experiments could possibly give.

John Sanford Peck,[12] Assoc. M. Am. Soc. C. E. (by letter).—This paper marks another milestone in the long struggle toward the general adoption of scientific and controlled methods of concrete manufacture in the field. Since the first promulgation of the water-ratio theory by Duff A. Abrams, M. Am. Soc. C. E., the battle to introduce his theories into practice has been a long and, at times, almost a losing one.

When Mr. Hall states, in his "Introduction," that more than 50% of the concrete made and placed to-day is of poor quality and will have a short life, he is erring strongly on the side of conservatism. The writer has yet to hear of any concrete being condemned or replaced because the test cylinders failed to meet the 28-day strength requirements; and the jobs on which sample cylinders are taken, constitute an almost infinitesimal proportion of the concrete work done in the United States. The use of "ready-mixed" concrete in large cities has gone a long step toward procuring concrete of reliable strength and durability, but even there, the room for improvement is vast.

As an example, the writer witnessed a mixer truck discharging ready-mixed concrete into the basement of a New York building. As the concrete left the mixer it seemed to be of good quality and consistency. At the top of the chute which led to the basement a workman stood with a hose, washing the concrete down. What became of the water-cement ratio in this case is easy to imagine. Such ignorance is a fair example of what still remains to be done in the line of education.

Of all the factors listed by Mr. Hall ("Irregularities in the Strength of Concrete"), which may affect the strength of concrete, the first, namely, the strengths of different brands of cement and the variation even in different parts of the same bin of a given brand, constitutes by far the most difficult variable to control. This wide variation has been long known in the laboratory. It is unfortunate that standard 2 by 4-in. compression cylinders were not included in the cement tests because it is the writer's opinion that these are a far better indication of the probable strength of concrete to be obtained from a given brand of cement than the tension briquettes. The compression tests as set forth in the American Society for Testing Materials Tentative Standards for 1930, Designation C 9-16T, should be adopted as a standard.

---

[11] Insp. of Steel and Bridge Insp. in Chg., Brooklyn Bridge, Dept. of Plant and Structures, City of New York, Brooklyn, N. Y.

[12] Instr. in Civ. Eng., College of the City of New York, New York, N. Y.

With the compressive strength of standard 1:3 cement mortars varying from 2 000 lb. per sq. in. (the American Society for Testing Materials minimum, which incidentally is too low) to 5 000 lb. per sq. in. at 28 days, the attempt to make concrete of a predetermined strength in the field is saddled with a severe handicap. The frequently expressed theory that all cements are equal seems absurd.

The account of the training and education of the field force of inspectors is worthy of more than passing comment. If the idea that special training and knowledge are necessary for the making of good concrete, could be impressed on the smaller contractors and job superintendents it might lead to the growth of a class of "concrete technologists" which in time would supplant the old-time concrete foreman or "mixer-man" who is supposedly endowed with a sixth sense whereby he knows all there is to know about concrete making.

The conditions under which the work described by Mr. Hall was done certainly were not of the easiest, and the fact that such satisfactory results were accomplished speaks volumes for the efficiency of his method of educating and training his inspection force. His experience in this regard should prove of great value in the planning of future work whether of the same magnitude or smaller, and it is to be hoped that his paper will establish a precedent for the construction industry as a whole to follow to the great benefit of the cause of good concrete.

J. W. Kelly,[13] Assoc. M. Am. Soc. C. E. (by letter).—As stated by Mr. Hall, the writer was to some degree associated with the men of the inspection force in the Louisville District during 1926, 1927, and 1928. One could not fail to be impressed with the size and variety of the project, and with the organization's policy of thorough training for the men in order to produce a uniform concrete.

An apparent lack of uniformity in the strength tests, as exhibited by the maximum and minimum range of values in Table 1, has been pointed out to the writer. However, it must be remembered that the table averages nine jobs, spread out for nearly 400 miles, with concrete made by different organizations using different types of equipment and a variety of cements, admixtures, and river-bar aggregates; also, that the percentage of test specimens which were considered defective and which were omitted from the report is much smaller than is usual on concrete work. Unquestionably, the record of each job would show a smaller spread of strength values. With specification requirements which would normally produce 1 700-lb. concrete, as stated by the author, it is evident that the average quality of the work was greatly improved through the efforts of the inspection force.

---

[13] Eng. Materials Laboratory, Univ. of California, Berkeley, Calif.

Mr. Hall's analysis of the causes of variation in concrete or in specimen strength is a clear indication of the chief features to watch in order to obtain uniform results in any concrete construction. Elsewhere in the paper he emphasizes the training of individuals, even the spaders and mixer men. This reinforces the writer's observation that the human element enters largely into concrete making, and that while the process is simple it requires intelligent and conscientious workmanship to bring a "good enough" job into the category of a first-class piece of work. First-class concrete can be made without undue effort, but too many organizations seem to be satisfied with the line of least resistance.

Improved construction practices have been strongly urged by the Portland Cement Association, particularly in regard to placing and curing. It is gratifying to note that the care taken by the construction forces on the Ohio River bear out these recommendations by their example. Improvements in the strength of cements during the course of the project are noted, as well as the practice of re-washing coated aggregates, which process would tend also to reduce variations in grading through the attendant mixing of sizes.

Inspection has too often been regarded as a perfunctory matter, tending to retard construction and to increase cost, whereas the right kind of inspection (whether for concrete or for any other construction) is one of the most worth-while investments that can be made. It is the writer's belief that qualified inspectors, preferably but not necessarily with formal technical training, are worth far more than their present scale of salaries indicates, and that their services are as real and valuable to the project as those of the designer or the construction force. More and better inspection would eliminate many of the costly mistakes, early maintenance, and construction of inferior quality that are now encountered.

After a long experience with this subject, Mr. Hall considers that sound concrete of uniform strength is best obtained by good workmanship. Better realization of this by all who deal with concrete in its many angles, is sure to result in better structures.

STANTON WALKER,[14] ASSOC. M. AM. SOC. C. E. (by letter).—The factors to which emphasis should be given in the design and control of concrete on the job, have been clearly and concisely described in this paper. There are certain points, however, which, it is believed, will be clarified by further comment.

In the paragraph headed "Specifications," it is stated that "sand was required sufficient to yield 15% or more of mortar than was needed to fill the voids in the gravel * * *." In Appendix II, under "Batch Mixing," a considerably different rule for determining the quantity of sand is inferred, as follows: "The specified measure of sand (equal to voids in gravel plus

---

[14] Director, Eng. and Research Div., National Sand and Gravel Assoc., Washington, D. C.

15% of voids) will ordinarily give only a sufficient amount when a workable mass is well mixed * * *."

The design of proportions by the first rule would result in the use of very much less sand than is ordinarily considered necessary for workability. Taking the highest percentage of "dry-and-rodded" voids reported in Table 3 (37.7%) and assuming a percentage of voids of 35 for the sand and a net water ratio of 0.9, a mix of about 1:1.3:5.1 is obtained for concrete containing 5 sacks of cement per cu. yd. by the application of the first rule. The application of the second rule results in proportions more nearly those that are ordinarily used although, in the writer's opinion, such mixes are still considerably "under-sanded" for the usual conditions. Using the same assumptions, a 1:1.8:4.4 mix is obtained. The writer would be interested in knowing which of the two rules was actually applied in the design of the concrete. In his opinion neither one of them represents a satisfactory criterion on account of the resulting "under-sandedness" of the mix. A volume of mortar equivalent to, at least, 1.65 times the volume of voids in the coarse aggregate will be required to produce satisfactory workability for the usual conditions, and this factor will vary with the size and grading of the aggregate.

A procedure for determining whether or not the test cylinders have plane ends is described in Appendix I. This is one of the most important factors in securing uniform test results and one which is often overlooked. As much of the apparent lack of uniformity in tests of field specimens is due to poor testing technique as it is to actual variations in the quality of the concrete. The writer does not agree that it is sufficiently accurate to determine by the "feel," when a cylinder is rocked on a plane surface, if the end is in satisfactory condition; it may be concave and, if that is the case, it may "feel" perfectly solid. The ends should be tested with a straight-edge or by some equally satisfactory method.

The importance of having the ends of the test cylinders "perfectly parallel" is also stressed in Appendix I. This condition is practically impossible of attainment and reasonable deviation from it is not important if the cylinders are tested in a machine equipped with a suitable spherical bearing block.

Comprehensive information has been given by H. F. Gonnerman, M. Am. Soc. C. E., on these questions.[15] While Mr. Gonnerman showed convex ends to be considerably more detrimental than concave ones, the reductions in strength for the latter condition were important. Cylinders with the top surface inclined showed no reductions in strength for an inclination of $\frac{1}{4}$ in. in 6 in., and only about 5% reduction for $\frac{1}{2}$ in. in 6 in.

Edward E. Bauer,[16] Assoc. M. Am. Soc. C. E. (by letter).—It is gratifying to note the care that was exercised in securing concrete of high quality on these particular projects. Too often the feeling exists that care and exactness have no place on the construction job; that it is only in the laboratory that these items need consideration. Mr. Hall and his assistants are to be commended for the excellence of their program for supervising the production of concrete.

---

[15] "Effect of End Condition of Cylinder on Compressive Strength of Concrete," *Bulletin 14*, Structural Materials Research Laboratory, Lewis Inst., Chicago, Ill.; reprinted from *Proceedings*, Am. Soc. for Testing Materials, April, 1925, Vol. 24, Part II, 1924.

[16] Associate, Civ. Eng., Univ. of Illinois, Urbana, Ill.

The writer wishes to emphasize the importance of attending to details in the making and testing of cylinders, in order to secure results that are uniform to any degree. Field cylinders are valuable, but unless certain rules are followed in their making and handling, the results may be erroneous and of no value. The cylinders must also be tested properly.

Mr. Hall has noted that many of his cylinders had to be capped just prior to testing, in order to secure an even bearing surface on both ends. The writer has noted in his testing work that whenever it is necessary to cap a cylinder with plaster of Paris, the crushing strength value is almost always lower than that of cylinders properly made. The ends should be made plane surfaces when the cylinders are cast in the field. It is difficult not to rock the plate or the cylinder in applying the plaster-of-Paris cap and thus produce a curved surface. The proper making of the cylinders should be given more attention by field men, in general. Cylinders that are patched up in the laboratory can not always be made to give correct results. Cylinders without plane ends should never be tested, yet one occasionally hears of this being done in some laboratory.

In Appendix I the statement is made that the ends should be "perfectly parallel." The writer sees no need for this, since the properly equipped testing machine has a spherical bearing block to be used on top of the specimen to allow for any lack of parallelism in the ends. It would seem that any attempt to secure perfectly parallel ends with an ordinary carpenter's square would be a hopeless task. While no statement is made as to whether or not a spherical bearing block was used, the precautions recommended lead one to believe that it was not. Without a spherical block there can be no positive assurance that the load is distributed over the entire cylinder. Concentration of pressure on a small area will cause the cylinder to fail at a lower load.

According to Appendix I the cylinders were kept in damp sand, the temperature of which may have varied between 60° and 90° Fahr. Tests at the University of Illinois[17] indicate that if the curing temperature after the first day is varied a uniform amount for the entire curing period, the strength is affected about 30 to 35 lb. per sq. in. per degree of change in curing temperature. The concrete in these tests showed a strength of 5 400 lb. per sq. in. at 28 days under standard curing conditions. The 1929 cylinders are fairly close to this figure, so that it may be safely assumed that the range of curing temperatures allowed on the Ohio River projects permitted a maximum variation in strength of 900 to 1 000 lb. per sq. in.

Cylinder strengths as reported vary over too wide a range. If the concrete placed in the structures was of uniform quality, then most certainly some of the cylinders did not receive the proper attention.

---

[17] See "High Early Strength Concrete," by the writer, *Proceedings,* Am. Concrete Inst., 1929.

O. Bonney,[18] M. Am. Soc. C. E., and D. T. Mitchell,[19] Assoc. M. Am. Soc. C. E. (by letter).—This paper presents and discusses a subject which is of interest and importance to all who have to do with the design and construction of concrete structures. As indicated by the author concrete of uniform quality has not always been produced in the past and experiences and information which may lead to more uniform concrete in the future are welcomed by engineers. When the art of making concrete reaches the state where uniformity is the regular occurrence it may then perhaps be possible to design structures of this material more economically.

The author emphasizes the fact that the production of concrete of uniform quality requires a thorough knowledge, on the part of all concerned, of the ingredients as well as a thorough knowledge of proportioning, mixing, transporting, placing, and curing. The engineer and the contractor are vitally cencerned and 100% co-operation is required of both.

The author sets forth under the caption, "Irregularities in the Strength of Concrete," the principal causes of the great variations that occur in "job" concrete. In this connection the writers feel that the method of mixing is a matter of considerable importance and, furthermore, that careful consideration should be given to the type of mixer used, the peripheral speed of its drum, the design of the mixing blades, the size of the drum, the mixing action, the time of mixing, and the ratio of the quantity of concrete mixed per batch to the volume of the drum.

Until recent years it has been a common practice to mix concrete in non-tilting, rotary, drum type mixers. Since about 1928, however, a type known as a truck mixer has been introduced and used on work of large magnitude, which permits the concrete to be mixed while in transit to the point of deposit, if that is desired.

Truck mixers which have come to the notice of the writers are designed to mix more concrete per batch in proportion to the total volume of the drum than the older types of mixers. Furthermore, the peripheral speed is less in the case of the truck mixer. Definite conclusions as to the effect of this on the quality of the concrete mixed in truck mixers have not been reached by the writers, but tests made on one type indicate that the mixing time for a truck mixer should be greater than that for the older type. Other tests indicated that there may be some variation in compressive strength between concrete taken from the first of the discharge of a batch and that taken from the last of the discharge. Other types of truck mixers might give different results.

During the three years since 1927 a part of what is known as the Olentangy-Scioto Intercepting Sewer has been constructed in Columbus, Ohio; this part is a rectangular, reinforced concrete structure, involving about 34 000 cu. yd. of concrete. Throughout the work attention has been directed toward making concrete of uniform quality, and the writers, therefore, submit the results of their compression tests of concrete as being of interest in connection with the results shown by the author. The results obtained on this work, together with weighted averages of those given by the author, are shown in Table 5.

[18] Sewerage Relief Engr., Div. of Eng., Dept. of Public Service, Columbus, Ohio.

[19] Field Engr., Sewer Dept., Div. of Eng. and Constr., Columbus, Ohio.

The work was divided into four sections, each section being a separate contract of the size and length shown in Table 5, Items 21, 22, and 23. With the exception of Section 4 and part of Section 1, the work was constructed in open trenches. Section 4 was constructed along the east bank of the Scioto River, the river side of the sewer being exposed. Approximately, 420 lin. ft. of Section 1 was constructed as a dam across the river.

Three brands of cement were used, one brand on Sections 1 and 4, another on Section 2, and still another on Section 3. The specifications for

* Total. † Six-month cylinders. ‡ Maximum obtained. § Minimum obtained. ‖ Job standard.

aggregate were practically the same on all four sections. The fineness modulus of the fine aggregate was required to be between 2.75 and 3.25 and that of the coarse aggregate between 6.90 and 7.50. The fineness modulus of the fine aggregate was usually found to be near the upper limit and, in fact, on Sections 1 and 2 it was necessary to add fine sand in order to obtain a fineness modulus within the limits specified. Ordinarily, the coarse aggregate was found to be satisfactory with respect to the fineness modulus. City water, softened and filtered, was used.

All concrete was mixed for 3 min. in 1-cu. yd. paving mixers of the non-tilting, rotary, drum type. The water content was controlled for the most part by the slump test. The aggregates were measured by volume at the screening plant located from 1 to 3 miles from the mixer, and then hauled to the mixer in trucks which were provided with batch compartments. An inspector was stationed at the screening plant, another at the concrete mixer, and still another at the point of final deposit.

The test cylinders were made in accordance with the Standard Methods of Making and Storing Specimens of Concrete in the Field (Serial Designation: C 31–27), of the American Society for Testing Materials, with the exception that the concrete was obtained as near the point of final deposit as possible and the cylinders were stored in damp sand on the work for only 24 to 48 hours. At the end of this time they were removed to the testing laboratory where they were then stored in damp sand or in a damp room for the remainder of the time until broken. The cylinders were broken in accordance with the A. S. T. M. Standard Methods of Making Compression Tests of Concrete (Serial Designation: C 39-27).

C. E. ARNOLD,[20] ASSOC. M. AM. SOC. C. E. (by letter).—The author presents some interesting information which indicates that with ample, proficient, and well organized supervision, concrete of quite uniform quality can be manufactured even on detached or widely separated pieces of work.

During 1928 and 1929 the writer installed 41.33 miles of storm drains to intercept and remove the storm waters from an area of 22 319 acres lying adjacent to, and immediately east of, Los Angeles, Calif. The entire system is divided into four main outlet lines, lying several miles apart, the lower (larger) portions of which are of monolithic construction, rectangular in cross-section, ranging from 6 to 10 ft. in height and from 8 to 14 ft. in width; these portions have a combined length of 13.09 miles.

The structures were designed on the basis of 650 lb. per sq. in. for concrete in compression and 16 000 lb. per sq. in. for steel in tension. Naturally the cross-section area of concrete and the weight of steel (per foot of length) varied due to the superimposed load, which was from a few feet to as much as 40 ft. of cover (in which case an arch section was used).

Three of the main lines were built simultaneously, the fourth partly overlapping the construction period of the first three. Combined, they contain more than 141 000 cu. yd. of concrete, an average of a little more than 2 cu. yd. per ft. of length. In all cases the concrete was mixed on the ditch bank in large mixers and conveyed to the structure by a traveling bucket, belt conveyor, or chute. The fine and coarse aggregates were delivered to the mixers in 5-yd. batch trucks, the contents of each batch being weighed as loaded.

---

[20] Los Angeles, Calif.

In all, 510 pairs of standard 6 by 12-in. test cylinders were made, one-half of which were tested at 7 days and the remainder at 28 days. The strength developed by the 28-day cylinders led the writer to analyze the tests which resulted in the data plotted on Fig. 4. Fig. 4(*a*) is a curve of 510 tests made on 28-day cylinders. The cylinders were made of Cements *A* and *B* and Coarse Aggregates *A, B, C,* and *E;* Fig. 4(*b*) is an analysis of 495 tests segregated to show any difference in strength, due to the brand of cement used; Fig. 4(*c*) is an analysis of 507 tests segregated to show any difference in strength due to varying the brand of coarse aggregate; and Fig. 4(*d*) is the result of plotting curves of the 510 tests in classes according to the slump. It was thought that a higher unit concrete stress (about 800 lb. per sq. in.), might be used in future designs, which seems justified since only 4% of the tests showed strengths less than 2 500 lb. per sq. in. The writer would appreciate the author's comments relative to such an increase.

Inspection.—One chief storm-drain inspector, a graduate from a reputable engineering school, was employed to supervise and to assist, when necessary, the inspectors stationed on the job. The inspectors on the monolithic work were experienced men (some had been with the writer for more than three years), who knew the importance of the water-cement ratio, the fineness modulus, and the necessity for a workable mix. They were extremely loyal and more than faithful.

Tests.—More than 500 tests were made on the cement, by a reputable laboratory, before its delivery to the job. The average of these tests shows that 12.7% of the cement was retained on the No. 200 screen. The average tensile strength of 7-day standard briquettes was 330 lb. per sq. in. and 412 lb. per sq. in, at 28 days.

All test cylinders were made by the laboratory personnel; they were stored in wet sand for 24 hours and then removed to the laboratory. Concrete for the test cylinders was taken from within the forms immediately after it had been placed. Slump tests were made at the same time, the average of three being used.

Materials.—Cement was furnished from two mills, and the results obtained by their use were practically identical (see Fig. 4(*b*)). The tensile strengths of standard briquettes were quite uniform and nearly identical for both brands. Both fine and coarse aggregates were furnished by four firms. Aggregates *A, B,* and *C* (see Fig. 4(*c*)) came from the San Gabriel River, Washington; they were identical in character and quite uniform as regards size. Each of these coarse aggregates contained not more than 30% of crushed boulders. Aggregate *E* was furnished from a pit; it was slightly different in character, contained no crushed material, and was not as well graded as Aggregates *A, B,* and *C.* The results obtained by its use are quite plain.

Fig. 4(*a*) shows the results of all tests on 28-day cylinders. Fig. 4(*c*) shows the analysis according to the slumps. It will be noted that slumps of

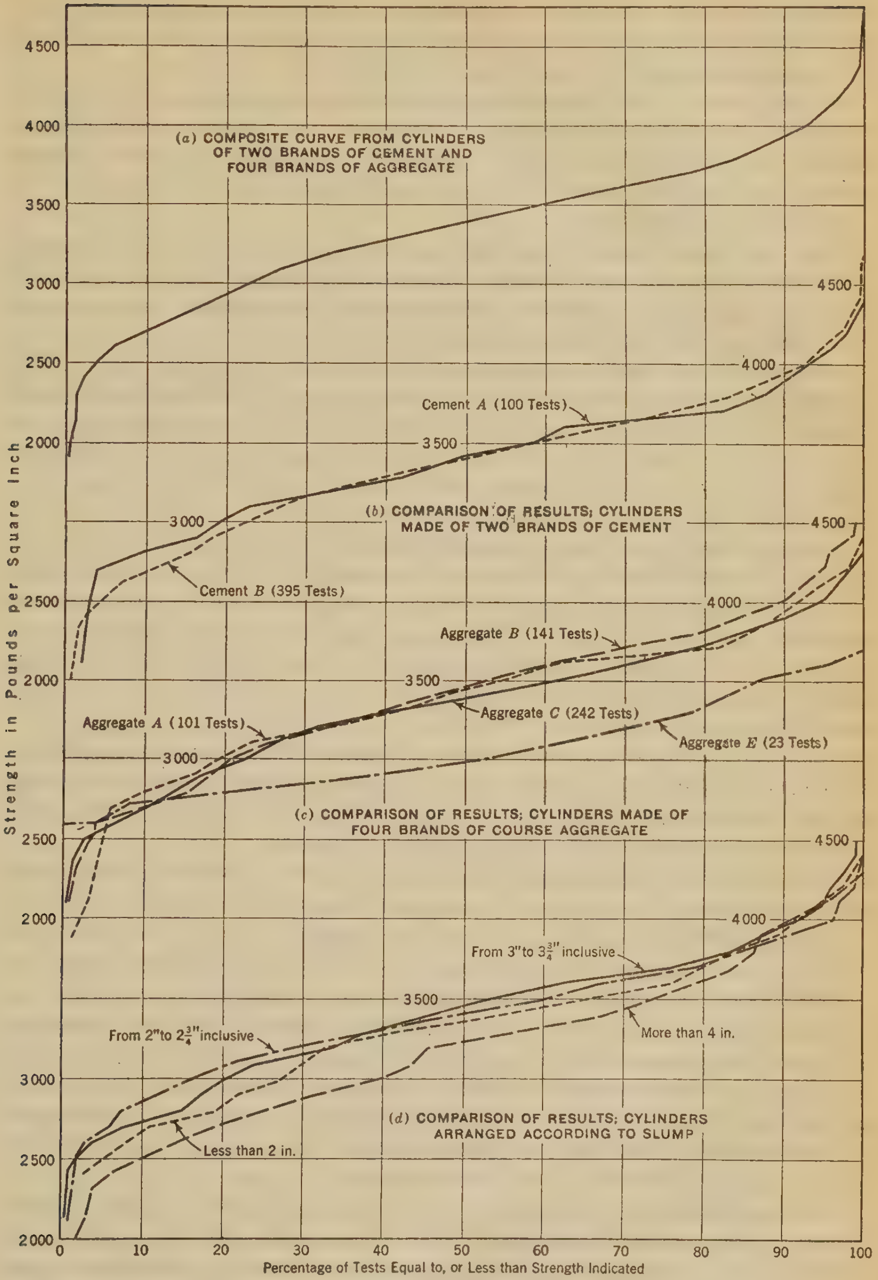

FIG. 4.—COMPARISON OF TESTS RESULTS ON CONCRETE CYLINDERS BY SEGREGATION OF VARIABLES.

less than 2 in. did not give the strongest concrete for this particular mix. From these results it would appear that the best concrete would be obtained by using a slump varying from about 2 to 3¼ in.

Specifications.—The following comments on the specifications under which the work was done, are included in order that the results may be rightly judged. All cement was required to meet A. S. T. M. Standards (Serial Designation, C9–26). Class A concrete, as defined by the specifications, was used in all reinforced work.

Fine Aggregate.—It was required that fine aggregate for use in concrete or mortar consist of hard, durable, mechanically washed particles resulting from the natural disintegration of rock, having clean grains uncoated with clay, alkali, or oil, and free from organic matter.

When ready for use it was required to be so graded that not more than 6% (by weight), including the loss by decantation (A. S. T. M. Standard; Serial Designation, D136–22T) passed a No. 100 sieve; not less than 17%, and not more than 42%, passed a No. 30 sieve; not less than 60%, and not more than 85%, passed a No. 10 sieve; and not less than 93% passed a ¼-in. round opening screen. All passed a ½-in. round opening screen.

Coarse Aggregate.—Coarse aggregate for use in concrete was specified to consist of crushed stone or gravel or a combination of gravel and crushed stone. It must be hard, mechanically washed, and have clean surfaces uncoated with silt, clay, alkali, oil, or organic matter. It must have a specific gravity of not less than 2.50 and must have a French coefficient of not less than 9 when subjected to the Deval abrasion test (A. S. T. M. Standard; Serial Designation, D2–08).

When ready for use, it must contain not more than 30% of crushed stone; it must be graded so that not less than 95% (by weight) passed a 1½-in. round opening sieve, but not more than 7% passed a ¼-in. sieve, and not less than 30%, nor more than 55%, passed a ¾-in. round opening sieve.

Concrete.—The specification for Class A concrete required that it be composed approximately of the relative volumes of materials as follows: 1 cu. ft. of cement; 2 cu. ft. of sand; and 4 cu. ft. of gravel.

In all concrete, the volume of the sand and gravel could be varied as directed by the Engineer of Construction, but for Class A concrete, the sum of the volumes of sand and gravel (measured separately) must always be 6 cu. ft. The volume of sand specified for Class A concrete was on the basis of dry sand. The volume of any sand containing moisture could be increased as determined by the Engineer of Construction, in quantity sufficient only to allow for the bulking due to moisture content. No increase could be allowed in the volume of rock due to moisture content.

In Class A concrete, only sufficient water could be used to produce concrete having a slump of not to exceed 4 in. All concrete, whenever practicable, was mixed in batch-type mixers and Class A concrete was always so mixed.

It was required that the mixer drum have a speed of not less than 13 rev. per min., and each batch must be mixed in the drum of the mixer not less than 1½ min.

In the locality of this work, coarse and fine aggregates cost so nearly the same that there was no objection on the part of the contractors to changes in the proportions used. For this reason (and to avoid frightening the contractors by the inclusion of a fineness modulus specification, thus increasing the cost), the provision in the specification relative to the variation in percentage of fine and coarse aggregate was included and was freely used by the writer to secure a uniform workable mix. The proportions actually used on the work varied between the following limits: Cement, 1 part; fine aggregate, 2.25 to 2.35 parts; and coarse aggregate, 3.75 to 3.65 parts.

The writer feels that an analysis of the author's tests in a manner similar to that shown on Fig. 4 would be of value to the Engineering Profession. With the present knowledge of the manufacture of concrete and the methods and equipment available for testing the materials, a general increase in the unit working stress is in order. The presentation of such papers as that of Mr. Hall will enable engineers to judge, more correctly, the extent to which an increase seems advisable.

MORRIS MASON,[21] JUN. AM. SOC. C. E. (by letter).—It has been stated by Mr. Hall that the more scientific methods of concrete control have produced a more uniform concrete. Others have found that a designed strength of concrete may be produced at a lower cost by the application of these methods. If this is true, it is difficult to understand why the application has not become more general; but engineers show a great deal of stubbornness in maintaining formulas and rules which they have found to be usable, although not perfect.

In Appendix II, the statement is made that "hostility is one of the greatest obstacles to the control and inspection of concrete construction." This is the prevalent attitude on many concrete jobs. The engineer often encounters the following attitude among the men in charge of concrete work: "I was pouring concrete twenty years before your method was devised. I have poured good concrete and can continue to do so." Steel was made successfully for many years, by the same type of methods which are now in use in mixing concrete, but no steel company would consider using such methods under present conditions.

A number of methods of concrete control have been used successfully in the past. The Illinois State Highway Department has followed the "mortar-voids" method. The "surface-area" method has been used to some extent and the "water-cement-ratio" method has also been very generally adopted with success. A conclusive proof of the advisability of these methods is given in the fact that when any of the newer methods is used, the old "trial-batch" or "fixed-ratio" methods are not reinstated. It is left to the decision of the engineer as to which of the methods is more usable on the particular work with which he is connected. Even if the application of the method be imperfect, "a poor estimate is better than a good guess." The reports on these methods are unanimous in that more uniform concrete can be produced at a lower cost.

---

[21] Engr., Standard Oil Co. (Indiana), Wood River Refinery, Wood River, Ill.

When the practical concrete man has grasped the advantages of these methods he is generally in favor of their continued use, because he sees the improved quality and uniformity of the concrete. Excessively sloppy mixes are slowly being condemned. The presentation of conclusive proof that better concrete can be produced, even under adverse circumstances, as has been shown in this paper, will hasten the discarding of many of the older methods of concrete control.

John H. Griffith,[22] M. Am. Soc. C. E. (by letter).—The writer is interested in this paper because of the information afforded as to the range of variation to be expected in systematic analyses of concrete laid under first-class conditions of fabrication, control, and tests. He believes that a higher degree of efficiency could be obtained than is usual in the testing of concrete if the capping of cylinders could be replaced by grinding the ends of specimens to a true plane approximately normal to the axis of the cylinders. This is easy with a cast-iron disk mounted horizontally and rotating about 30 rev. per min. Ottawa sand is a good abrasive. A number of cylinders can be handled simultaneously with very little watching, the proper pressure being supplied by their own weights. Both brick and hollow building tile develop higher and more uniform strengths by this method than by the older methods of capping. As Mr. Little has remarked in Appendix I the operator cannot be sure of a plane surface in capping and by the use of an intermediate paper. As he rubs the cylinder on a steel plate in any case, he need only carry this a little further to get a perfect job once for all, and without rocking and other expedients.

The ideal theoretical method for mounting silicate specimens in compression is the hydraulic bearing originated by Mr. Mont Schuyler[23] formerly of the Municipal Laboratory at St. Louis, Mo. This method in principle consists in mounting the specimen on a hydrostatic base, eliminating entirely the uncertain and quite considerable radial friction developed under pressure by the concrete expanding radially under test. The common method of frictional reinforcement at the base produces a cone-shaped fracture, while the test under a pure compression gives vertical planes radiating from the axis of the specimen 120° apart. The method proposed by Mr. Schuyler needs mechanical development since there is the problem of a possible "blow-out" under the high pressures involved. While the surface grinding method has some radial friction, the writer believes that it will give efficient test results as high as or even higher than Mr. Schuyler's method as a result of the perfect square ends and because the vertical filaments are under a minimum of eccentricity, there being scarcely any incipient local failures by this method.

Rather frequently in testing practice use is made of hemi-spherical heads that are likely to "stick" as a result of gumminess and infrequent oiling. It is a good plan to give a hurried wiping and squirt of oil to these heads preliminary to every test so that they are sensitive to every eccentric load however slight. This plan avoids applying test loads at the peripheries of specimens, such that they lower the intrinsic strengths of concrete. Too often this danger is not realized in practical testing. One should seek to develop the full theoretical strength of a specimen even if it is difficult always to attain it in practice.

---

[22] Prof. of Experimental Eng., Iowa State Coll., Ames, Iowa.

[23] "Spherical Bearings," by Mont Schuyler, *Proceedings*, Am. Soc. for Testing Materials, Vol. XIII (1913), p. 1004.

The following method has been found of general utility in making specific gravity, displacement, and absorption tests of the silicate products, including sand, rock, refractories, and concrete. It has the advantage of being performed either on a small or a large scale, with practically any sort of container, a pycnometer, an Ehrlenmeyer flask, a Schuette cone, a can with a constant level spout, or even a pail. Three-figure accuracy is possible with reasonable care, and four figures by careful work with temperature correction determinations. It is a method of differential weighing; the equations are as follows: Let the tare of the receptacle be represented by $W_0 = w_0$. The weight of the container filled with water to a mark or to the top equals,

$$W_1 = w_0 + w_1 \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (1)$$

and the weight of the container, the water to the same mark, and the weight, S, of the specimen, equals,

$$W_2 = w_0 + w_2 + S \ldots\ldots\ldots\ldots\ldots\ldots\ldots (2)$$

Subtracting Equations (1) and (2),

$$W_2 - W_1 = S - (w_1 - w_2) = \Sigma\, w - \Sigma\, \frac{w}{t} = \Sigma\, w\left(\frac{t-1}{t}\right) \ldots\ldots (3)$$

in which, $\Sigma\, w = S$, is the weight of the specimen in terms of its separate components, if any, either intact or powdered in a mortar to suit, and sifted, and $\Sigma\, \frac{w}{t}$ is the summation of the displacements of components in terms of the specific gravities. The displacement, in grammes or cubic centimeters, of the specimen, $S = \Sigma\, w$, is $w_1 - w_2$.

In the tests of the silicate products, $\frac{t-1}{t}$ is approximately the fraction, $\frac{5}{8}$, and is to be chosen subject to the statistical experience of the operator or determined by sufficient check tests. Since the specific gravity of water is ordinarily taken as unity, $\frac{t-1}{t}$ for water vanishes. Hence, there results (to a close degree of approximation):

$$\tfrac{8}{5}\,(W_2 - W_1) = \Sigma\, w = S_d \ldots\ldots\ldots\ldots\ldots\ldots (4)$$

for the dry weight of the specimen, and for the absorption of water, $S_w - \frac{8}{5}\,(W_2 - W_1)$, the other elements of the specimen, if any, being found by sieve separation in the usual manner, dry or wet according to circumstances. The figures for a run of wet concrete will demonstrate its inherent advantages as an expeditious method, the process being still quicker in the cases of paving and building bricks, and refractories (see Table 6). A constant level container was used.

The difference between Items 3 and 2, Table 6, is 3.280 kg. Taking eight-fifths of this gives the dry weight of the mix as 5.248 kg. Subtracting this value from Item 8, Table 6, gives 0.377 kg. in contrast to 0.375 kg. for the original weighed water (which, of course, is frequently unknown in practice).

The specific gravity of Ottawa sand, using a 10 or 20-gramme sample in a pycnometer, can be found by the method mentioned herein so as to give the order, 2.65, as usually recorded with repetitions within the range, 0.01, sometimes recommended. For refractories and paving bricks it has been found that five samples can be tested in the space of a few minutes using a 10-gal. pail with a "fiduciary" pencil mark on the inner surface of the pail to give results of the orders published by the authorities. In the case of relatively non-absorbent materials like paving brick, scarcely any water can be absorbed in the short interval of the test. When absorption tests have been run, the true or apparent specific gravities are quickly found without pulverizing materials, which is sometimes a factor in hurried determinations.

TABLE 6.—WEIGHT OF A MIX, APPROXIMATELY SOAKED, BUT DRY ON THE SURFACE

Item	Symbol	Weight, in kilogrammes	Description
1	W_0	2.216	Tare
2	W_1	12.990	Container and water
3	W_2	16.270	Container, water, and specimen
4	w_g	3.000	Gravel
5	w_s	1.500	Sand
6	w_c	0.750	Cement
7	w_w	0.375	Water
8	S_w	5.625	Wet mix

In making routine tests it is advisable to obtain once for all, the values of W_0 and W_1 as averages from a number of determinations. Using an empty, dry receptacle the sample is then best weighed for the gross, and the water filled to the mark later to give W_2. In general, by the use of a strictly differential method with as few manipulative operations as possible high efficiencies are obtainable with few losses due to transfers and other handlings.

It is the purpose herein to give the writer's experience in testing rather than to criticize Mr. Hall's valuable paper on the difficult problem of handling a synthetic material.

W. B. WENDT,[24] M. AM. SOC. C. E. (by letter).—This discussion is confined to tests made at the laboratory of the University of Louisville, begun in May, 1928, as presented in Table 1 of the paper. The compressive strength of the 1929 concrete averaged the highest for the five years and the variations of Item 3 from Item 2 and of Item 4 from Item 2 (Table 1) are considerably less for 1929 than for any other year, as shown in Table 7.

The percentage differences in Table 7 show conclusively that the quality of the 1929 concrete was much more uniform than that of other years, and that the continued insistence on more uniform and better concrete on the part of inspectors on the job was bringing results. As the writer

---

[24] Prof., Civ Eng., Speed Scientific School, Univ. of Louisville, Louisville, Ky.

understands it, one of the main objects of Table 1 was to point out that good concrete could be obtained and that it would be fairly uniform.

The nine jobs were spread out for nearly 400 miles, and concrete was made by different organizations using different types of equipment and a variety of cements, admixtures, and river-bar aggregates. It is because of these conditions that the small variation in test results for the year 1929 is remarkable.

Capping and Storing the Cylinders.—The method of rocking a cylinder by hand on a plane surface (or by the "feel") as reported in Appendix I, was not the only method used to determine whether the ends of the test cylinders were truly plane surfaces. At the laboratory, the rocking of the cylinder was only one of several tests to which the cylinder was subjected to determine whether the ends were satisfactory for testing. Each cylinder was given a thorough visual inspection and each was also subjected to a steel straight-edge, when considered necessary. The cylinders were tested with a spherical bearing-block in the testing machine, and, therefore, no error was caused by eccentric pressure due to any ends not being parallel.

Contrary to current belief it is quite possible to apply the plaster-of-Paris cap without rocking the plate or the cylinder in such a way as to produce a curved surface. The method of procedure is as follows: The plaster of Paris is mixed with water to produce a paste of very plastic consistency. The correct quantity (determined by experience) of this paste is applied to one end of the test cylinder. This end is immediately placed on the bottom machined plate, and the cylinder is rotated and pressed down on the plate by hand until the thickness of the plaster of Paris is about $\frac{1}{8}$ in., or less. The paste is then applied to the upper end of the cylinder. A machined plate is immediately placed on this upper end of the test specimen and the cylinder pushed into position in the testing machine with the upper and lower machined plates still in place. The moving head of the testing machine is brought into contact with the upper plate, a load of several hundred pounds is applied to the test specimen, and this load is kept on until the plaster of

Paris becomes hard, requiring at least 15 min. The cylinder is then tested to failure. The writer has examined several hundred of these plaster-of-Paris caps after removing the test specimen from the machine, and he has never found one with a crack that indicated any signs of failure.

Cylinders should not be discarded because the ends of the test cylinder are not parallel. They are made in the field in an endeavor to ascertain the strength of the concrete. When these cylinders reach a testing laboratory, the laboratory technician must test them, using every precaution to insure that the test results will have value. The writer used the plaster-of-Paris cap in an effort to secure pressure distribution over the entire surface of the test specimen. All the testing machines used are equipped with spherical bearing-blocks, because it is hopeless otherwise to expect results to have any value. The test results on pairs of cylinders made of the same concrete check remarkably well, and it might be well actually to compute the variation from the mean of each pair of cylinders in order to show just how close the check was.

In many pairs the breaks of the two cylinders were remarkably close, and, in fact, two pairs under loads of nearly 200 000 lb. were recorded as nearly equal as could be read on the pulling arm, 5 ft. long, the sensitivity of which was 10 lb.

All cylinders received from May, 1928, were tested either by W. R. McIntosh, Assoc. M. Am. Soc. C. E., or by the writer.

William M. Hall,[25] M. Am. Soc. C. E. (by letter).—It is gratifying to note that there is much unanimity of opinion in reference to the advisability of teaching and training inspectors (even after graduation from the best engineering schools) as to "job" methods, system, and technique, and the treatment and training of the men who do the real work of delivering, measuring, and mixing materials, and transporting, placing, and curing the concrete.

The writer agrees with Mr. Seaman in his statement as to quality requiring "more than uniformity," and that it should be of uniform good quality. It is desirable to secure such uniformity for every batch of concrete, and the record thereof, as indicated by every cylinder, should be made. All the details he names—thorough mixing, sufficient caution in "moulding" or placing to overcome the segregation resulting from transportation, thorough "spading" next to forms to give a mortar face on every stone or gravel, and thorough spading in the body to release the bubbles of air entrapped when dumping—are desirable or requisite. Such uniform care day after day, month after month, and year after year, can scarcely be attained except by selecting those inspectors and operatives in whom some pride and enthusiasm can be inspired for accomplishing good work, or better work than that which is just passable. When forms are removed, each man trained for his particular work, or part of the work of each monolith, should make an inspection of the finished work with a diagram in hand, showing the engineer in charge the part done by each. If systematically done, this tends to perfect such good accomplishment and interest in the finished work.

---

[25] Civ. and Cons. Engr., Parkersburg, W. Va.

Possibly, Mr. Peck's exception to the statement that 50% of the concrete made to-day has a short life, is well taken. It is to be hoped that such is the case, but that 50% is below the average quality is believed to be unquestionable, and much below the quality of most of the concrete tested and reported in Table 1, for the four years, 1926 to 1929, inclusive. A careful reading of Mr. Peck's comments following that statement tends to confirm the accuracy of the writer's estimate of poor concrete. Possibly 50% is a little high and possibly Mr. Peck has not seen so much concrete, not only poor, but failing, as it has been the writer's misfortune to see.

As Mr. Kelly, who had some years of association with Professor Abrams, was the principal and invaluable aid in conducting the training school for inspectors, he fully understands its importance, and, on large structures, the importance of perfecting and systematizing methods of directing the workmen and conduct of the work by any new assembly of inspectors, such service as he rendered is almost invaluable.

Mr. Walker's exception to the specification of "15% or more of mortar than was needed to fill the voids of the gravel," is well taken. The actual practice throughout all the work was (as stated in Appendix II under "Batch Mixing,") "the specified measure of sand (equal to voids in gravel plus 15% of voids)" and, in addition, due allowance was made for bulking where an inundator was not used in measuring the sand. In fact, emphasis was always placed on the importance of preventing any misunderstanding and of always having uniformly workable concrete. It is known that with the mortar specification in force, unless the sand carries an unusual quantity of fines, or unless an admixture is used, a harsh product may result. Therefore, the "plus 15%" of sand was the adopted practice, emphasis being placed on "workability."

Professor Wendt submits his comments on laboratory practice, in breaking test cylinders made on this work. The answer to the questions raised by Messrs. Kelly, Walker, and Bauer and by Professor Griffith will be found in this discussion. It is observed that the impression was given that the method of rocking a cylinder by hand, or by the "feel," was the only one used. As affirmed by Professor Wendt, this was not the case; however, it appears the simplest and one of the best for efficiency, and minimum time is required by the laboratory technician for that test.

In the paper, under the heading "The Concrete Inspectors," reference was made to nineteen pairs of cylinders at Auxiliary Lock 41, at Louisville, and tested at the age of six months. Fig. 5 is a view of some of these job cylinders after testing (from left to right, Cylinders Nos. 54, 53, and 71). Cylinders Nos. 53 and 54, tested at the age of six months, were subjected first to 200 000-lb. pressure without breaking. A month later Cylinder No. 53 broke at a pressure of 194 000 lb. Cylinder No. 71 broke, at six months, under a pressure of 182 820 lb., as reported in the paper. Note the numerous sheared pieces of gravel.

It is gratifying to have such an extensive exchange of experience on the important details of laboratory technique; however, the writer will add a few explanatory words. As an example of the practice, Appendix I describes only the making and finishing of cylinders in laboratories "on the job." Professor Wendt's remarks are all in reference to the treatment after the cylinders are transferred from the field to the University Laboratory—two entirely different parts of the process by different personnel. The writer has emphasized the importance of completing the cylinders entirely and curing them "on the job" to within about five days of breaking, thereby reducing the chance of fracture in transfer to a minimum. After arrival at the Laboratory, it was the exception for a cylinder to require more than an examination of the ends and its general condition. It was then immediately placed in storage for curing until the hour of breaking. Each cylinder requiring new plaster-of-Paris ends consumed from 15 to 30 min. additional. Hence, the detailed description of the two processes, and the effort to prevent re-capping with plaster of Paris.

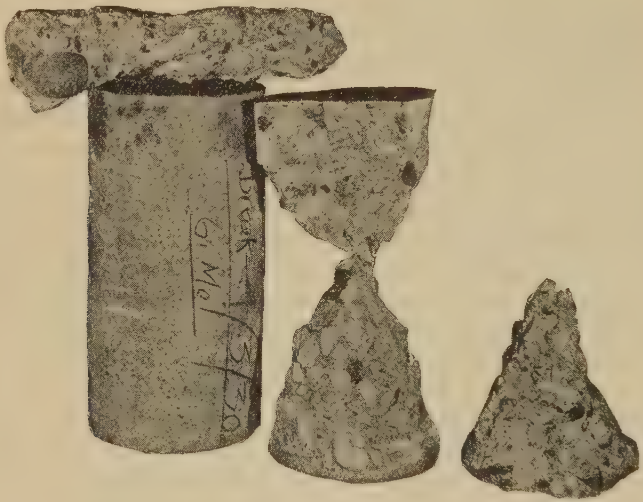

FIG. 5.—CYLINDERS BROKEN AT SIX MONTHS.

Preceding the engagement with Professor Wendt for breaking the cylinders, all the other cylinders included in Table 1, were broken by or under the personal direction of Herman H. Heck, Chemical Engineer, in a laboratory equipped and operated by the Byllesby Engineering and Management Corporation. Mr. Heck states that the methods of treatment, and the use of spherical head for applying and equalizing pressure conformed throughout with Professor Wendt's procedure. As regards finishing the ends of cylinders in field laboratories, it may be said in full justice to Mr. Little, that he has tried numerous methods of perfecting cylinders and, compared with the others, the "feel" appears to be the final test in his field laboratory for giving the best results, and the writer has observed no better method.

Messrs. Bonney and Mitchell who give such a good record of work accomplished for the City of Columbus, Ohio, are fortunate in the accomplishment recorded in Table 5. Mr. Arnold and the Los Angeles land owners are nearly as fortunate in obtaining concrete of about the same uniformity as that in Table 5, although with not quite so high an average strength. As the drains described are not subjected to freezing (which makes the question of waterproofness a minor factor of design), it appears that, should the uniformity in strength of the concrete be maintained it would be good practice to reduce the measure of cement to produce concrete slightly exceeding the designed strength. In fact, that is one of the most important reasons for such tests. It is regrettable that many other records of such uniform concrete were not given by other engineers or contractor managers. It adds to the evidence that such uniformity is only a question of training engineers, inspectors, and workmen, and that when owners become informed as to the increased durability of their structures, built of concrete of such uniform quality, it is probable that such methods and results will be demanded by them.

The writer wishes to express sincere appreciation and thanks to all who have contributed to this paper, including all those who took part in the construction described, and especially to all those with whom he was intimately associated in any part of the construction or testing work.

AMERICAN SOCIETY OF CIVIL ENGINEERS

Paper No. 1817

SOME REFLECTIONS REGARDING ENGINEERING PRACTICE

ADDRESS AT THE ANNUAL CONVENTION, YELLOWSTONE NATIONAL PARK, WYOMING, JULY 6, 1932

BY HERBERT S. CROCKER,[1] PRESIDENT, AM. SOC. C. E.

It is safe, I think, to say that the minds of most engineers, at present are not overburdened with work. Such being the case it is only natural that they should be indulging in a great deal of solemn reflection concerning the internal problems of their profession; not only the problems of long standing but those which are bound up with the future.

My own reflections have had to do mostly with structural design and administration of construction work, since that is largely my field. There are two questions which I wish particularly to discuss. These questions may appear superficially to be unrelated, but since they affect every construction engineer profoundly, and every civil engineer to some extent, they may plausibly be discussed together. One is the sore question of the relations between those who design and supervise (the engineers) and those who undertake and execute (the contractors). The other is the question of the character which the work of the civil engineer may be expected to take in the future, of the opportunities which lie ahead not only for the experienced engineer but for the young engineering graduate. What I say must necessarily be taken merely as the speculation of an individual, based upon his personal experience and observation (which may be very different from that of other members of his profession). Also the matters discussed are controversial and are not susceptible of exact analysis. It may be profitable, nevertheless, to touch upon them.

In the earlier stages of engineering practice in the United States, there seems to have been a well defined line of demarcation between engineers and contractors. The contractor was a practical man in the most literal sense of the word; without especial pride in his important function; not overburdened with scruples as to the quality of his work so long as it yielded him a profit. If he found an opportunity to cut his costs, even though it meant a sacrifice of quality and workmanship, he seldom hesitated to take advantage of it. Indeed, this was sometimes a matter of pride with him.

---

[1] Cons. Engr., Denver, Colo.

The engineer on the other hand, both by education and technical training, held to a superior attitude. It was necessary and right that he should. As maker of the plans and specifications he was even more intimately acquainted with the detailed character of the work than was the owner himself. As the representative of the owner he also assumed the position of sole judge of the quality of materials and workmanship. His, in short, was the last word on any construction enterprise and he drew his specification accordingly.

This was, as I say, necessary and right at the time; but it led to a well-defined antagonism between the engineer and the contractor which has scarcely redounded to the benefit of either. The contractor frequently saw in the engineer, his enemy—the man whose principal aim, according to the contractor's point of view, was to keep a profit from being made. The engineer frequently saw the contractor, on the other hand, as an ever-present obstacle to good workmanship, a necessary evil who must be borne with, but only grudgingly. He usually approached the contractor in a spirit of suspicion, sometimes even with malice, and there were even engineers who held that they had not done their duty if the contractor did not wind up with a loss.

In recent years this situation has changed to a considerable extent. The traditional antagonism still hangs on here and there, but for a number of excellent reasons it has begun to die out. The experiences of the World War, when everything was subordinated to the one goal, had much to do with this. For another thing, there have been marked changes in the personnel of construction organizations. The increasing size of construction projects began to reveal the inadequacies and defects of the old-fashioned "practical" contractor. The more far-sighted contractors began to find that the technical man had much to offer them; and then began the infiltration of qualified engineers into the contracting service. To-day, many members of this Society are engaged in this work. The result of this introduction of engineers into contracting has been, naturally an improvement in the ethical standards of field management. Another important factor, of course, has been the laudable progress made by The Associated General Contractors of America in the promotion of higher standards of integrity in construction. As in many other lines of endeavor, it has become apparent that good workmanship is good business—that slipshod and "skimpy" construction is not, in the long run, really profitable. The "satisfied customer" is as great an asset to the contractor as to any other business man; perhaps even greater, for a construction contract is never entered into lightly and past reputation is frequently the deciding factor in awarding a contract. Still another influence in the improvement of the status of contracting is the contractor's realization that without close co-operation no work of construction may be carried on efficiently or with complete satisfaction to any of the parties concerned. Contractors taken as a body are to-day more reliable, more efficient, and more co-operative than ever before. Do not understand me to say that contractors have become perfect. Many "sharpshooters" are still to be found in the business and, on account of these, the unilateral contract is still a necessary club; but as a club it should be used sparingly and with discretion when a contractor is endeavoring to do good work.

During the upward progress of the contractor, how has the engineer occupied himself? He has made great advances in technique, in the knowledge of design, and in the art of construction; he has prepared himself by research, by careful technical training, and by experience, for the handling of works of hitherto undreamed magnitude. Not only that, the nature of his training has opened to him the field of executive management. Engineering training, with its emphasis on accurate analysis and close thinking, has proved itself of great value in the business world. The engineering-trained executive, placed in positions far removed from the actual technical problems of engineering, is now a commonplace.

But how about that difficult relationship between the engineer and the contractor? The contractor has made his advances toward a more satisfactory relationship. Has the engineer done his part? The answer, of course, is that in the minds of many engineers a great gulf still exists between the two. Contracts and specifications are still written upon the assumption that this gulf shall not—or cannot—be bridged. Many engineers, as individuals, still entertain the old hostility. There is a need for greater recognition of the unity of purpose by which the two are actually joined, and it is plainly up to the engineer to do his share in making this unity apparent.

The engineer should, in many cases, cast aside his "superiority complex," and recognize the qualified contractor as his co-equal, within the sphere of his special field; but the question of how this shall be done is not an easy one to answer.

One of the most difficult obstacles is the practice among engineers of placing upon their work as inspectors young engineers fresh from college, inexperienced, full of zeal, and with an abiding faith in the infallibility of plans and specifications. These become the rule and guide of their conduct, admitting no exceptions. Such faith in the infallibility of specifications is beautiful to behold, but hardly justified. If a perfect and all-inclusive set of specifications has ever been written, it has not been my pleasure to see it; and if so interesting a document exists anywhere it should be suitably enshrined where it may become the object of engineering pilgrimages.

Since such documents are so rare, it often happens that minor changes are either necessary to good workmanship or may be helpful to the contractor and at the same time be of benefit to the work. It is manifestly unfair, both to them and to the contractor, that young inspectors should be required to pass upon such points. Decisions of this kind require a background of experience and mature judgment which they cannot be expected to possess. The ideal inspector is capable of making fair decisions without the fear that the contractor may be deriving some hidden and diabolical advantage from them. A successful contractor usually has a fund of knowledge gained from practice—experience that stands him well in hand and that deserves the respect of any engineer. If relations between the contractor and the inspector are satisfactory, this fund of practical knowledge is available to the engineer at all times and he should not be afraid or unwilling to use it. The inspector most dreaded by the contractor is the young man who fears to depart from the letter of the specifications because of his inability to evaluate the advantages and disadvantages of such a departure.

Furthermore, in these days of highly competitive bidding and small margin of profit, a literal adherence to the plans and specifications in non-essential requirements may frequently change a profitable contract to a losing one without benefiting the finished product in any way. The old sport of "wearing out" a contractor is a vicious one, and we may frequently assume that the engineer who plays it is not an engineer of the best type. Rational practice requires that the field engineer in charge be a man of experience, endowed with sound engineering judgment and common sense. He should be capable of assuming responsibility and should be empowered to exercise it within reasonably broad limits; and he should be well paid for his work. Responsibility, also, should be on the job, not lodged in some distant office where the immediate requirements and peculiarities of the work are not known. In foundation work, for example, delays may be hazardous both physically and financially.

This is, in short, a plea for placing engineers of high calibre on the work and endowing them with greater powers of discretion than is now customary. It is a plea for recognition that the end of construction work is construction, and that the engineer charged with its immediate supervision is as important as the engineer engaged in design or remote supervision.

In Federal and State work this question of the relationship between engineers and contractors has peculiar difficulties not found in work of a private character. Both Federal and State highway departments are to be commended for the speed with which they have built up efficient organizations for the construction of a wonderful system of public highways during the past decade. However, owing to the handicaps of civil service and political preferment, they have been unable in many cases to place the field handling of the work in the hands of the experienced. This compels remote control, which, together with the necessity for dual supervision in the case of Federal Aid projects, has resulted in useless expense and unnecessary hardship to many capable and honest contractors. Many Government engineers are aware of these difficulties. How the difficulties may be overcome is a problem involving time, patience, and careful study by broad-minded engineers. I suggest that the qualifications of the men placed in charge in the field is the most important point to be considered.

So much for an old and difficult problem. I come now to another point, and one which is of even more concern to every engineer now engaged in construction work. I refer to the outlook for the future as it concerns these engineers and the young engineers who look forward to establishing themselves in this branch of the profession.

During the recent years of inflation, which were reflected among us by a tendency toward specialization and a feverish desire to outdo the magnitude of previous efforts of construction, engineers had difficulty at times in securing qualified assistants. (A qualified engineer I take to be one who possesses qualities of experience and ripened judgment, as well as of common sense and technical training.) Such well-rounded men were not to be found in sufficient quantity.

But that day is past—whether permanently or not no one can say. We have now entered into a period of smaller things, involving—so far as we are concerned—construction enterprises of less individual size. And although it may seem heresy to say so, I see in this new situation elements of possible benefit to the younger engineers. Huge organizations with centralized authority, as we have found out, do not solve all our problems. With the breaking down of many of them, and the dissolution of the mergers and combinations which brought them into being, construction is very likely to be resumed by smaller units. Each of these will contain all the elements that were contained in the larger. This means that instead of being swallowed up in a large enterprise and hence being forced into a one-sided development through over-specialization, the engineer may find himself in a more important and responsible position in a smaller concern. Engineering opportunities may be multiplied and diversified through local handling of construction. It may be that the field will open up once more for local consultants.

I think that whatever such a development might mean from the position of the economist, there is no doubt of its benefit not only to the individual engineer but to the profession. How much better for both that the young engineer should find opportunities and recognition in his own community than that he should be—as the bulk were rapidly coming to be—condemned to work in a narrow field.

It seems plausible that the answer to the question—"What is to be the future of our engineers in private practice?"—may be found in some such economic development. One need hardly fear that the collapse of the merging habit, which was carried to such extravagant lengths during the past decade, will dim the future of the engineer in private practice. On the contrary, it brightens it, and enlarges the opportunities for more well-rounded development of the younger engineer. Meanwhile, the opportunities for consultants, for pure technicians, and for those engaged in private practice, will still be open.

Another attractive field for the young engineer has been opened—as I have already suggested—in the contracting service. It will interest many to know that at present about 2 400 members of this Society, comprising about 16% of the total number, are engaged in this work. This proportion will unquestionably increase in the future, and by this leaven the improvement in the ethics and business standing of contractors will be carried still further—thus, incidentally, bringing the contractor-engineer problem a long step toward solution. That this entrance of more and more engineers into the contracting service will benefit the individual and the profession I have no doubt. I have still less doubt of the broad practical advantages, in terms of better and more economical construction, which will result from it. In entering this field the young engineer need have no fear that his professional standing will be jeopardized. He will have plenty of opportunity to demonstrate his skill and adaptability in the emergencies that will arise, and to broaden his experience.

Finally, in any consideration of the problems confronting engineers, the overwhelming importance of engineering education cannot be forgotten. Much progress has been made in this field of recent years, especially in the recognition that a purely technical training does not necessarily produce good engineers. Our engineering schools must impress upon their students—as many of them are doing already—the realization that when they leave college for the field they still have much to learn before they are really competent to take charge of work and to attain a true professional standing. No one ever learned the important qualities of diplomacy, common sense, and an understanding of men from purely technical courses—nor, indeed, from any other set course. But the wise educator can do much to further and encourage their development in the young engineer and hence broaden his usefulness to society.

I have sought in these remarks to touch upon some of the questions which deeply concern civil engineers at the moment. It must be confessed that the immediate outlook is not one to cheer the beholder. But that holds true not of engineering alone but of almost every field of activity. And unless we choose to share in the general discouragement, I see no reason for pessimism over the future of engineering. It is absurd to think of engineering as a decadent profession; in so vigorous a profession it is equally absurd to suppose that men of ability will not presently find congenial employment according to their talents. The high conception of professional responsibility which is held by engineers, combined with the indispensability of their services to our civilization, makes this inevitable. Although in the meantime we are beset by problems both personal and professional—problems which seem not easy of solution—we may assure ourselves that they will presently be solved.

MEMOIRS OF DECEASED MEMBERS

HOWARD ADAMS CARSON, Hon. M. Am. Soc. C. E.[1]

DIED OCTOBER 26, 1931

Howard Adams Carson, the son of Daniel B. and Mary (Pope) Carson, was born in Westfield, Mass., on November 28, 1842.

He first attended the public schools in Westfield, and from 1855 to 1861, his education was continued in the schools of North Oxford and Oxford, Mass. At the outbreak of the Civil War, he enlisted in the United States Corps of Engineers and served until 1864. At the end of the war he entered the Massachusetts Institute of Technology, from which he was graduated in the Class of 1869, with the degree of Bachelor of Science in Civil Engineering.

Immediately after his graduation, Mr. Carson began work with Shedd and Sawyer, Civil Engineers, in Boston, Mass. In 1870, he became an Assistant Engineer with the Brady's Bend Iron Company, at Weston, Pa. From 1871 to 1873 he was Assistant Engineer with the Providence (R. I.), Water-Works, and from 1873 to 1877 he served as Engineer in Charge of construction of sewers in Providence. He spent the winter of 1877–1878 in Europe studying sewerage systems.

From 1878 to 1884, Mr. Carson was Principal Superintendent of Construction of the Boston Main Drainage System. He invented the Carson trench machine which was used in the construction of this work, and he was afterward President of the Carson Trench Machine Company which built trench machines that were used extensively throughout the United States. From 1884 to 1887, he was engaged in general engineering practice. In 1887 and 1888 he designed for the State of Massachusetts the Metropolitan and the Charles River Valley systems of sewerage for about twenty cities and towns. In 1889, he was appointed Chief Engineer for the Metropolitan Sewerage Commission, which position he retained until 1894 when he was appointed Chief Engineer for the Boston Transit Commission.

In 1895, Mr. Carson toured Europe for the study of engineering works of interest in Italy, Austria, Hungary, Germany, France, and Great Britain. These are referred to by him in the First and the Second Annual Reports of the Boston Transit Commission. Mr. Carson designed and had charge of the construction of the Tremont Street Subway, which was the first subway for electric cars constructed in the United States; the East Boston Tunnel, which was the first under-water tunnel for car service in this country; and the Washington Street Tunnel. He designed and began the construction of a part of the tunnel under Beacon Hill for connection with the Cambridge Subway. In 1909, he resigned his position as Chief Engineer of the Boston Transit Commission.

Mr. Carson was Consulting Engineer on works in various parts of the United States, among which were the double-track railroad tunnel under the Detroit River and some of the early studies for the New York, N. Y., and the Philadelphia, Pa., subways. He contributed a long article on "Tunnels" for the Encyclopedia Britannica.

---

[1] Memoir prepared by Wilbur W. Davis and Thomas F. Sullivan, Members, Am. Soc. C. E., assisted by Edmund S. Davis, M. Boston Soc. of Civ. Engrs.

He was an Honorary Member and a Past-President of the Boston Society of Civil Engineers, and a member of the Institution of Civil Engineers, of London, England.

He was a life member of the Corporation of the Massachusetts Institute of Technology and the oldest in point of service, having served as a Trustee since 1880. He also was a Past-President of the Alumni Association. In 1906, he received the honorary degree of Master of Arts from Harvard University.

Mr. Carson was married to Nancy Wilmarth, of Oxford, Mass., on January 17, 1870. Mrs. Carson died in 1913.

No finer tribute could be paid to an engineer than to quote the following official statement entered on the records of the Boston Transit Commission when Mr. Carson submitted his resignation as Chief Engineer in 1909:

> "In accepting the resignation of Howard Adams Carson after a service of fifteen years as its Chief Engineer, the Boston Transit Commission places upon its records this expression of the great regret which it feels at his retirement from this position and of its high appreciation of the value of the work which he has performed for the public.
>
> "The Tremont street subway, the first for electric street car service constructed in this country, the East Boston tunnel, the first sub-marine tunnel built in this country for such service, and the Washington Street tunnel, stand as monuments to his engineering skill and judgment in the solving of difficult problems. The building of these great works, through narrow and crooked streets bordered by high buildings, through filled-in ground, or below the water level, has been a difficult achievement crowned with entire success. The record which he has made in the planning and execution of these novel and hazardous undertakings has placed him in the front rank of civil engineers.
>
> "Other qualities than those of technical skill have been shown by him in an equally notable degree. His tact in dealing with public and private interests, which in the progress of these works were of necessity seriously affected, his painstaking fairness in his relations with contractors, his skill in organizing and directing the engineering staff, his executive force, and his unflinching willingness to bear every proper responsibility of his office, have all been conspicuous. Scrupulous honesty and impartiality, moderation and modesty in all things, faithfulness to the point of extreme self-sacrifice have been characteristic of his service. At the termination of that service this Commission records its admiration of his professional skill and its high regard for his personal character."

He had been in ill health for several years before his death on October 26, 1931, and, consequently, had led a retired life during that time. The funeral services were held at his home on October 29, and burial was in the family lot at Woodlawn Cemetery in Malden, Mass. He is survived by a brother, Walter Scott Carson, of Greenfield, Mass.

Mr. Carson was elected a Member of the American Society of Civil Engineers on February 7, 1894, and an Honorary Member on October 10, 1921.

RAYMOND EDMOND ADAMS, M. Am. Soc. C. E.[1]

Died December 1, 1931

Raymond Edmond Adams, the son of Joseph Reed and Eliza Ann (Wescoat) Adams, was born at Hammonton, N. J., on May 26, 1874. He attended the public schools in Hammonton and in Philadelphia, Pa., and after graduation from the Philadelphia High School, and prior to 1898, gained considerable technical experience with various engineering concerns in Philadelphia and at Dauphin, Pa. During the Spanish-American War, he enlisted in the Corps of Engineers, United States Army, serving from May to December, 1898.

In 1899, Mr. Adams was employed in the Quartermaster General's Office, U. S. Army, at Washington, D. C., and served as Assistant Civil Engineer from 1902 to 1904 and as Civil Engineer from 1904 to 1917, his work pertaining principally to hydraulics and sanitation. While in this service, he enrolled in the Engineering Course at George Washington University, receiving the degree of Bachelor of Science in 1908 and that of Civil Engineer in 1909.

In May, 1917, Mr. Adams was commissioned a Captain in the Regular Army and served on the Quartermaster Corps Staff at the Headquarters of the Southeastern Department at Charleston, S. C., until injured in February, 1918. He was discharged from the Service in February, 1919, due to incapacitation as a result of his injuries. In 1919, he enrolled as a Vocational Training Student in the Wharton School of Finance, University of Pennsylvania, and was granted the degree of Bachelor of Science in Economics in 1921.

During 1921 and 1922, Captain Adams was a Resident Auditor for the Income Tax Unit, Washington, D. C., being advanced to Assistant Valuation Engineer in 1923, and Appraisal Engineer of the Engineering Division in 1924. From 1924 until his death he was Assistant to the Engineer in Charge of Civil Engineering, Hydraulics, and Sanitation in the Construction Division of the Quartermaster General's Office, in Washington.

As a young man, Captain Adams was intensely interested in athletics and was a bicycle rider of note during his residence in Philadelphia. He later became a devoteé of chess and checkers, and was President of the University of Pennsylvania Chess Club (undergraduate) during his studies there in 1919 and 1921. He was outstanding in his professional life as an advocate of high ideals in professional ethics, was painstaking in his work, and delighted in solving the abstruse and difficult problems encountered therein. Due to his long experience in engineering work relating to the Quartermaster Corps of the Army, he was a particularly valuable assistant.

Captain Adams was active in the United Spanish War Veterans, was a Charter Member of the Washington Society of Engineers, and also a member of the American Society of Political and Social Science.

---

[1] Memoir prepared by A. L. Anderson, M. Am. Soc. C. E.

He was a Mason, being affiliated with Olivet Lodge No. 607, Philadelphia, and Mount Horeb Chapter No. 9, Washington, D. C. He was a Protestant by faith and, although not affiliated with any church, was a splendid example of the true Christian, in that he inherently was possessed of a high standard of moral and social ethics, ordered his life in accordance therewith, and reflected this spirit by the kindly and generous manner he showed to all with whom he came in contact.

He is survived by his widow, Eleanore Hoffman Fletcher, whom he married in 1899, at Philadelphia, and by three children—two sons, Raymond Fletcher and Nellson Reed, and a daughter, Jessica (Adams) Lovewell.

Captain Adams was elected a Junior of the American Society of Civil Engineers on May 1, 1900; an Associate Member on December 6, 1905; and a Member on May 28, 1912.

WILLIAM GEORGE ADDIS, M. Am. Soc. C. E.[1]

Died December 17, 1931

William George Addis was born in Bristol, England, on May 6, 1862. His parents, Edwin J. and Elizabeth (Dimmer) Addis, were of English and Welsh descent. In 1870, the family, consisting of the parents, William, and a younger brother and sister, emigrated to the United States and settled first at Amherst, Mass., where the father began to practice his trade of cabinet maker, and where one more child was born to the family. The move to this country was probably influenced by the fact that two brothers of the elder Addis had previously come and were established in New Jersey and New York. Formal collegiate education was out of the question in this family, and as the oldest of four children, it was necessary for William George Addis to go to work in 1878, upon the completion of his public school education in Northampton, Mass. He was able, however, to follow a course of study and training in Civil and Mechanical Engineering privately under tutors, and for seven years found employment which afforded practical experience in these lines near home.

His active career in the practice of engineering began in 1885, and until his death, on December 17, 1931, Mr. Addis continued in engineering work. During this period he held many positions in his chosen profession which covered a wide field. The first eight years of practice were along mechanical lines. For five years he was Assistant Engineer on steam vessels on the Great Lakes and along the Atlantic Coast. From 1890 to 1893, he held the position of Construction Engineer with the Overman Wheel Company, of Chicopee Falls, Mass., and was in charge of the installation of power plants. From 1893 to 1901, he carried on a private consulting practice, and from 1901 to 1903, he was Chief Inspector of Reservoir Construction for the City of Northampton. In 1903, he was connected with the Metropolitan Water Board of Massachusetts as Inspector of Concrete Masonry in water tunnels.

---

[1] Memoir prepared by F. C. Pillsbury, M. Am. Soc. C. E.

For three years, from 1904 to 1907, Mr. Addis was Resident Engineer with the Massachusetts Highway Commission, in charge of construction. From 1907 to 1909, he held the positions of Designing Engineer and Superintendent of Construction with the R. B. Carter Company, of New York, N. Y., Water Supply Engineers and Contractors. From 1909 until his death, Mr. Addis was connected with the Highway Commission of Massachusetts (which, later, became incorporated in the Department of Public Works), except during 1918 when he was Inspector of Materials for the Construction Division, United States Army, at the Pittsburgh, Pa., District Office. During his connection with the State of Massachusetts, he served, successively, as Resident Engineer in charge of highway construction, as Survey Chief of Party, and as Assistant Engineer in charge of estimating.

Mr. Addis was deeply interested in the problems of the younger men in the profession. His cheerful philosophy, his keen sympathy and understanding, and his words of good advice, were ever a source of encouragement to those with whom he had contact, and his exemplification of living—of optimism—an inspiration. He was very fond of flowers; their cultivation was his hobby, and his brilliant garden annually was evidence of the success of his efforts in this direction. Throughout his life he had always been very active, but a serious illness in July, 1930, confined him to his home in Winthrop, Mass., for several months. In the spring of 1931 he was able to resume the duties of his employment, but early in December there was a recurrence of his illness, from which he never recovered.

Mr. Addis was a member of the American Association of Engineers, in which Association he had held the office of National Director for the New England District from 1927 to 1929, and in which, also, he was President of the Boston Chapter at the time of his death. He was affiliated with several Masonic bodies in the Connecticut Valley, including Jerusalem Lodge, A. F. and A. M., of Northampton, Northampton Royal Arch Chapter, Northampton Commandery, Knights Templars, and Melba Temple, A. A. O. N. M. S., of Springfield, Mass. He was also a member of the Canopy Club, of Boston, Mass.

He was married in September, 1893, to Anna H. Strong, of Glastonbury, Conn., who survives him. He leaves also a brother and other relatives both in this country and in England.

Mr. Addis was elected a Member of the American Society of Civil Engineers, on September 2, 1914. He was also a member of the Northeastern Section of the Society.

WILLIAM HENRY ADEY, M. Am. Soc. C. E.[1]

DIED MAY 17, 1930

William Henry Adey, the son of George and Katherine E. (MacNivin) Adey, was born in Cohoes, N. Y., on December 6, 1872, of English and Scotch ancestry. He was an alumnus of Rensselaer Polytechnic Institute, Troy, N. Y., from which he was graduated with the degree of Civil Engineer in 1895. He was a member of the Sigma Xi and Theta Nu Epsilon Fraternities.

---

[1] Memoir prepared by Dwight B. LaDu, M. Am. Soc. C. E.

After his graduation, Mr. Adey was employed on the construction of the Troy and New England Railroad and assigned as Inspector of pile-driving and pile trestles. He was also engaged for several years with Henry B. Seaman, M. Am. Soc. C. E., in land development work in Staten Island, New York, and, later, became identified with teaching his chosen profession at Swarthmore College, near Philadelphia, Pa. During several months of 1898, because of the disability of the Head of the Department, Mr. Adey was placed in complete charge of the Engineering Department. From May until November, 1898, he had charge, for the Dunsbach's Ferry Bridge Company, of the construction of a three-span pin-connected bridge, with a total length of 612 ft., across the Mohawk River, at Dunsbach's Ferry, N. Y.

In March, 1899, Mr. Adey accepted a position with the Engineering Forces of the Delaware and Hudson Railroad Company. He served in various grades, successively, from Rodman to that of Office Engineer, which position he held at the time of his death. During this period, he was engaged in preliminary surveys and surveys for improvements. Under the direction of the Chief Engineer, he designed coal-transfer trestles, a number of under and overcrossings, and was placed in charge of their erection.

As an Engineer, Mr. Adey was deeply interested in his profession and was esteemed by his associates. He was also interested in community affairs and was a member of the Masonic fraternity, the Young Men's Christian Association, the Albany Society of Civil Engineers, the National Geographic Society, and the Delaware and Hudson Veterans Association. He was a member of the Reformed Church of America.

He was married, in Cohoes, on May 1, 1902, to Myra Hermans Van Olinda. They had two children, Myra Harriet and Marion Elizabeth.

Mr. Adey was elected a Junior of the American Society of Civil Engineers on February 4, 1896; an Associate Member on December 3, 1902; and a Member on May 8, 1922.

ANDREWS ALLEN, M. Am. Soc. C. E.[1]

Died March 21, 1931

Andrews Allen was born at Madison, Wis., on January 11, 1870, the son of William Francis and Margaret (Andrews) Allen. His father was a direct descendant of James Allen, of Dedham, Mass. (1639), and his mother, of Thomas Andrews, of Hingham, Mass. (1642).

He attended the public and High Schools at Madison and entered the University of Wisconsin in 1887, from which he was graduated with the degree of Bachelor of Science in Civil Engineering, with honors, in 1891. In 1894, the University conferred upon him the degree of Civil Engineer, his thesis being "The Complete Design of a Railroad Swing Span, Including Steel Work, Machinery, and Power Plant." He was a member of Beta Theta Pi Fraternity and the Honorary Engineering Society, Tau Beta Pi.

---

[1] Memoir prepared by Joint Committee of the Society and of the Western Society of Engineers, consisting of C. W. Gennet, Jr., and A. J. Hammond, Members, Am. Soc. C. E., and C. W. Brooks, M. W. S. E.

Andrews Allen's early engineering training and experience was obtained with the Chicago and Northwestern Railway Company as Rodman, and as Assistant Engineer on city and county work in the vicinity of Madison, during vacation periods. After his graduation from college, he served with Professor Charles M. Van Hise, as Geologist for the United States Government Survey in Northern Michigan.

In the fall of 1891, he entered the employ of the Edgemoor Bridge Works, at Wilmington, Del., serving in the capacity of Draftsman, Assistant Engineer, and Designer. While he was at Wilmington he designed many railroad structures, including the Queen and Crescent Bridge over the Cumberland River, the Chicago, Lake Shore and Eastern Railway Company's swing span over the Calumet River, and a swing span for the City of Norfolk, Va.

In 1899, Mr. Allen became associated with the Wisconsin Bridge and Iron Company, of Milwaukee, Wis., as Contracting Engineer in charge of the Chicago Office. His work with this Company covered designing and contracting for steel structures of all kinds, including railroad and highway bridges and industrial and mining buildings. Some of the more notable structures designed under his supervision at this time included the Paoli Viaduct for the Monon Railroad Company, the Kankakee River Bridge for the Wabash Railroad Company, swing spans for the Chicago Junction Railway, and the Indiana, Illinois, and Iowa Railroad Companies, and the International Bridge, at Brownsville, Tex.

Mr. Allen was a specialist in the design of swing spans, and was frequently consulted by engineers where structures of this character were contemplated. The commercial side of his work, however, was not as interesting to him as the purely technical. Possessed of a keen scientific mind, and a thorough knowledge of mathematics and mechanics, he was always interested in developing a theoretically perfect structure. He developed the A-frame type of tower for coal mines, the three-column head-frame, and a special self-dumping cage for mining towers.

His desire for consulting work only, resulted in the formation, in 1911, of the Allen and Garcia Company, Consulting and Constructing Engineers. This Company, of which Mr. Allen was President, specialized in the design and construction of coal-mining plants throughout the United States. The Company was eminently successful, and, at the time of Mr. Allen's death, the members were Consulting Engineers for the Soviet Government in the development of its coal resources.

Mr. Allen was a non-tiring worker; on becoming absorbed in an engineering problem, he would labor from 16 to 18 hours a day until the task was completed. He frequently wore out his assistants, who were not able to bring the same energy and enthusiasm to their work that he always displayed.

He was Special Lecturer at Northwestern University on engineering subjects; Chairman of the Illinois State Board of Examiners for Structural Engineers; President (in 1909) of the Western Society of Engineers, and recipient of the Chanute Medal in 1916 for a paper on "The Engineering Opportunities of Our Coal Mining Fields".[2] He also contributed many articles to the technical magazines, as well as papers before the American Institute of Mining and Metallurgical Engineers and the Western Society of Engineers.

He was a member of the American Institute of Mining and Metallurgical Engineers, the American Railway Engineering Association, the Kentucky Mining Institute, the Chicago Engineers Club, the Western Society of Engineers, the Union League Club of Chicago, the Theosophical Society, the Wisconsin Society of Chicago, and the Masonic Orders, including Chapter, Commandery, and Shrine.

Andrews Allen was a rare character, loved by those who knew him for his great personal charm and willingness to help all those with whom he came in contact. He was universally admired for his engineering skill and attainments. He was a natural born teacher, and would work countless nights with the younger engineers, including many outside his employ, explaining mathematical and mechanical problems, expressing keen delight when the results of his teaching became apparent. He found his recreation in his great love of the out-of-doors, fishing, golf, and frequent camping trips to the Rocky Mountains. In the passing of Mr. Allen, the Engineering Profession has lost one of its most brilliant members, and the younger engineers a friend and counselor.

He was married, in 1916, to Elizabeth Emerson Cooke who, with four children, Francis, Henry, Andrews Jr., and Katherine, survives him.

Mr. Allen was elected a Member of the American Society of Civil Engineers on October 4, 1905.

LOUIS RUSSELL ASH, M. Am. Soc. C. E.[1]

DIED APRIL 7, 1930

Louis Russell Ash was born near Uniontown, Ky., on September 27, 1873. After completing his public school education, he attended the University of Arkansas and was graduated with the degrees of Bachelor of Civil Engineering in 1893 and Bachelor of Electrical Engineering in 1894. During his college years he had practical experience working in his father's saw-mills. With the early death of his father, he assumed with characteristic unselfishness the responsibilities of an eldest son in a large family—responsibilities which continued throughout his life. In 1895, he was called to the Chair of Mathematics in Coe College, Cedar Rapids, Iowa, where he taught for six years. During the summer vacations he was actively engaged in engineering work. He also attended the University of Chicago for special courses during one or two summers.

---

[2] *Journal*, Western Soc. of Engrs., Vol. XIX, May, 1914, p. 413.

[1] Memoir prepared by E. E. Howard and Henry C. Tammen, Members, Am. Soc. C. E.

Mr. Ash's active engineering work began in June, 1901, when he joined the staff of Waddell and Hedrick, Consulting Engineers, Kansas City, Mo., specialists in bridge design. His work was principally in the office in detailing and design work until he became Chief Draftsman, in which capacity he continued until the dissolution of that firm.

In January, 1907, Mr. Ash formed a partnership with Ira G. Hedrick, M. Am. Soc. C. E., as Consulting Engineers, and practiced for some years. Principal among the structures he designed during this period was the Oak Cliff Viaduct, at Dallas, Tex., a notable reinforced concrete viaduct of the arch type across the Valley of the Trinity River.

In 1910, Mr. Ash was made City Engineer of Kansas City, Mo., and began a notable service for that city which made him widely known and greatly respected, not only for his obvious ability as an engineer, but for his complete candor, open honesty, and unusual fairness. His character did not change; people merely came to know him until practically every one in the city knew him or knew of him and regarded him with both respect and affection which continued to the time of his death.

As City Engineer, Mr. Ash not only directed current work, but formulated extensive general plans for trafficways, and comprehensive sewerage and waterworks systems, many of which have since been carried out by others. He laid out and constructed the McGee Street Trafficway, one of the most heavily traveled thoroughfares of the city. He made a complete valuation of the Street Railways' properties. He had a principal part in the solution of the complex problems of trafficways into the low-lying Kaw Valley District which resulted in the construction of the Twelfth Street Viaduct and, later, the Twenty-third Street Viaduct. He evolved what came to be known as the Ash Plan for flood protection, and devised the Turkey Creek Tunnel diversion scheme. A change of administration after two years did not bring the customary and expected change of engineers, and Mr. Ash's services came to be so highly regarded that when he proposed to accept a more lucrative position, the Mayor increased his salary to an amount greater than that which he himself was receiving.

In 1913, however, Mr. Ash resigned from his municipal work and returned to private practice as a Principal Assistant Engineer of the consulting engineering firm of Waddell and Harrington. That firm was later dissolved, and Mr. Ash joined in forming the consulting engineering firm of Harrington, Howard, and Ash. He continued as a member of this concern until its dissolution in 1928, and then became a member of the firm of Ash-Howard-Needles and Tammen, carrying on a similar work. He continued with this firm until his death on April 7, 1930.

During this entire period Mr. Ash was very active in civic affairs in Kansas City. He served on two Charter Commissions and was active in promoting the present City Manager form of City Charter. He was a member of the first City Plan Commission and served thereon for several years.

His prominence in all efforts for civic betterment was so widely recognized not only in Kansas City, but in adjacent cities, that when, in 1917, Wichita, Kans., adopted the City Manager form of government, at that time the largest city that had yet turned to that plan, the municipal authorities impressed Mr. Ash into their service. Mr. Ash arranged a leave of absence with his firm in the summer of 1917 and served as City Manager of Wichita for about two and one-half years. This had exceeded his promised stay and he felt that he had demonstrated the merit and efficiency of the plan and had organized city affairs on a sound and business-like basis. Leaving a new host of friends and well wishers, and with testimonials of his successful administration, he returned to Kansas City late in 1919 and resumed practice with his firm.

He took a very active part in the work of all the firms with which he was connected, which covered the engineering of large bridges in many parts of the United States as well as abroad. Included were such structures as the Dumbarton Bridge across San Francisco Bay, the bridge across Mobile Bay, bridges across the Columbia, the Willamette, the Fraser, the Colorado, the Missouri, the Ohio, the St. Johns, the Hudson, the Arkansas, the White, the Mississippi, and other rivers, and many viaducts and similar structures. To this work Mr. Ash brought not only a sound technical ability and intense energy, but an unusual fair-mindedness in administration.

He had that rare sort of honesty that ignored entirely what might have been his personal interest or any thought of the effect of a decision on himself, and he had a fairness that could always see the viewpoint of the other man. These characteristics were so generally recognized and respected that he was frequently called upon for that trying task of acting as arbitrator in disputes between engineers, owners, and contractors.

The bridge at Vicksburg, Miss., which is the farthest down stream and probably the largest bridge yet constructed across the Mississippi River, was in a special way Mr. Ash's personal task and personal accomplishment. It was completed and opened to traffic only a few weeks after his death. He gave to it his closest attention—from the direction of the investigation of foundation conditions to substantial completion. He determined the location, projected the connecting railways and highways, directed the design, wrote the specifications, and gave personal supervision to the construction. His associates have felt that his intense fidelity to this work contributed to his early death. In the late fall of 1929 Mr. Ash visited the work to make a final decision on the foundation of one of the deep pneumatic piers. In spite of warnings from his doctor of a weak heart condition and high blood pressure, and contrary to other counsel, he felt so intensely his responsibility that he insisted on going himself into the deep working chamber under heavy air pressure, and there suffered a partial collapse. The owners are arranging for the erection of a memorial to Mr. Ash near the end of the bridge, comprising a stone with a memorial tablet and a bronze bas-relief portrait of him. From the sightly high hills of Vicksburg, this will overlook the bridge, his last great work.

His death came very unexpectedly and in the midst of activities. During March, 1930, he had a slight heart attack while on an inspection trip at Yankton, S. Dak., which incapacitated him for a day or two. On his return to Kansas City he pursued his usual work and was undergoing a complete clinical examination by his doctors and contemplating a considerable period for rest and recuperation. However, on April 6, 1930, during a Sunday of usual activity at church and at home, another heart attack occurred and Mr. Ash passed away on Monday morning, April 7, 1930.

Mr. Ash was a Member of the American Society of Municipal Improvements; Past-President of the Engineers Club of Kansas City; Past-President of the City Club of Kansas City; a member of Tau Beta Pi; a Mason; and was identified with other organizations. In addition to his professional work and civic and club activities, he was for many years active in the Linwood Presbyterian Church, serving as an officer in various capacities. He was also a Trustee of Park College.

His fellow engineers have expressed the opinion that there is no one left to occupy the unique place he held in Kansas City, and that the confidence of the people in him has reflected to the benefit of the entire Engineering Profession.

Mr. Ash was married in 1905 to Hadgie B. Davies, of Fayetteville, Ark., who, with one son, Samuel, survives him.

The *Kansas City Star* commented editorially as follows:

"Louis R. Ash was a type of citizen that every city needs. His profession of engineering may have had something to do with his high regard for system, efficiency, and order and with his intolerance toward things haphazard, including city government. He was assertively public-spirited. He recognized the obstructive effect of pernicious partisanship in city affairs. He helped to procure the adoption of the new charter after he had helped to frame it.

"Every genuine movement for municipal progress had his support. Some have been successful and some have failed, but Mr. Ash never lost his zeal for better standards of government. It was with better government as his objective that he led the recent non-partisan government movement before the city campaign. When, some years ago, he asked for leave of absence from his firm to accept the city managership of Wichita, the change must have involved some professional and business sacrifice, but he hoped to demonstrate the merits of the newer form of government.

"Mr. Ash was only 56. Actuated as he was by progressive, public-spirited ideas, he would have continued his efforts had he lived. In his death the city loses an individual factor in courageous civic effort. Even those who disagreed with him or lacked his faith in ultimate accomplishment, acknowledged his sincerity and respected his motives."

From *Engineering News-Record* is taken the following tribute:

"AN ENGINEER'S PUBLIC SERVICE"

"The quality of our municipal governments depends upon the collective efforts of the individual. It is good or poor depending upon whether the majority of those who direct its affairs are well trained or are uneducated in such matters.

"Civil engineers by their training are peculiarly fitted to advise cities upon many municipal matters and to take part in the direction of city affairs. But few of them do. Too many sit by and decry the fact that their qualifications in that respect are unappreciated. In this the fault lies with them rather than with the public; if they are to be appreciated they must take the initiative and so let the public know what they can do.

"The late Louis R. Ash was a splendid example of how effective engineers can become in municipal affairs if they make it their business to take more than a passive interest in civic problems. Of him, the *Kansas City Star* commented at the time of his death:

" 'This country needs more such engineers. They may not be right at all times; they are sure to be misunderstood and abused frequently; but in the long run they will make an impression that will be felt and will be appreciated as Mr. Ash's service to Kansas City is appreciated.' "

Mr. Ash was elected an Associate Member of the American Society of Civil Engineers on December 5, 1906, and a Member on September 6, 1910.

PETER CHRISTIAN ASSERSON, M. Am. Soc. C. E.[1]

DIED DECEMBER 6, 1906

Peter Christian Asserson was born on the Island of Egersund, off the southwest coast of Norway, on January 5, 1839, the youngest of a family of twelve children. His forebears, as well as his own generation, were rugged Norse folk as evidenced by the family records which show that his paternal grandparents, his maternal grandmother, and his own mother reached the advanced ages of 100 years and more (the paternal grandmother, 104 years), and four of his own sisters and one brother were well over 90 years of age when they died.

His mother and father were staunch members of the Evangelical Lutheran Church and were deeply religious. He refers to them in writing as "my sainted mother and father to whose early teachings, precepts, and worthy example is due the little success that I may have been able to obtain in life." Although his father served as a Lieutenant in the Coast Guard from 1812 to 1814, at the time of the separation of Norway and Denmark, his real occupation was that of a farmer.

Peter Christian Asserson obtained his elementary education in the public schools of his district, and had his first engineering experience at the early age of 16 years, when he was employed as Second Assistant Engineer on the erection of a stone tower lighthouse built on an isolated and rocky promontory on Egersund's Island, about two miles from his father's farm. Toward the end of this year, however, an overpowering desire to follow the sea, so strong in the Scandinavian race, took possession of the lad and he shipped as cabin boy on a bark sailing from Stavanger, a near-by port, to the Mediterranean and Black Seas.

The following four years, from 1855 to 1859, were spent at sea, where he served as Second and First Officer and, finally, as Captain of merchant ships sailing from English, German, and Scandinavian ports. In 1859, at the age of 20 years, Mr. Asserson came to America with his mind made up to establish himself in this country. Soon after his arrival he obtained an appointment to the United States Coast Survey and Lighthouse Service. He first assignment was to the Gulf of Mexico where he was engaged on a hydrographic survey of the Gulf and where he also assisted in the erection of a large screw-pile lighthouse—"Shoal Light"—fifteen miles from shore, the first high-power lighthouse ever erected on a shoal in the ocean so far from the mainland.

---

[1] Memoir prepared from information on file at the Headquarters of the Society.

It was Mr. Asserson's intention to follow eventually the example of many of his Scandinavian compatriots, and as soon as circumstances and funds would permit, to make his way up the Mississippi River and to establish himself in the Middle West. Fate, however, dictated otherwise. When the storm, then hovering over the United States, broke on the morning of April 12, 1861, Mr. Asserson was faced with the alternative of making a hasty departure from the South or of acceding to the wishes and following the example of his friend and associate, Lieut. Joseph Fry, of Louisiana, by signing up for service with the Confederacy. As Mr. Asserson's sympathies were with the North, he was compelled to make a hasty departure from New Orleans, La., which he did by offering to take a merchant ship, which was loaded only in the afterhold, to her consignees in Spain. There was no time to shift the load so he ran the blockade which was already established in Southern waters, and, at great risk, due to the unequal ballast, set sail for Spain, where he safely delivered the ship and cargo.

As he had firmly made up his mind to become an American citizen, Mr. Asserson returned at once to this country and made preparations to fit himself for service in the United States Navy by taking special courses in engineering, navigation, and astronomy at Cooper Union, in New York City. He received instruction also under private tutors. It is of interest to note that he, with five other young men seeking Naval commissions, made up a class in navigation which was taught by the widow of a sea captain, Mrs. Thom, who had accompanied her husband for many years on his sea trips and who often assisted him in navigating his ship.

Mr. Asserson's industry and efforts were finally rewarded for he passed his examinations successfully and in May, 1862, received his appointment to the United States Navy with the rank of Master's Mate. He, thereafter, participated in many of the important naval campaigns of the Civil War. As Master's Mate he served throughout 1862 on the U. S. Ships *Relief, Vixen, Patroon,* and *Wamsutta,* on blockading duty. Toward the end of that year, November 24, 1862, he was promoted to the rank of Ensign and was given command of the *Zouave,* later, the *Cohasset, Shockokon,* and *Berberry.* In June, 1865, he was ordered to take the *Berberry* from Beaufort, S. C., to Hampton Roads, Va. On his departure, the Commanding Officer of the Station, Lt. Comdr. William C. West, wrote "your vessel has been ordered north—in parting with you I must express my appreciation of the ability and zeal you have shown in the performance of your duties while under my command. Wishing you every success in life, I am truly your friend." After this, Mr. Asserson served on the U. S. S. *Florida,* as Navigator and Division Officer. He participated in the attacks on Fort Fisher, Pocataligo Bridge, South Carolina; Castle Thunder, near Savannah, Ga.; Bermuda Hundred, Petersburg, Turkey Bend, and Drury's Bluff, in the James and Rappahannock Rivers. In these engagements he served under Rear-Admirals David D. Porter, S. F. Dupont, Hiram Paulding, and C. R. P. Rodgers. To the latter, Mr. Asserson was ever grateful for the encouragement and assistance he gave at a later date, toward helping him to get his appointment to the Civil Engineer Corps of the Navy.

From March, 1866, to 1868, Mr. Asserson was assigned to duty at the Norfolk (Va.) Navy Yard. From 1868 to 1869, he was on Coast Survey duty in command of the *Hasler* and, finally, in March, 1869, he was honorably discharged from the Service as a volunteer officer with the thanks of the Navy Department, which he had faithfully served from 1862 to 1869.

Mr. Asserson then became engaged in the important and difficult task of removing the obstructions and clearing the wrecks, the results of the war, from the Elizabeth, James, Rappahannock, and Potomac Rivers. He raised successfully four battleships and two frigates, besides a number of river craft, and in so doing performed some of the most difficult feats known to marine engineering. Among the wrecks removed were the famous gunboat *Merrimac,* sunk by the *Monitor* in Hampton Roads, near Crany Island; the U. S. S. *Cumberland,* sunk at Newport News, Va., the first of the Federal ships to be sunk by the *Merrimac;* the U. S. S. *Pennsylvania,* which was raised by means of a coffer-dam and towed to the dry dock at the Norfolk Navy Yard; the *Columbia;* the *Raritan;* and the U. S. S. *Delaware,* from which he secured, intact, the interesting figure-head of the famous Indian Chief, Tecumseh, and which, later (in the early Seventies), he presented to the U. S. Naval Academy where it was placed on a pedestal in the grounds of the Academy. Further honors were bestowed upon him (the old Chief) by the young midshipmen who dubbed him the "God of 2.5" (the passing mark in their studies), and who never fail to implore his favor before going up for their examinations. In recent years the picturesque old wooden figure which was painted to represent the regalia of an Indian chief, has been transferred to the Museum for preservation and has been replaced by a replica in bronze, which is still known as the "God of 2.5," and still receives the supplications of the midshipmen.

In June, 1871, Mr. Asserson received his final naturalization papers and thus became a citizen of the United States. In April, 1873, he was appointed Superintendent of Improvements at the Norfolk Navy Yard and Assistant in charge of the reconstruction work of that Yard, which, at the close of the conflict in 1865, was practically in ruins—the machine shops and office buildings had been burned to the ground, the dry dock blown up, and the gates and caissons destroyed.

In March, 1874, in President Grant's Administration, Mr. Asserson successfully passed his examinations and was commissioned a Civil Engineer in the U. S. Navy. He was at once placed in full charge of the reconstruction work already begun at the Norfolk Yard and within a period of ten years this station was practically transformed. Long stretches of substantially built wharves and quays replaced the old wooden ones; the dry dock was rebuilt; wet docks were built to receive timber needed for the ships of that date; and workshops and storehouses that covered many acres of ground were erected. The streets were well paved, and up-to-date sewerage and drainage systems were constructed. One of Mr. Asserson's outstanding accomplishments at this time was the installation of a salt-water fire system, the first in this country, and said at that time to be one of the most practical features introduced in any Navy Yard. By a unique automatic contrivance heavy pressure was carried on the salt-water mains only when needed.

In 1882, Mr. Asserson was promoted to the rank of Captain. This promotion, and similar promotions for other members of the Corps, came as a result of a long and vigorous campaign by him and his colleagues to have the same privileges of promotion and rank which the officers of the line and others of the staff were accorded. In 1885, Captain Asserson received due recognition for his outstanding accomplishments at the Norfolk Yard and was ordered by the Department to duty at the larger and more important naval station in New York, where he continued with indomitable industry to make that station one of the best equipped in the country. When he began his tour of duty the Yard was practically without a dry dock or wharf at which a ship could be tied up. There was only 15 ft. of water in the Wallabout Channel, the "cob dock" and ordnance docks were being eaten away by East River tides, many of the streets were unpaved, and the big granite Dry Dock No. 1 was leaking.

His first task was to save portions of the "cob dock" by building substantial sea walls in place of the old wooden ones. The new wall was 2 230 ft. long, built over solid cribwork of Georgia pine (2 by 12 in.), on which was laid a superstructure of concrete—the whole being capped with a coping of granite blocks. This piece of work was examined by experienced engineers who reported that there was not another like it in the United States. Here, again, he installed a salt-water fire system, as well as automatic sprinkler systems in the buildings; erected several new buildings, among them a mammoth machine shop; several miles of railroad; a new electric light and power plant; an immense coaling pier and coal-pockets to accommodate from 10 000 000 to 15 000 000 tons of coal. Dry Docks Nos. 1 and 2 were rebuilt of concrete. This was considered a triumph as they were designed, reconstructed, and enlarged without the help of outside contractors. For the former he built an underground electric pumping station, at that time the only one of its kind on record. This was constructed so as to save space and was located at the head of the dock, built entirely beneath the surface, encased within a caisson or wall of cement or stone, thus insuring the machinery against damage by cold, heat, or moisture. Centrifugal pumps were installed with a capacity of throwing 30 000 gal. of water per min. out of the dry dock, thus enabling the dock to be completely emptied of water in one-third the time and at one-half the cost of the former method. This also attracted much attention in the engineering world. Dry Dock No. 3 was built under his supervision and plans were made for Dry Dock No. 4, the latter, however, was not undertaken as his retirement from the service was then about due.

As early in his career as 1882 and 1884 Captain Asserson was called to the Bureau of Yards and Docks in Washington, D. C., as Senior Member of Boards to consider plans and specifications for the dry dock at Mare Island, California, and to examine and report on pumps in connection with dry docks.

In 1883, he received a note from the Hon. William E. Chandler, then Secretary of the Navy, in which he is commended for his "skill, energy and efficient service in successfully raising and docking the sea-going tug, the *Jean Sands*."

In 1884, he was sent to St. John's, Newfoundland, to inspect a dry dock recently constructed for the Colonial Government and, a few months later, just prior to being sent to the New York Yard for permanent duty, he was ordered to examine the defective parts of the "cob dock" with a view to repairing it and to determine when and where the work of dredging near it should be done preparatory to the construction of certain timber cribs.

In 1889, Captain Asserson was appointed Senior Member of a Board for plans and specifications for a protective wall along the filled-in portion of the Delaware part of the Philadelphia, Pa., Navy Yard; in 1890, he was Senior Member of a Board for plans and specifications for the construction of a timber floating dock at Port Royal, S. C.; in 1894, Senior Member of a Board for plans and specifications for the construction of a dry dock in Puget Sound, Washington; in 1898, Member of a Board on "Location of Dry Docks"; in 1899 and 1900, Senior Member of a Board to inspect and consider certain changes in the sea wall and foundations of some of the buildings at the Naval Station in Annapolis, Md.; and, in 1900, on a board of inspection and survey of Port Royal and Charleston, S. C., for the purpose of examining the expediency of changing the location of the Naval Station from Port Royal to Charleston, or its vicinity.

His retirement from active duty was due January 5, 1901, but he served at the request of the Government, almost two years longer, and finally asked to be relieved of duty at the age of 64, as his health had become impaired. He was accordingly retired as a Rear-Admiral, the next higher grade to the one to which he had been promoted several years previously.

At the time of his retirement Rear-Admiral Asserson had made his reputation as an engineer of the highest ability. He was from the time of his appointment to his retirement senior member of the Corps of Civil Engineers, and was considered an authority on dry dock building, for which he was a Consultant at almost every Navy Yard in the country. He had a great fund of knowledge acquired largely in the school of experience and through constant reading and studying; he practically mastered the theory of his profession through his own efforts. He was an indefatigable and tireless worker and excelled as an administrator and executive in his ability to carry the important responsibilities of his department. One distinctive feature of his administration always was the moderate costs of his achievements, especially as compared with contract prices. He was always faithful to his trust and labored unceasingly for the best interests of the Government he was serving.

Loyalty to his Corps also led him and his colleagues, a small group of civil engineers, to try to break down the precedent which had been established for many years, of having a line officer in charge of the Bureau of Yards and Docks in Washington. In 1882, a petition signed by all members of the Corps was presented to Secretary Chandler, urging him in all justice and propriety to appoint a civil engineer to this important position. Finally, in 1898, success rewarded their efforts and Captain Asserson, as Senior Member and Dean of the Corps, was slated for this position, but he refused this honor as he had but two more years of service and the appointment was for four years. He believed that it would be unwise for the engineers to hold the hard-won position for so short a term, therefore, he insisted that the appointment should go to the late Rear-Admiral Moredecai T. Endicott, Past-President, Am. Soc. C. E., who received the appointment, much to the satisfaction of Captain Asserson and all the other civil engineers of the Corps.

Admiral Asserson was married in 1864, to Mary A. Wilson, a daughter of Henry and Rebekah Wilson, of Brooklyn, N. Y. Of their children, eight in number, seven were living in 1906 when he died of angina pectoris at the age of 68 years. Malena, the eldest, wife of Rear-Admiral W. B. Fletcher, U. S. N.; Henry R., a civil engineer in the Municipal Department of New York City, who served with the Engineers in France during the World War; Ane G., wife of Lt. Col. William F. Spicer, U. S. Marine Corps; M. Alice, a physician on the Medical Staff of Teachers College, Columbia University, who also spent a year in France during the World War organizing tuberculosis clinics under the auspices of the Rockefeller Commission for the Prevention of Tuberculosis in France; William C., a Captain in the U. S. Navy, who, as a young officer, took part in the Spanish- American War and who, later, in the World War, as Captain of the U. S. S. *Castine,* did patrol duty in the Mediterranean Sea; Agnes C., wife of Justin R. Swift, son of Rear-Admiral Swift, U. S. N.; and Frederick A., a surgeon in the U. S. Navy who, in the World War, was Executive Officer of the U. S. Naval Hospital in Newport, R. I., and, later, Medical Executive Officer of the U. S. S. *Leviathan* which was used to transport wounded soldiers from France to the United States. At present (1932), there are living four sons and daughters, fifteen grandchildren, six of whom were also commissioned officers in the U. S. Navy and served in the World War, and eighteen great-grandchildren.

Admiral Asserson's married life was a remarkably happy one—always a devoted, affectionate, and most unselfish husband and father. He had an inherent forcefulness and strength of character which was felt at once by all who came in contact with him, and although the practical side of his nature had been strongly developed his deeply religious and sympathetic nature was readily apparent to those who knew him best. He had a strong and rugged physique, inherited, no doubt, from his long-lived Norse ancestry, a cheerful, buoyant temperament, and a keen sense of fun and humor. He was a hard, conscientious worker, never satisfied with makeshifts or half-way measures; a favorite maxim and one which he quoted often to his children was "that which is worth doing at all, is worth doing well." He was a student and was blessed with an excellent memory. He found his greatest recreation in reading history and biographies of great men, and in his love for poetry and music. His mind was keen and alert, his vision far-seeing, his judgment good, and his ideals high. He was courageous to the point of aggressiveness if he felt it necessary to be so in upholding that which was right and just. A man, who with few opportunities and advantages in his young days, made a success of his life by cultivating the best that was in him and by giving generously of himself to the land of his adoption, his family, associates, and friends.

Admiral Asserson was elected a Member of the American Society of Civil Engineers on July 5, 1882.

FRANK HARRISON BAILEY, M. Am. Soc. C. E.[1]

Died April 29, 1931

Frank Harrison Bailey, the son of Harrison C. and Minerva L. (Stoddard) Bailey, was born in Wellsboro, Pa., on February 19, 1866. He was graduated from the Grammar School in the town of his birth, and from the High School and State Normal School of Mansfield, Pa.

Mr. Bailey was a student from the time he entered the Grammar School until his death. Graduating from High School at the age of 13, he passed the examinations to the State Normal School, but the State law would not allow his entrance until he was 16. He, therefore, returned to High School for special work until he reached the required age, when he entered the State Normal School, from which he was graduated in the spring of 1883 with the degree of Bachelor of Engineering at the age of 17.

His first work after graduation was with the Engineer Corps of the Fall Brook Railroad Company (now the Pennsylvania Division of the New York Central and Hudson River Railroad); after serving for a short time as Chainman, Rodman, and Levelman, Mr. Bailey went to Litchfield, Conn., as Transitman on a railroad locating party.

In 1885, he went to Boise, Idaho (then Boise City) where he was engaged as Transitman on location and construction work for the Union Pacific Railroad Company; in 1886, he went to Ouray, Colo., as Resident Engineer for the Denver and Rio Grande Railroad Company, and remained there until 1889 when he returned East. Shortly afterward he entered into partnership with Mr. William Rollins, then City Engineer of Elmira, N. Y. The firm carried on a general engineering and contracting business, but specialized in city improvement work, laying out and constructing additions to Elmira, as well as to many other towns in Southern New York and Northern Pennsylvania.

Early in 1895, Mr. Bailey was taken suddenly ill and for two months was not expected to survive, his partnership with Mr. Rollins in the meantime having been dissolved. It was not until the spring of 1896 that he was able to resume work, and he then took the position as Engineer for the New Orange Industrial Association, laid out and improved the town site of

---

[1] Memoir prepared by Ralph J. Bailey, Civ. Engr., Portland, Ore.

New Orange, N. J., and built a railroad connection from that place to the Central Railroad of New Jersey, at Roselle, N. J.

This work was completed in the fall of 1896, and Mr. Bailey returned to Elmira, where, for nearly two years, he was in the employ of the American Bridge Company's Engineering Department at its Elmira Plant. This engineering experience was invaluable to him, as it gave him a direct knowledge of design, layout, and construction of the various types of bridges, which was to serve him throughout the remainder of his engineering career.

In 1898, Mr. Bailey took the position of Resident Engineer at Caledonia, N. Y., with the Lehigh Valley Railroad Company, but only remained a short time, as in the early part of 1899, he accepted the position of Assistant Engineer, in the Construction Department, with the New York Central and Hudson River Railroad Company, with offices in Albany, N. Y. As such, he was in charge of reconstruction on the Middle Division, which included the elimination of grade crossings, track elevations, a new bridge over the Hudson River, at Albany, as well as a new passenger station, with subways to the various tracks. This work, including the new bridge over the Hudson River, on the site of the old bridge, was accomplished without the delay of a single train.

Completing this construction work in the summer of 1901, Mr. Bailey accepted a position as Construction Engineer with the Sonora Railroad of Mexico (Southern Pacific of Mexico), with headquarters at Guaymas, Sonora, Mexico, but as the climatic conditions were such that he could not withstand them in his physical condition, he soon returned to the United States. After recuperating for a short time, he accepted the position of Assistant Engineer in charge of construction with the St. Clair Bridge and Terminal Railroad Company (subsidiary of the Crucible Steel Company), at Pittsburgh, Pa. This work included the terminal facilities of the Clairton Steel Plant, at Clairton, Pa., as well as connections with the Pittsburgh, Virginia and Charleston Division of the Pennsylvania Railroad on the west side of the Monongahela River, and the Pittsburgh and Lake Erie Railroad on the east side of the same river. The bridge over the Monongahela River, with its approaches, was the principal engineering feature of this work. The structure has a clearance of 80 ft., with a main channel span of 500 ft., which is of steel arch design; it is also a combination railroad and highway bridge with upper and lower decks.

In January, 1902, after the completion of the Monongahela River Bridge, Mr. Bailey accepted a position with the Little Kanawha and the Buckhannon and Northern Railroad Companies, extensions of the Wabash Railroad in West Virginia, as Locating Engineer and, later, as Division Engineer, with headquarters first at Parkersburg and subsequently at Fairmont, W. Va. The construction of these railroads was abandoned in January, 1904, after all grading and culvert work was practically completed, which, again, made a change of position necessary.

Remaining in Fairmont, Mr. Bailey was soon employed on the location of the Fairmont and Mannington Railroad, a distance of 18 miles. After the completion of the survey, he accepted the position as Manager, and construction was immediately started, but because of the depression current at that time, the Company was unable to finance the completion of the work.

The Fairmont and Clarksburg Traction Company was contemplating the building of a connecting line between these two cities and early in 1905 Mr. Bailey was made Chief Engineer of this Company. Surveys were immediately started on this work, and by the end of 1906, the construction of a rapid transit line, 33 miles long, was completed between Fairmont and Clarksburg; this line passed through many mining towns and was a model of interurban construction.

In 1907, Mr. Bailey moved to Buffalo, N. Y., where he was made Assistant Chief Engineer of the Buffalo and Lake Erie Traction Company, in charge of all structural design; as this construction work closed down in the winter of 1907–1908, Mr. Bailey was sent by the holding syndicate of the Traction Company to report on an irrigation project in the Bitter Root Valley of Montana. His report was accepted, and he was made Chief Engineer of the Bitter Root Valley Irrigation Company. He returned to Hamilton, Mont., at once assuming active charge of the work, which included the construction of an immense earth dam at the head of the canal that impounded the waters for irrigation (now known as Lake Como); a main canal of 80 miles, with a cross-section of 18 ft. on the bottom, with $1:1\frac{1}{2}$ slopes, and capable of carrying from 6 to 7-ft. depth of water. This necessitated the construction of thousands of feet of wood flume, two major inverted siphons—one crossing the Bitter Root River and the other the Sleeping Child Creek Canyon; also miles of lateral ditches for the distribution of the water. Mr. Bailey was Manager as well as Chief Engineer in 1910 and until the completion of the work in 1911.

From 1911 to 1914, he carried on a general engineering and contracting business in Hamilton, Mont. In 1914, he went to Alaska as Locating Engineer for the Alaska Engineering Commission, with headquarters at Fairbanks. While here Mr. Bailey located the Alaskan Railroad, from Seward to Fairbanks, a distance of 471 miles, and was Division Engineer in charge of construction until his return to his now favorite State—Montana—in 1920, where he remained until his death.

In 1921, he accepted the position of Bridge Engineer with the Montana Highway Commission. In this capacity, he designed and constructed numerous bridges throughout the entire State of Montana, the most important of which was one over the Missouri River in Eastern Montana. He remained with the Montana Highway Commission until his death which occurred on April 29, 1931, in Helena.

It was Mr. Bailey's interest in his work that brought on the sickness that caused his death; a few days before, he had gone from Helena to Cascade where some bridge work was in progress; while looking after this work, a sudden and extreme change in weather conditions (from mild spring weather to a blizzard) occurred; as accommodations were poor, the exposure was more than his constitution could withstand; returning to Helena on Saturday, he died the following Wednesday.

He was borne to his last resting place in Forestvale Cemetery, Helena, on Saturday, May 2, 1931, by members of the Engineering Staff of the State Highway Commission, with whom he had worked for years.

Although Frank Harrison Bailey was well and favorably known as an Engineer in a large part of the United States, it was in his adopted State of Montana that he was most intimately acquainted, not only with those of his profession, but with the people in general. He was loved by all who knew him for his pleasing disposition and his willingness to assist others in their work or in their daily life. He was greeted in all sections of the State with a glad hand and cheery "Hello Dad."

Shortly after Mr. Bailey was established in the engineering and contracting business in 1890, he entered into life partnership with Myrtle L. Welliver, then a school teacher and also a graduate of the Mansfield State Normal School, where they first met. Mrs. Bailey was his constant companion from this time on and was not only a faithful wife but a good adviser.

He is survived by his widow, Myrtle L. Bailey, of Helena; two sisters, Mrs. Eula I. Beach and Mrs. May H. Trowbridge, of Elmira, N. Y., and three brothers, Earle C. Bailey and J. O. Wright Bailey, of Fort Lauderdale, Fla., and Ralph J. Bailey, of Portland, Ore.

Mr. Bailey was elected a Member of the American Society of Civil Engineers on January 14, 1918.

SAMUEL POND BAIRD, M. Am. Soc. C. E.[1]

DIED NOVEMBER 6, 1931

Samuel Pond Baird, the son of Samuel W. and Sarah (Pond) Baird, was born in Portsmouth, Ohio, on September 19, 1865.

Mr. Baird was always interested in things experimental and was a pioneer in the electrical field, being associated with the construction and operation of the first electric light and power plants in Portsmouth, Ohio, St. Louis, Mo., Sedalia, Mo., and Belleville, Ill. With the problems of power plant building, construction of track, etc., his interests gradually turned from the purely electrical to construction problems in general, and he built railroads, steel plants, brick plants, highways, sewerage systems, water-works, and laid out real estate developments. This work took him to many places where he always made many warm friends. In 1893, Mr. Baird built the first electric railway in Portsmouth, Ohio, and operated the System which is still running, as Superintendent and General Manager for twelve years.

After 1910, Mr. Baird maintained his home at Columbus, Ohio. He spent a number of years in Charleston, W. Va., where he rebuilt the plant of The Standard Brick Company and remained for a time as its Superintendent and General Manager. In Clearwater, Fla., and in Shelby, N. C., he was Resident Engineer in charge of the construction of large real estate developments.

---

[1] Memoir prepared from information on file at the Headquarters of the Society.

At the latter place, at Cleveland Springs Estates, the work included ing of a golf course, swimming pool, and Club House, as well as th roads, sewers and sewage disposal plant, water-works system, and electr needed to make a perfect residence community. His work in converti hilltop section of his native town of Portsmouth into a residental secti beautiful homes, was also always a great satisfaction to him.

It had been his plan to retire at some future time to spend his last ye in the congenial climate of Western North Carolina at a delightful sp near Shelby. Little did he, or those nearest to him, dream that he would b cut off so suddenly from the work that he loved. Mr. Baird had always been a man of rugged health and great energy. When it was found that an operation was imperative, every one counted on his robust health to carry him through. He rallied splendidly until the fourth day when his heart suddenly failed and he passed away on November 6, 1931, in Grant Hospital, Columbus, Ohio.

Mr. Baird was married in Portsmouth, Ohio, on April 4, 1888, to May Johnson who survives him, with two children, Samuel P. Baird, Jr., of Akron, Ohio, and Madeline Baird Porter, of Youngstown, Ohio.

He was an active and interested member of the Protestant Episcopal Church, and wherever his work took him, he always made a church connection and became a valued member of a number of different parishes, serving on the vestries on several occasions.

In addition to his varied experience as an Engineer it is fitting that tribute be paid him as a man. Many a young engineer owes his success in no small way to Mr. Baird's kindly encouragement and timely advice. He was never too busy with personal affairs to lend a listening ear to another's need. A charming loyal friend, genial, even tempered, strong, capable, and willing, a lovable personality—his memory will be valued by many warm friends.

He had been a frequent contributor to such engineering magazines as *Engineering News-Record, Concrete,* and *Roads and Streets.* His ideas were always practical, and have been followed with profit by many.

Mr. Baird was elected an Associate Member of the American Society of Civil Engineers on March 1, 1899, and a Member, on September 4, 1906.

BERNARD ARTHUR BEHREND, M. Am. Soc. C. E.[1]

Died March 25, 1932

Bernard Arthur Behrend was born on May 9, 1875, at Villeneuve, Switzerland, the son of Moritz and Rebecca (Wolf) Behrend. His early education was by private tutor, and in England, followed by studies for the degrees of Civil Engineer and Mechanical Engineer at the Polytechnic Institute, at Charlottenburg, Germany. From 1890 to 1894, he continued his studies at the

---

[1] Memoir prepared by Carl J. Fechheimer, Cons. Engr., Milwaukee, Wis.

University of Berlin, and at Paris, France, and London, England. Subsequently, for about a year, he was Assistant to Gisbert Kapp, as a Designer of power plants.

From 1895 to 1898, Mr. Behrend was Assistant to the Chief Engineer of the Oerlikon Company, in Switzerland, in charge of the Experimental and Testing Departments, on the development and design of electrical machinery and the design of the Jungfrau Railway. It was during the early part of this period that he originated and developed the circle diagram for calculating the performance of induction motors in a simple and direct manner; this was an unusual accomplishment, particularly for one so young.

In 1899, Mr. Behrend came to the United States, and early in 1900 gave a course of lectures at the University of Wisconsin, Madison, Wis., on what was then a most obscure subject, "The Theory and Design of Induction Motors." The substance of those lectures he included in a book, "The Induction Motor, Its Theory and Design," which appeared in 1901. This book was also published in French in 1902 and in German in 1903. In that work the then little understood single-phase, as well as the polyphase, motor was treated.

Mr. Behrend became associated with the Bullock Electric Manufacturing Company, in Cincinnati, Ohio, in 1900, and was soon elevated to the position of Chief Engineer. Until the time of his connection with that Company, only direct-current machinery had been built there, and it was he who successfully designed alternating-current machinery, including alternating-current generators and induction motors, many of them of difficult ratings for the time at which they were built. His earliest salient pole alternators were of the revolving field type with the poles dovetailed to the spider, and the field windings were constructed of copper bent on edge, constructions which have been standard in most machines for many years. In 1903, he presented a paper entitled "The Experimental Basis for the Theory of the Regulation of Alternators,"[2] in which he clearly called attention to the errors of methods then in use for determining regulation, and suggested improved methods of computation, thereby paving the way to methods since adopted by the Standards Committee of the American Institute of Electrical Engineers.

Mr. Behrend recognized at an early date that it was more important that alternators be proportioned so that they maintain their voltages with loads at low lagging power factors than to possess close inherent voltage regulation, a practice that has since become universal with all builders. Whenever possible, his alternators were tested at nearly zero power factor, this being obtained by operating as load other synchronous machines under-excited and the machine in test over-excited. It was often difficult or impossible to secure an adequate load in that manner, so he devised the "split-field method," in which one part of the machine had lagging, and the other leading, current. He presented a paper[3] on that subject at the Electrical Congress at St. Louis, Mo., in 1904.

---

[2] *Transactions,* A. I. E. E., Vol. XXI (1903), pp. 497–517.

[3] The Testing of Alternating-Current Generators", *Transactions,* International Electrical Cong., St. Louis, 1904, Vol. I, pp. 528–541.

An interesting early achievement was the linkage, at Montreal, Que., Canada, in 1901, of the power from the Lachine Rapids, the Montreal Light, Heat, and Power Company, and Shawinigan Falls, eighty miles distant. It was the first successful paralleling of several large power stations connected through transmission systems and synchronous frequency changers, undertaken at a time when parallel operation of synchronous machinery was imperfectly understood. That work was done by Mr. Behrend in collaboration with Ralph D. Mershon, M. Am. Soc. C. E.

In 1903, the Bullock Company built its first turbo-alternator, which was exhibited at the Louisiana Purchase Exposition in 1904; it was driven by a Hamilton steam turbine. Mr. Behrend pointed the way in the mechanical construction of steam turbine-driven alternators at a time when salient poles and parallel slots were used. From the start he used radial slots, the coils were retained in position against centrifugal forces by non-magnetic wedges in the rotor body, and the coil ends were supported by steel rings placed over their outer periphery. That construction has since become standard with all manufacturers of turbine generators.

About 1904, the Bullock Company was taken over by the Allis-Chalmers Company, and a few years later Mr. Behrend and his staff were transferred to the main plant at West Allis, near Milwaukee, Wis., he retaining the position of Chief Electrical Engineer. He was also made Consulting Engineer of the Allis-Chalmers Bullock, Limited, at Montreal.

The Allis-Chalmers Company started to build steam turbines about the time it absorbed the Bullock Company, and Mr. Behrend designed and developed the generators which were driven by the turbines. For the time at which they were built, they were of difficult ratings, and many mechanical and electrical problems required his solution.

One of the problems that Mr. Behrend was called upon to solve was the successful parallel operation of gas-engine-driven alternators, about which little was known. Adequate damping to minimize the effects of fluctuation in applied torque was provided by means of solid steel poles and a low-resistance short-circuited winding. There was danger of having the natural and forced frequencies too near each other, with the possibilities of resonance. To avoid this, it was necessary to calculate the natural frequency from the torque in the generator per degree of displacement and the moment of inertia of the rotating parts. Mr. Behrend claimed that superior operation would be obtained by so choosing the fly-wheel that the natural frequency would be between two forced frequencies, rather than lower than the lowest frequency. The fly-wheels thus chosen were lightened, and the parallel operation was improved. Most of those large machines were built for the United States Steel Corporation, for use in its reconstructed power-houses at Rankin, Pa.; the Illinois Steel and the Indiana Steel Companies, at South Chicago, Ill., and Gary, Ind., respectively; and the American Steel and Wire Company, at Cleveland, Ohio. In all, the gas from the blast furnaces, which hitherto had been wasted, was used directly in the prime mover. In this work, his assistant, Mr. A. B. Field, collaborated.

Mr. Behrend early recognized that the distribution of stresses in rotating disks is a complicated phenomenon, and while with the Bullock Company he made tests on lead disks to study their permanent deformation when driven at high speed, thereby checking the theory on which he had also done considerable work. In his paper,[4] "A New Large Generator for Niagara Falls," presented to the American Institute of Electrical Engineers in 1908, he shows how the stresses are distributed, both radially and tangentially, in a high-speed disk. These were perhaps the earliest published curves of that character.

Mr. Behrend left the Allis-Chalmers Company in 1908, and assumed charge of the Power Division of the Engineering Department of the Westinghouse Electric and Manufacturing Company, at East Pittsburgh, Pa. He had realized the danger of failure occurring in high-speed turbine generator rotors from lack of homogeneity, from internal shrinkage stresses, or from pipes, cracks, etc., which are likely to appear in large steel castings or forgings. Recognizing that steel plates, when suitably forged or rolled, are practically homogeneous, he invented and developed the plate-rotor construction which the Westinghouse Company has used ever since in its large turbine generators of more than two poles. The construction is one that showed great ingenuity on the part of the inventor.

In 1911, Mr. Behrend opened an office as Consulting Engineer in Boston, Mass., and was retained by the Westinghouse Company as a Consultant, in which capacity he advised on many difficult engineering problems. In 1921, the second edition of his book, under the title of "The Induction Motor and Other Alternating Current Motors," appeared, much enlarged and revised, with treatments of certain types of motors omitted in the first edition. In 1926, he gave up the Boston Office, and continued his consulting practice at Wellesley Hills, Mass. He made an extensive study of machine tools and secured various patents on signal improvements that he affected.

Mr. Behrend was awarded a Gold Medal at the St. Louis Expostion in 1904, and the John Scott Medal by the City of Philadelphia, Pa., with the recommendation of the Franklin Institute, in 1912, for meritorious achievements in high-speed machinery. In 1931, the honorary degree of Doctor of Engineering was conferred upon him by the University of Darmstadt, Germany, "in appreciation of his meritorious development of electrical machinery, particularly of polyphase and single-phase induction motors."

Dr. Behrend, as a leader, inspired his associates and assistants and always offered words of encouragement. He was a man of vision, and one who knew well how to select men for his Engineering Staff. He was an able pioneer, who recognized while still very young, how machines should be designed, and always showed sound judgment. He was a great reader and student of the classics, in engineering and literature in general. He had a magnetic personality and a brilliant mind, but was of an exceedingly modest and retiring nature. Distinguished equally for scientific knowledge and constructive achievement, Dr. Behrend was an Electrical and Mechanical Engineer of more than National prominence. He had about seventy patents assigned to him, and was the author of numerous monographs and articles, among which may be mentioned: "The Debt of Electrical Engineering to C. E. L. Brown" (1901); "Engineering Education" (1907); "The Career of Oliver Heaviside" (1925); "The Work of Oliver Heaviside" (1928); and "Recent Developments in Precision Bench Tools" (1923). He was Non-Resident Lecturer at McGill University, the University of Wisconsin, and Leland Stanford, Jr., University.

---

[4] *Transactions*, A. I. E. E., Vol. XXVII (1908), pp. 1057–1068.

In 1926, he was married to Margaret P. Chase, of Boston, Mass., who survives him.

Dr. Behrend served on various committees of the American Institute of Electrical Engineers, such as the Edison Medal Committee, and was a Past-Chairman of the Electrical Machinery Committee. He was a Senior Vice-President of the Institute and was active on the Board of Directors.

He was a Fellow of the American Academy of Arts and Sciences, American Institute of Electrical Engineers, American Association for the Advancement of Science, and American Physical Society. He was a member of the British Institution of Electrical Engineers, American Society of Mechanical Engineers, Franklin Institute, and Society for the Preservation of New England Antiquities. He was also a member of the Engineers Clubs in New York, N. Y., and Boston, and the Athletic Club, in Pittsburgh, Pa.

Dr. Behrend was elected a Member of the American Society of Civil Engineers on October 5, 1909.

JAMES WARTELLE BILLINGSLEY, M. Am. Soc. C. E.[1]

DIED AUGUST 17, 1931

James Wartelle Billingsley, the son of James J. and Georgine (Wartelle) Billingsley, was born at Arcadia, La., on January 29, 1880. He received his engineering education and training at Rensselaer Polytechnic Institute, Troy, N. Y., where as an outstanding student he was elected to Sigma Xi, an honorary fraternity for scientific research. He was graduated in 1902 with the degree of Civil Engineer.

Mr. Billingsley immediately began moulding an engineering experience which was to serve him well in his future work as a Consulting Engineer in extensive industrial and economic developments. His first position, in 1903, was with Sanderson and Porter, Engineers and Contractors, New York, N. Y., principally on electric interurban railway construction in Connecticut. In 1904 he was employed by the Westinghouse Electric Company at East Pittsburgh, Pa., in the Testing and Fabricating Departments. This engagement was in the nature of post-graduate work.

From 1905 to 1907, Mr. Billingsley was with Sanderson and Porter as Principal Assistant Engineer for the Local Manager in New Orleans, La., and was engaged in executing the work of reconstruction of the public utilities of New Orleans, including the installation of a new power plant for the New Orleans Railways and Light Company, with new electric and arc light system, the underground conduit system, and the laying of a submarine cable across the Mississippi River to furnish light and power to Algiers, New Orleans, La.

---

[1] Memoir prepared by a Committee of the Louisiana Section consisting of E. S. Lanphier, John T. Eastwood, and A. T. Dusenbury, Members, Am. Soc. C. E.

From 1908 to 1914, he was associated with Fred A. Jones, Consulting Engineers, of Houston and Dallas, Tex., first as Manager of the New Orleans Office and then as Assistant to the President. During this period Mr. Billingsley was in direct charge of all engineering work included in the construction of steam railways, power plants, water-works, hotels, and office buildings, and other types of construction.

In 1912, he was engaged with John W. Alvord, M. Am. Soc. C. E., Consulting Engineer, of Chicago, Ill., and the late Hiram Phillips, M. Am. Soc. C. E., to investigate and report upon a new water supply system for Oklahoma City, Okla. An exhaustive and complete report was made which was a most valuable contribution to the water-works art.

From 1914 to 1931, he was located in New Orleans, engaged in private practice as Consulting Engineer. Associated with him was his brother, Mr. Fred N. Billingsley, who, later, became his trusted and valued partner. It would be difficult, indeed, to cover in detail the many and varied extensive works of public and private character carried on by Mr. Billingsley during these seventeen years. Mention of the more important undertakings will suffice to convey the wide scope of his operations—water-works, sewerage and drainage, paving work, irrigation and reclamation, sea walls, highways, bridges, wharves and port development, electric and steam power plants, appraisals and reports on construction, and the supervision for bond and investment houses in connection with the financing of industrial plants and other construction work. He was engaged by public utility companies and cities, particularly upon matters pertaining to adjustment and arbitration, as an expert where conflict between the city authorities and the utility companies occurred in fixing rates for service. Notable among these cities are New Orleans, and Memphis, Tenn. For the last few years, he was retained by the City of New Orleans as Consultant in connection with regulating jurisdiction over the public utilities supplying electric, gas, and street railway service to the city.

Mr. Billingsley was also a pioneer in good roads in Louisiana, contributing valuable data and articles in his characteristic and sincere manner. He acted as Engineer for a number of Parishes in the State, namely, Richland, Claiborne, Catahoula, and Ouachita. His work involved many millions of dollars.

During the World War he served under the Chief of the Engineering Division of the United States Housing Corporation, in charge of all engineering work for housing development at New Orleans.

He was well known for his works of charity, both public and private, and gave generously to local charities.

Mr. Billingsley was a striking example of the economics engineer of to-day, with the ability to visualize in such manner as to prove practicable of execution. His judgment was sound and his wide knowledge of business methods, together with his insight of the financial operation of industrial, economic, and engineering problems, made him a most valuable asset to the community. To his social and personal charm he added the personality of his blithe and optimistic spirit, and, in his passing, the Engineering Profession and the City of New Orleans loses one of its ablest leaders and a genuinely constructive force for sound community upbuilding.

He is survived by his widow, the former Irene Rice, of New Orleans, whom he married in 1919.

Always closely in touch with technical activities and advancements, Mr. Billingsley was a member of the American Society of Municipal Engineers and the Louisiana Engineering Society. Prominent in the civic and social life of New Orleans, he was a member of the Boston, Pickwick, Louisiana, New Orleans Country, Metairie Golf, and Delta Duck Clubs.

Mr. Billingsley was elected an Associate Member of the American Society of Civil Engineers on May 6, 1908, and a Member on June 24, 1916.

FRED MILTON BISBEE, M. Am. Soc. C. E.[1]

Died May 4, 1931

Fred Milton Bisbee was born on September 27, 1853, in Brunswick, Me., the son of John S. Bisbee and Eliza (Dustin) Bisbee. His mother was a descendant of Hannah Dustin of Colonial fame.

The early years of Mr. Bisbee's life were spent in Maine, and there he completed his education. He was graduated from Westbrook Seminary and the University of Maine, receiving the degree of Civil Engineer from the latter institution in 1876.

In 1878, Mr. Bisbee went West and for a few weeks was employed by the Kansas City Water-Works Company as Clerk. On May 1, 1878, he obtained employment in the Engineering Department of The Atchison, Topeka and Santa Fé Railway Company and was sent to "the front" of the main line then being built in New Mexico. When, in June, 1881, the line was completed into El Paso, Tex., he continued this pioneer railroad construction with the Mexican Central Railway Company, being placed in charge of rail-laying south of El Paso. There he constructed the first track connecting the United States with the Republic of Mexico. This event, attended with considerable ceremony, took place August 2, 1881, at El Paso. Governor Terrazas, of Chihuahua, Mexico, drove the golden spike.

Upon the completion of this work, Mr. Bisbee constructed another important stretch of track on the Mexican Central Railway at Chihuahua. This was a test of his untiring energy as it was necessary to expedite the work with all possible haste in order to obtain a Government bonus that was to be granted if Chihuahua was reached upon a stipulated date. This extension of the Mexican Central Railway was completed on September 15, 1882, and in celebrating the event, Governor Terrazas drove the same spike that was used at El Paso the previous year. Later, this spike was presented to Mr. Bisbee and was in his possession during his life time. It recently was added to the collection of the Texas State Historical Association, at Austin.

---

[1] Memoir prepared by William Pirschell, Office Engr., A. T. & S. F. Ry., Amarillo, Tex.

During 1883, Mr. Bisbee was Engineer in the Maintenance-of-Way Department of the National Railways of Mexico, which position he held until the latter part of 1884, when he returned to The Atchison, Topeka and Santa Fé Railway Company. During the remainder of that year and during 1885, he was in charge of construction of branch lines in Kansas, and, in 1886, was employed as Levelman on surveys. With the exception of a few months on the construction of the Colorado Midland Railroad, he continued with the Santa Fé, for the most part on construction work on the line between Kansas City, Mo., and Chicago, Ill., until February, 1888, when, for a time, he was employed as Superintendent of Construction for Lantry and Sons, Railroad Contractors. In December, 1890, Mr. Bisbee returned to the Santa Fé, and during 1891 and 1892 was General Roadmaster on the Gulf, Colorado, and Santa Fé Railroad. From 1893 to 1896 he was Superintendent of Bridges and Buildings for that Company, and then, for three succeeding years, he was with the St. Louis-San Francisco Railroad Company in a similar capacity. In 1899, he was employed by the Tennessee Central Railroad Company, as Chief Engineer, but again returned to the Santa Fé on July 1, 1904, as District Engineer of the Western Lines with headquarters at La Junta, Colo. On April 2, 1913, he was appointed Chief Engineer of the Western Lines with office at Amarillo, Tex., and continued in this position until his retirement on November 1, 1922. Since that time he had been living in Hollywood, Calif., where he passed away suddenly on May 4, 1931.

Mr. Bisbee's service with The Atchison, Topeka and Santa Fé Railway Company totaled thirty-three years of varied experience, such as Engineer of Track Construction on the pioneer extensions of the lines, General Superintendent of Bridges and Buildings, General Roadmaster on Maintenance of Way, and as District Engineer, and, during the closing years of this service, as Chief Engineer. In the latter capacities he had charge of many permanent improvements, such as construction of second track, new bridges, heavier rail laying, ballasting, changes of line, and reduction of grades; the westbound tunnel at Raton, N. Mex.; many station buildings and Harvey Houses, fuel and water stations, and mechanical facilities. A noteworthy example of the last mentioned class of work is the locomotive repair facilities and shops at Albuquerque, N. Mex.

He was a man of marked personality and untiring energy; essentially a man of action he vigorously prosecuted whatever work he had in hand. He was a loyal friend, constant and sympathetic. He was generous in giving advice and a helping hand to the unfortunate. His interest in civic matters in all communities in which he lived was very keen, and he had a wide acquaintance in all walks of life. He was approachable at all times, possessed sound judgment in making decisions, and was always fair in his business transactions.

Mr. Bisbee was a devoted husband. He took great interest in his home and those who knew him there, admired and loved him for the more sacred things of life for which he so firmly stood. Parity of age was not required by Mr. Bisbee in order to be listed among his friends, for he was particularly attracted to young people even as they were attracted to him.

He was a member of the Massachusetts Chapter of Sons of the American Revolution, and a Thirty-second Degree Mason.

He was married on November 4, 1884, to Addie Hamilton, who passed away June 11, 1911. On September 17, 1913, Mr. Bisbee was married to Mrs. Harriet C. Martin, who survives him.

Mr. Bisbee was elected a Member of the American Society of Civil Engineers on May 3, 1899.

HOWARD EDWARD BOARDMAN, M. Am. Soc. C. E.[1]

DIED FEBRUARY 28, 1932

Howard Edward Boardman was born in Meriden, Conn., on March 17, 1879, the son of Edward Allen and Nellie (Savage) Boardman. His ancestors had settled in Massachusetts Bay Colony in 1638. He prepared for college at the Meriden High School. In 1899, he was graduated with honors from the Sheffield Scientific School of Yale University with the degree of Bachelor of Philosophy. His engineering training as an undergraduate was in the Department of Civil Engineering and soon after graduation he served in that Department as an Instructor in a summer course in surveying. In 1931, the honorary degree of Master of Arts was conferred on him by Yale University.

Mr. Boardman began his professional career in the fall of 1899 as Draftsman in a consulting office in Philadelphia, Pa., but in the spring of 1900 he became Instrumentman on location with the Pennsylvania Railroad Company. During the next two years he was Assistant on the Engineering Corps and Acting Supervisor on the Pennsylvania Lines West, engaged in general maintenance on the Main Line Division and in charge of the construction of a large interchange yard.

For seven years, from 1902 to 1909, he was, successively, Instrumentman, Chief of Party, and Assistant Engineer on work pertaining to the construction of the North River Tunnels under the Hudson River to the Pennsylvania Station in New York, N. Y. His work involved the preliminary and final triangulation surveys, contract drawings, and estimates, and the construction of the cast-iron subaqueous and concrete-lined tunnels. He was in charge of all estimates, final detailed cost records, and reports, and of the alignment, until the junction of the tunnels from the opposite shores.

---

[1] Memoir prepared by J. C. Tracy, M. Am. Soc. C. E.

From 1909 to 1912, Mr. Boardman was Senior Assistant Engineer, and then Division Engineer, on the Missouri Pacific Railroad. He was in charge of the maintenance of a division 525 miles long and, later, of all construction work planned in the office of the Chief Engineer of Maintenance of Way.

From 1912 to 1916, he was Chief Assistant Engineer of the Underground Lines of the Buenos Aires Western Railway in South America. He was in direct charge of the construction of 3½ miles of single-track freight tunnel, ½ mile of double-track passenger tunnel, and the joint underground transfer station under the City of Buenos Aires.

Beginning in 1916, Mr. Boardman served for seven years as Engineering Assistant to the General Valuation Counsel of the New York Central Lines. As such, he was engaged in organizing the valuation work at the various headquarters of the System, and in making investigations, special reports, and cost analyses.

For a period of six years, beginning in 1923, he was not, strictly speaking, engaged in engineering. During this period he held three positions. As President and Treasurer of Foster Merriam and Company, of Meriden, hardware manufacturers and light gray iron and brass founders, he entirely and successfully re-organized the Company. Later, he became Manager of Engineering and Sales of the Divine Brothers Company, of Utica, N. Y.; and, still later, Manager of Research and Assistant to the President, National Industrial Conference Board, New York City.

In 1929 Mr. Boardman returned to engineering, as Construction Engineer for the Boston and Maine Railroad Company, in charge of important betterments, including nine miles of heavy, new-line construction in the Connecticut Valley.

In July, 1931, he began his work at Yale University as the first Dudley Professor of Railroad Engineering, a professorship established under the wills of the late Plimmon H. Dudley, Consulting Engineer of the New York Central Lines, and his wife, Lucy Bronson Dudley. This position offered an exceptional opportunity for research in the field of railroad engineering, and Professor Boardman entered upon the work with enthusiasm and energy. He began at once to make a thorough and comprehensive study to determine in what type of research he could render the greatest service. He sought and obtained the advice of many leading railroad officials and engineers and, at the time of his death, he was planning conferences with many others. It was his desire to secure the co-operation of the railroad companies in any research that he might undertake, and he had already received encouraging assurance of such co-operation. As a result of this preliminary study, he had begun to outline a program of investigations that gave promise of important results.

On September 24, 1903, Professor Boardman was married to Enna M. Jenkins, of Allegheny, Pa., who, with their two sons, Edward T. and Howard F. Boardman, survives him.

He was a member of a number of scientific and technical societies, including the American Society of Mechanical Engineers; the American Railway

Engineering Association; the Connecticut Society of Civil Engineers; and the Yale Engineering Association.

A hard and tireless worker, unusually efficient in everything he did, Professor Boardman, nevertheless, had broad interests outside his profession. He was active in promoting civic welfare, and was particularly interested in work for boys and young men. Beneath a quiet, modest demeanor and a winning personality, there were the qualities of a man of power and of high ideals. A forceful, successful engineer, he was also a thorough student, interested in research.

Professor Boardman was elected a Junior of the American Society of Civil Engineers on October 7, 1902; an Associate Member on January 4, 1905; and a Member on October 1, 1912.

WILLIAM JAMES BOUCHER, M. Am. Soc. C. E.[1]

DIED SEPTEMBER 14, 1929

William James Boucher was born in Jersey City, N. J., on January 19, 1875, the son of John and Lydia (Anderson) Boucher. He was of French-German and English descent; his ancestors on his father's side came from Holland in 1645, settled in Bowling Green, New York City, and, later, moved to Castleton, near Albany, N. Y., where Mr. Boucher's father was born. As a young man Mr. Boucher's father went to New York City, to enter business. He died when his son was twenty-two years of age and, after his death, his widow and son came from Albany to live in New York.

In his early years Mr. Boucher evidently had a strong liking for mechanical appliances, perhaps inspired by his occasional visits to the roundhouses and shops of the railroads terminating on the west side of the Hudson River. A little later, electric apparatus, such as electric bells, induction coils, and frictional electric machines appeared to have engaged his attention. It was quite natural, therefore, that he should take up the study of Mechanical Engineering at the Stevens Institute of Technology in Hoboken, N. J., from which he was graduated as a Mechanical Engineer in 1896.

From 1896, following his graduation, to the time of his death in 1929, Mr. Boucher was professionally engaged in a considerable number of varied occupations which gave him a broad background of engineering knowledge. While his first engagements covered the field of mechanical engineering, his early association with contractors and contact with construction work, coupled with his adaptability to new problems, eventually led him to devote himself principally to civil engineering construction work. In this field he became connected, partly in responsible positions, with some of the most important projects.

Mr. Boucher's successive engagements and positions were, briefly, as follows: From 1896 to 1900, various positions which involved drafting, designing, shop work, inspection and installation of gasoline and oil engines, electric motors, elevators, controllers, steam engines, boilers, blowers, mechanical draft and heating apparatus, street cars, steam railroad cars, locomotives, and shop layouts; from 1900 to 1901, Chief Draftsman in the Mechanical Department of the Central Railroad Company of New Jersey; from 1901 to 1909, Draftsman and, later, Office Engineer with the Rapid Transit Subway Construction Company, Contractors for the first rapid transit subway in New York City; from 1909 to 1910, Office Engineer and Purchasing Agent for the Gore-Meenan Company, Contractors, in charge of purchase of equipment and supplies for the construction of 4 miles of the Catskill Aqueduct and a 1-mile rock tunnel in Connecticut; from 1910 to 1911, Engineer for the Chicago Subway Commission, specializing in designing and estimating of river tunnels, stations, drainage, and ventilation; from 1911 to 1912, Engineer for the Mineral Point Zinc Company and the New Jersey Zinc Company, Depue, Ill., and New York City, in charge of cost estimates for a $1 700 000 addition to the Company's zinc smelting and sulfur acid plants in Illinois and Pennsylvania; and from 1912 to 1919, Assistant Engineer with the Degnon Contracting Company, Contractors, in New York City, engaged in estimating costs, planning and supervising heavy construction work, comprising subways, tunnels, steel viaducts, foundations, sewers, water pipes, and electric-conduit lines.

---

[1] Memoir prepared by O. H. Ammann, M. Am. Soc. C. E.

During the World War (1918) Mr. Boucher was engaged as Engineer in the construction of the Port Terminal at Charleston, S. C., a $17 000 000 rail-and-water proposition, with buildings for the storage of explosives, barrack and camp buildings, roads, and dock.

From 1919 to 1920, he served as Engineer for the Philadelphia Subway Construction Company, Philadelphia, Pa., Contractors for $1 200 000 sewage treatment plant and for nine miles of State highway; and from 1920 to 1923, he was Assistant Supervisor, Department of Way and Structures, Eighth Avenue Railroad Company and Ninth Avenue Railroad Company, New York City, in charge of construction, maintenance, and repair of street railroad tracks, underground conduit systems, storage yard, and shop buildings.

From 1923 until the time of his death, Mr. Boucher was connected with the Port of New York Authority. In the capacities of Designing Engineer and Assistant Chief Engineer, he made investigations for additional tunnels under the Hudson River and for a belt-line railroad in New Jersey and in connection with inland freight stations. From 1926, he acted in the capacity of Engineer of Construction and, as such, had charge of the field operations in connection with the construction of the two bridges across the Arthur Kill, at Perth Amboy, N. J. (Outerbridge Crossing), and at Elizabeth, N. J. (Goethals Bridge), the bridge across the Kill van Kull, at Bayonne, N. J., and the preliminary field surveys for the bridge across the Hudson River, at Fort Lee, N. J. (George Washington Bridge).

Mr. Boucher manifested unusual loyalty to his employers and devotion to his work. Untiring in his efforts to accomplish results, he did not shrink from devoting long hours to his duties. Somewhat critical of those whom he did not know, he became their ardent collaborator when convinced of their sincerity and good will. Thus reserved in the selection of his friends, he was most devoted and loyal to those few with whom he was on intimate terms. All those with whom he came in daily contact benefited by his gentlemanly courtesy and cheerful, unassuming disposition.

Besides the heavy occupational duties of his last few years, Mr. Boucher found time and energy to devote himself wholeheartedly to various social and professional interests.

To his Alma Mater, the Stevens Institute, he remained a loyal friend. Its alumni, officers, and trustees find high praise for his devotion and they regret deeply his loss. Among his extra-curricular interests were the Stevens Engineering Society and the *Stevens Life,* which he edited in the last year of his college course. He was Secretary and later President of the Engineering Society. He accepted offices and responsibilities in the Alumni Association, passing through various duties to those of its Presidency in 1928, and, finally, in 1929, he was chosen a member of the Board of Trustees of the Institute.

Mr. Boucher also devoted much time and thought to the Broadway Presbyterian Church, of which he was an active Trustee.

He was not married, but his disposition reflected the happy home life which he shared with unusual filial devotion with his mother, whom he survived only a short time. He died suddenly of heart attack while bathing near Long Branch, N. J., on September 14, 1929. He lies buried at his ancestral home, Castleton, N. Y.

Mr. Boucher was elected an Associate Member of the American Society of Civil Engineers on September 6, 1905 and a Member on December 6, 1920. Throughout his membership he showed much interest in the activities of the Society and contributed to its publications and discussions. At the time of his death, he held the office of Assistant Treasurer of the Society.

WILLIAM ALGERNON BRACKENRIDGE, M. Am. Soc. C. E.[1]

Died November 29, 1929

William Algernon Brackenridge was born at Richmond Hill, N. Y., on June 15, 1858. He was the son of Gavin Brackenridge and Anne (Hurry) Brackenridge. He attended the schools of New Brighton, Staten Island, N. Y., and Toms River, N. J.

Mr. Brackenridge commenced the practice of civil engineering on surveys and construction of elevated railroads in New York, N. Y., and was engaged on this work from 1877 to 1880.

From 1880 to 1882 he was a Transitman in the Survey Corps, and Resident Engineer on surveys and construction of the Western Extension of the main line of the Delaware, Lackawanna, and Western Railroad, from Binghamton to Buffalo, N. Y.

---

[1] Memoir prepared by Harry W. Dennis, M. Am. Soc. C. E.

During 1882 and 1883 he was engaged in making preliminary surveys for the proposed Hartford and Harlem Railway, from New York City to New Britain, Conn., a project which was not built. In 1883, he became Principal Assistant Engineer of the Brooklyn (N. Y.) Elevated Railway, and was in charge of all surveys and construction.

From 1885 to 1889, Mr. Brackenridge was Principal Assistant Engineer of the Brooklyn and Long Island Cable Railway and designed and had direct charge of all surveys for underground and elevated railway structures on Atlantic Avenue, Brooklyn. He also had charge of the construction of docks, ferry slips, and general improvements for the Long Island Railroad System. In 1889, he attended the International Convention of Civil, Mechanical, and Mining Engineers held in London, England, and spent eight months in investigation and study of the principal engineering works in England, and of hydraulic works on the Continent.

Upon his return in 1890, he was associated with the late Clemens Herschel, Past-President and Hon. M. Am. Soc. C. E., in making surveys, plans, and reports to the Railroad Commissioners of the State of Connecticut on the elimination of grade crossings in the City of Waterbury.

In 1891 Mr. Brackenridge began work along the special line of engineering to which he devoted practically all his subsequent professional career, namely, the development of hydro-electric power. He accepted an appointment with the Board of Consulting Engineers then engaged in preliminary plans for the development of water power at Niagara Falls, by the Niagara Falls Power Company, which engagement resulted later in his being appointed Engineer in Charge of all the construction operations of the Niagara Falls Power Company and its allied companies, at Niagara Falls, including the main tail-race tunnel and wheel-pits, and Power Houses Nos. 1 and 2 on the American side of the river, and the development of the Canadian-Niagara Power Company in Canada. He planned and directed the execution of work in connection with the abatement of floods on the lands of the Niagara Development Company, and superintended the construction of the industrial Village of Echota, including its sewerage system, sewage disposal works, land drainage, and street paving; built the Niagara Junction Railway; and was Engineer for, and superintended the works of, the Niagara Falls Water-Works Company, including the filter plant and hydraulic pumping plant. The power stations built under his direction at Niagara Falls, N. Y., are known collectively as the Edward Dean Adams Station. His active engagement with the Niagara Falls Power Company extended from 1891 to 1904.

On March 3, 1904, Mr. Brackenridge was appointed by Benjamin B. Odell, Jr., then Governor of New York, to be one of "five expert civil engineers to act as an Advisory Board of Consulting Engineers,"[2] in connection with the expenditure of $101 000 000 authorized by the Barge Canal Law for the improvement of the New York State Canals and the construction of the Barge Canal to connect the Hudson River with the Great Lakes. Nearly every question of moment concerning the new canal was submitted to the Advisory Board of which Mr. Brackenridge continued to be a member until he resigned in the autumn of 1909, when he changed his residence from Buffalo, N. Y., to Pasadena, Calif.

---

[2] Quoted from the Barge Canal Law.

Earlier in 1909 he had been called by the Southern California Edison Company to advise in reference to repairs and reconstruction of its Kern River No. 1 Hydro-Electric Plant, the operation of which had been suspended, due to the failure of a part of its pressure main and tunnel. The work was done after his design, under his direction, and within the estimates of cost and time. In October, 1909, upon the completion of this reconstruction work, Mr. Brackenridge became Vice-President and General Manager of the Company, continuing as such until March, 1918, when he was made President. This position he held for two years, retiring to that of Senior Vice-President in March 1920, and continuing in this position until he resigned in June, 1928.

Under his direction the Company made its initial steam installation of 47 000 kw., at Long Beach, Calif., with about 90 miles of steel tower transmission line, and built its 32 000-kw. hydro-electric plant known as Kern River No. 3. Two Francis turbines to operate under a head of 800 ft. (an extreme at that time), were installed.

In 1917, a consolidation with the Pacific Light and Power Corporation was effected, whereby the Southern California Edison Company became one of the largest central station companies in the United States. Subsequent to this consolidation, Mr. Brackenridge's duties with the enlarged company were mostly executive. Following the passage of the Federal Water Power Act, he prepared and filed with the Federal Power Commission, in behalf of the Southern California Edison Company, a comprehensive plan for the power development of the Colorado River from Lees Ferry, Ariz., to Needles, Calif.

He conducted a private practice as Consulting Engineer during the period of his engagement with the Niagara Falls Power Company and the Canal Board, and from time to time throughout his nearly twenty years of association with the Southern California Edison Company, he was called upon by other companies for consultation and advice.

Mr. Brackenridge designed the initial development for the Utica Gas and Electric Company, at Trenton Falls, N. Y., for the development of 8 000 h.p., under a 266-ft. head, requiring the building of a heavy masonry dam, pipe line, storage reservoir, and power house. He was Consultant for the construction of the Thomson Plant by the Great Northern Power Company, of Duluth, Minn.; for the second development of Snoqualmie Falls, for the Seattle (Wash.), Electric Company; and for the development on the White River in Washington, by the Pacific Coast Power Company, reporting later upon the entire property of the Puget Sound Traction, Light, and Power Company, including its system of electric railways.

He was also Consultant for the financiers in connection with the Buck's Creek development of the Feather River Power Company, in California. He made reports on hydro-electric properties throughout the United States, Canada, and Mexico.

Few engineers have possessed the background of broad experience and many years of practice in their special branch of the profession that belonged to Mr. Brackenridge. During more than forty-five years he had been identified with hydro-electric power development. For several years he worked with other leaders of the electrical power industry in co-operation with legislators in undertaking to prepare Federal water power legislation which would be acceptable, not only to Congress, but to the sources of capital that would invest in hydro-electric developments on Government land. The result was the Federal Water Power Act passed by Congress in 1920.

From 1920 to 1926 Mr. Brackenridge was a member of the Water Power Committee of the National Electric Light Association. In 1923, he proposed to the Arch Dam Committee of Engineering Foundation the construction of a large arch dam for experimental purposes, and, in behalf of the Southern California Edison Company, he offered a large contribution of funds. This was the beginning of the Stevenson Creek Experimental Arch Dam Investigation carried out by Engineering Foundation.[3] Mr. Brackenridge was Trustee of the funds which were used in connection with this experiment, and he maintained a keen interest in the work and a firm belief in its value to the Engineering Profession.

He was ever a lover of animals, deeply interested in their welfare, and was President of the Pasadena Humane Society. He was also most active in humanitarian work, and was a Director of the Boys and Girls Aid Society of Pasadena.

On June 17, 1902, Mr. Brackenridge was married at Buffalo, N. Y., to Margaret Lobdell, the daughter of the Rev. Dr. and Mrs. Francis Lobdell. There are four children—Marian, Margaret (Mrs. William Ellery Hale), Anne, and William Algernon, Jr. He was the brother of Charles D. Brackenridge, and of John C. Brackenridge, M. Am. Soc. C. E.

In April, 1929, he and his family moved for a few months to Santa Barbara, Calif., where Mr. Brackenridge died on November 29, 1929.

Mr. Brackenridge was elected a Member of the American Society of Civil Engineers on June 2, 1886.

GUSTAVE MAURICE BRAUNE, M. Am. Soc. C. E.[1]

Died November 26, 1930

Gustave Maurice Braune was born at Eutaw, Ala., on March 3, 1872. His father, Gustave Braune, was a native of Freiburg, Saxony, who came to Athens, Ga., in 1850. Later, he moved to Eutaw, Ala., where he was engaged in several enterprises of a banking and financial nature. Mr. Braune's mother, Honoria Rooney, was born in Ireland. An only child, she was orphaned at an early age and came to Pensacola, Fla., with an uncle, John Gilmore, where she resided until she was married. His paternal grandfather was Charles Frederick Braune, a graduate of Heidelberg University, who later prepared students to enter that University; his grandmother was Emily Seibert.

---

[3] Report, Engineering Foundation Committee on Arch Dam Investigation, *Proceedings*, Am. Soc. C. E., May, 1928, Part III.

[1] Memoir prepared by Thorndike Saville, M. Am. Soc. C. E., and Robert Ridgway, Past-President, Am. Soc. C. E.

Gustave Maurice Braune received his preliminary education at Spring Hill College, Mobile, Ala. He then entered Washington and Lee University, Lexington, Va., from which he was graduated with honors in 1889, at the early age of seventeen.

From 1889 to 1890, he lived in Eutaw, Ala. In 1890, desiring to undertake special work in structural engineering, Mr. Braune became a student at the Royal Technical Institute at Dresden, Saxony. Here he studied under several noted German professors, and was a classmate of the late Allen Hazen, M. Am. Soc. C. E., under the famous Dr. Hubert Engels. Mr. Braune received his Diploma Ingenieure from the Dresden institution in 1895, after which he returned to Alabama. From 1896 to 1903 he was associated with the Union Bridge Company and Southern Bridge Company, first as Draftsman and, later, as Assistant Manager and Chief Bridge Designer. During this period, he designed and supervised the construction of numerous highway bridges, buildings, and bridge foundations, chiefly in Alabama and adjacent States.

From 1905 to 1907, Mr. Braune was associated with the late B. M. Hardaway, M. Am. Soc. C. E., as Chief Engineer of the B. M. Hardaway Contracting Company, in general charge of the construction of several large railway and highway bridges, as well as numerous small bridges and several concrete dams and water-power developments. Throughout his life, he was Mr. Hardaway's Principal Consultant on bridge projects, and, in his later years, developed unique methods of designing falsework and bridge erection practices which were utilized by the Hardaway Company.

From 1908 to 1911, Mr. Braune was Bridge Designer and, later, Assistant Chief Bridge Designer with the New York State Barge Canal. During this period he assisted in the design of numerous bridges and special steel structures constructed by the Barge Canal.

Late in 1911, he returned to Alabama, finding the northern winters somewhat severe for his family and himself. He was engaged for a year in Birmingham in general construction work under the name of the Braune Contracting Company, specializing in steel bridges and other structures.

Up to this time Mr. Braune had acquired a great fund of practical experience on a wide variety of problems in his special field of structural engineering. In 1912, he came into contact with Herman Schneider, Assoc. M. Am. Soc. C. E., who was just getting under way his notable development in co-operative engineering education as Dean of the Engineering School at the University of Cincinnati, at Cincinnati, Oho. Dean Schneider, with that rare vision which has been exemplified in his selection of associates, saw clearly that Mr. Braune was one of those unusual individuals who, after an extended period in the practice of engineering, are still able to adapt themselves to the rôle of engineering education.

Assistant Dean George Burns, of the University of Cincinnati Engineering School, states that Mr. Braune,

"* * * * came to this University with a wealth of practical experience, especially along the lines of bridge engineering, and this practical experience enabled him to vitalize and exemplify his instruction in Mechanics and Bridge Engineering. Shortly after coming here he was made Associate Professor, and a little later on he was given a full professorship and made Head of the Department. He was one of the outstanding men of the Engineering Faculty of the University of Cincinnati during the years he was associated here. He probably held as high a place in the affection of his students as any man who has ever been a member of this Faculty.

"Professor Braune took a very prominent part in the Engineers Club of Cincinnati and, at one time, he served as a Director of this organization. He was also very active in the Cincinnati Section of the American Society of Civil Engineers. At the University he organized the Student Chapter of the American Society of Civil Engineers, and the students, in return, as a mark of the high esteem in which they held him, called the organization the Braune Society of Civil Engineers, which still continues under that name.

"Professor Braune was one of Dean Schneider's ablest lieutenants in promoting the co-operative scheme of education. He had a very wide circle of friends among the engineering fraternities of Cincinnati."

He was a member of the City Planning Commission, of Cincinnati, and when he left, he was made one of the two Honorary Members of the Engineers Club of Cincinnati.

As Professor Braune had impressed Dean (now President) Schneider with his personality and experience, so he impressed President H. W. Chase, of the University of North Carolina, when they met while on a vacation in the North Carolina mountains. The Department of Civil Engineering was seeking a head at this time, and several candidates were under consideration. Professor Braune was not a candidate, but Dr. Chase was convinced that he was the man for the place, and in September, 1921, he became Professor of Civil Engineering and Head of the Department at the University of North Carolina.

In 1922 the several Departments of Engineering were co-ordinated to form the School of Engineering, and Professor Braune became the first Dean. He was responsible for introducing a modification of the Cincinnati plan of co-operative education and for greatly expanding all forms of engineering work at the University of North Carolina. When he came to the University, the Engineering Departments had a faculty consisting of five men of professional rank, which had been expanded to twelve when he died. Equal expansion had taken place in curricula, number of students, and equipment. Dean Braune had a most charming personality which endeared him to students and gave him marked opportunities to exercise his abilities in university affairs and in municipal and social organizations.

"As a teacher in the Engineering School, he was possessed of a quiet dignity that was always mellowed by a spirit of cheerfulness and a God-given sense of humor. He possessed that fine quality of being commanding without being dictatorial, and of being familiar without breeding contempt. His classes were always pleasant discourses upon subjects with which he was so familiar and those which he loved so well. He was academic, yet practical, with many a story to impress upon the student mind the application of theory to actual practice.

"As great as was Dean Braune's ability as a teacher, he stands forth more vividly as a true friend and trusted adviser. He considered no problem of the student too trivial to warrant his time and attention, and there was no problem for which he could not effect a solution. To him, there were no differences of class. All shared his confidence from Freshmen to Graduate, and all had for him the greatest love and admiration. He inspired in all, a desire to work for the pleasures of accomplishment, and not a fear of punishment for work poorly executed. His interest was fatherly, and a pleasant smile and 'well done' from him was more to be desired than the highest of grades."[2]

Dean Braune was not only most sympathetic in promoting engineering research, but contributed notably to experiments in earth pressures at both the Engineering Schools with which he was connected. He initiated the largest scale culvert experiment yet undertaken (in collaboration with Charles M. Upham, M. Am. Soc. C. E., Harold Janda, Assoc. M. Am. Soc. C. E., and the late William Cain, M. Am. Soc. C. E.), and the deflection tests made on the reinforced concrete bridge over the Yadkin River prior to its destruction.

He was active in the interests of the Society in North Carolina, as he had been in Cincinnati, and indeed all his life. He founded the Student Chapter at the University of Cincinnati (Braune Engineering Society) and that at the University of North Carolina, the William Cain Engineering Society, named after the late Professor Cain. Dean Braune was widely and favorably known in many parts of the South and his friends in North Carolina, Alabama, and Tennessee presented his name for Director of the Society in 1924. He was defeated for election by a very small number of votes by the late Paul H. Norcross, M. Am. Soc. C. E. Upon Mr. Norcross' death, soon after in the tragic *Norman* disaster, the Georgia Section of the Society most courteously urged the appointment of Dean Braune to succeed to the remainder of Mr. Norcross' term. This appointment was made, and Dean Braune served as Director from 1925 to 1927. It is of interest to note that the only other Director of the Society from North Carolina was Dean Braune's predecessor and collaborator, the late Professor Cain, of the University of North Carolina.

While a member of the Board of Direction, Dean Braune served as Chairman of the Student Chapter Committee in 1926-1927, and as a member of the Committees on Technical Procedure (1926) and on Research (1927). Later, in 1930, he served as a member of the Committee on Graded Schools. He was zealous in the performance of his duties as a member of the Board, and his associates were impressed by his earnest attention to matters under consideration. Jealous of the prestige of the Society, he was a supporter of its high standards, and a firm believer in its aims and activities. He earned the respect and esteem of his associates, and his delightful personal qualities endeared him to them all.

---

[2] Excerpt from address of T. M. Riddick, Representative of the Student Body at the presentation of a portrait of Dean Braune to the Engineering School of the University of North Carolina, on May 19, 1932.

Dean Braune was greatly admired and liked by the Faculty and students of the University, and the towns people of Chapel Hill, N. C. For many years he was a member of the Chapel Hill Board of Aldermen, a Vestryman of the Protestant Episcopal Church, and a member of many committees and boards of the University.

He had not been in good health for several years prior to his death, and when he suffered a violent attack of pneumonia, he was unable to throw it off, being ill only three days. He is survived by his widow, May Ida (Stoelker) Braune, to whom he was married on February 8, 1899, and his daughter, Anna.

He was a member of the Society for the Promotion of Engineering Education (Councillor, 1925-28), Phi Beta Kappa (honorary from Washington and Lee University), Sigma Xi, Tau Beta Pi, and (honorary) Engineers Club of Cincinnati.

Dean Braune was elected a Junior of the American Society of Civil Engineers on June 2, 1896, an Associate Member on September 4, 1901, and a Member on May 15, 1917.

HUGH BRODIE, M. Am. Soc. C. E.[1]

DIED MARCH 19, 1932

Hugh Brodie was born on July 12, 1871, near Mount Pleasant, Mich., of Scotch parentage. His father, a native of Scotland, came to Canada in 1854, where he taught school for three years. In 1857, he went to Michigan, and two years later entered a claim for a homestead. In 1866, he married Jennie McLeod, a pioneer school teacher of Central Michigan.

Hugh Brodie received his early mathematical training from his father, a man of keen and active mind. From his mother, who conducted the first art studio in Mount Pleasant, he inherited an appreciation of the beautiful.

Mr. Brodie grew to young manhood on the farm where he was born, enduring the inconveniences and hardships of a pioneer homestead. When he was about eighteen years old he suffered an illness involving a major operation. His health was so impaired following this experience, that he found it necessary to go to a milder climate. In 1889, accompanied by his mother and a sister, he went to Florida, where he spent several years. There he gradually regained his health, but was left with defective hearing and a permanently weakened heart. Against these physical handicaps he had to work throughout the remainder of his life.

While convalescing in Florida he spent as much time as possible in such schools as were available, and in other studies. He spent one year alone with his books in the solitude of the Florida pine forest, reviewing all his previous school work. He then entered the Florida State Teachers College, completing the course in 1897. The next few years were spent in teaching in the Florida public schools.

---

[1] Memoir prepared by C. O. Carey, M. Am. Soc. C. E.

From January, 1900, to January, 1902, Mr. Brodie was in the employ of the Seaboard Air Line Railroad Company as Tapeman, Rodman, Instrumentman, Inspector, and General Foreman of Construction. From January, 1902, to July, 1903, he was Assistant Superintendent of the Talantic Lumber Company. Through this experience he became interested in engineering and decided to obtain an engineering education. Although he was much older than the average student entering college, he enrolled at the University of Michigan, Ann Arbor, Mich., as a freshman in the fall of 1903, and was graduated in 1907 with the degree of Bachelor of Science in Civil Engineering. In 1914, he received the degree of Civil Engineer from his Alma Mater.

In the fall of 1908 Mr. Brodie became Instructor in the Department of Geodesy and Surveying in the University of Michigan. In 1914, he was made Assistant Professor, and, in 1925, Associate Professor, which rank he held at the time of his death.

A paper[2] entitled "Report on a Series of Tests on Concrete Columns Reinforced with a Spiral of Steel," by Professor Brodie, as co-author with C. G. Wrentmore, M. Am. Soc. C. E., and the writer, was presented to the Society at its meeting on March 18, 1914.

From August, 1918, to February, 1920, Professor Brodie was on leave of absence from the University, and, with a group of American engineers, with Joseph Ripley, M. Am. Soc. C. E., as Chief Engineer, was engaged in surveys and hydrographic investigations along the Grand Canal and Yellow River, in China, for the Grand Canal Improvement Board, at Tientsin. In this work Professor Brodie had charge of parties on topographic surveys along 120 miles of the Grand Canal, and the survey of dikes and flood conditions on about 250 miles of the Yellow River.

Professor Brodie was a lover of Nature, and enjoyed life in the open. During the years spent in Florida he traveled through all parts of the State. On these trips he saw many of the old Indian mounds, and became interested in prehistoric life. This interest he maintained throughout his life. He was a keen observer of wild animal life, and enjoyed the study of plants and trees.

He was a tireless worker, unsparing in his efforts to accomplish the task in hand. In his work as a teacher, he gave his time without reserve to his students, spending many hours outside the classroom discussing their problems with them.

He had a kindly, sympathetic nature, was always deeply concerned about those who were in trouble or distress, and willing to lend a helping hand to those in need. He maintained an uncompromising attitude when he thought an important principle was involved. He sometimes led those who did not know him well to feel that he was harsh and unyielding. His honesty of purpose and his keen desire to be fair were appreciated by those who knew him intimately.

Professor Brodie was not married, but his home in Ann Arbor during the latter years of his life provided living accommodations each year for one or more students who needed financial aid to continue their university work.

---

[2] *Transactions*, Am. Soc. C. E., Vol. LXXVII (1915), p. 97.

He was a member of the Michigan Engineering Society, the University Club, and the Ann Arbor Golf and Outing Club.

Professor Brodie was elected a Member of the American Society of Civil Engineers on October 14, 1929.

PAUL KING BUNN, M. Am. Soc. C. E.[1]

Died January 23, 1932

Paul King Bunn was born at Buffalo Grove, Iowa, on August 6, 1891. His parents, Burris Harbis Bunn and Florence Adelia Bunn, were sturdy Americans, and Mr. Bunn received a sound heritage, both mentally and physically. His parents were residents of Rush Center, Kans., but, later, moved to La Crosse, Kans., and Mr. Bunn was educated in the grade schools of both places, but was graduated from the La Crosse High School. He then entered the University of Kansas, at Lawrence, Kans., from which he was graduated in 1914, with the degree of Bachelor of Science in Civil Engineering.

Mr. Bunn's first engineering work was with the Interstate Commerce Commission, Bureau of Valuation, Western District, where he served as Junior Civil Engineer from July, 1914, to October, 1917. He resigned this position to enlist in the Army as a Private. He was assigned to Company A, 29th Engineers, and was sent to France with his regiment after a short period of training. Mr. Bunn served nineteen months in France, most of which time was spent on the advanced line. During this period he was successively advanced in rank and was honorably discharged as a Second Lieutenant of Engineers in January, 1919.

After his discharge from the Service, Mr. Bunn again entered the employ of the Interstate Commerce Commission and served as Senior Civil Engineer until November, 1919. He then was engaged, successively, as follows: November, 1919, to August, 1920, Assistant Engineer, Leavenworth County, Kansas; August to November, 1920, Resident Engineer, Wyandotte County, Kansas; November, 1920, to January, 1922, Resident Engineer, Leavenworth County, Kansas, on concrete roads and bridges; and January to March, 1922, Resident Engineer, for V. V. Long and Company, on paving and sewer construction.

In March, 1922, Mr. Bunn entered the employ of The Missouri Valley Bridge and Iron Company, Contractors, of Leavenworth, Kans., with which Company he was engaged continuously until his death on January 23, 1932. During this time he was promoted, successively, from Timekeeper to Foreman to Field Engineer, and to Superintendent of Construction, which position he held at the time of his death.

It was in this position that he did his best work. He was well fitted for the job, being possessed of a fine constitution, and a calm, philosophical, well balanced mind. A hard worker himself, he won the good will and hearty co-operation of all his subordinates as well as the high esteem of his employers.

---

[1] Memoir prepared by E. H. Connor, and L. M. Bush, Members, Am. Soc. C. E.

As Superintendent for the Contractors, his work was quite varied and extensive, and Mr. Bunn became known as a builder of foundations and for caisson construction. He constructed the substructures of highway and railroad bridges across many of the large and difficult rivers of the Southwest, including the Cimarron at Guthrie, Okla.; the Brazos, in Texas; the Gila, at Yuma, Ariz.; the Canadian, at Canadian, Tex.; the Mississippi, at Louisiana, Mo., and at Cairo, Ill.; and the Missouri, at St. Charles, Mo.

While engaged on the Louisville and Nashville Railroad Bridge across the Ohio River, at Henderson, Ky., Mr. Bunn was stricken with appendicitis and died on January 23, 1932, after an illness of only one week. He passed away in the prime of life.

His was a valuable experience, with excellent prospects of greater usefulness in his chosen line of work. His many lovable, generous qualities endeared him to all his associates, and his upright, fair, and square treatment of his men and of all who came in contact with him, made them feel a deep loyalty and respect for him. They have lost a good friend. His love and thoughtfulness in all his travels and labors for the comfort of his invalid mother, Mrs. Florence A. Bunn, who still lives at La Crosse, was characteristic of the man.

He was married on January 12, 1929, to Elizabeth Gray Dickison, at Louisiana, Mo., who survives him. Their only child, Paula Elizabeth, was born on April 5, 1932, nearly ten weeks after Mr. Bunn's death. He is also survived by a sister, Mrs. Z. L. Hall, of La Crosse, Kans.

Mr. Bunn was elected an Associate Member of the American Society of Civil Engineers on March 16, 1925, and a Member on May 25, 1931.

HECTOR ROBINS BURROUGHS, M. Am. Soc. C. E.[1]

Died December 21, 1929

Hector Robins Burroughs was born at Penns Manor, Pa., on August 1, 1878, the son of Henry Boswell, and Rebecca Wooley (Robins) Burroughs. In 1902, he received the degree of Civil Engineer from the National Institute of Technology and, later (1910), successfully completed a post-graduate course in Advanced Structures at the Brooklyn (N. Y.) Polytechnic Institute.

In 1901 and 1902, Mr. Burroughs was employed as Draftsman on structural details with the Post, McCord, and Jackson Iron Works of New York, N. Y. The following year he went to San Francisco, Calif., where he was engaged as Engineer for the Pacific Rolling Mills, in charge of drafting, estimating, and shop work for machines, bridges, and buildings. He also designed and supervised complete railroad turn-outs, cross-overs, crossings, yards, and special track work.

During a number of subsequent years he was engaged in various capacities among which are included the following: 1905 to 1906, Assistant Engineer for the Pacific Construction Company of San Francisco, designing and estimating steel and concrete-steel bridges and buildings (it was at this time that the great earthquake occurred in California and the reconstruction work arising therefrom gained for Mr. Burroughs a very valuable experience); 1906 to 1907, Checker and Draftsman with Frank B. Gilbreth, of New York, on drawings for the McGraw Building of that city; 1907 to 1908, Structural Engineer for the Southern Pacific Railroad Company; 1908 to 1909, Engineer and Superintendent of Buildings in charge of design and construction, for the Pacific Fruit Express Company, with headquarters at Las Vegas, Nev.; 1909 to 1910, Assistant Engineer in the San Francisco Office of Messrs. Sanderson and Porter, of New York, in charge of construction of a sub-station building, Bay Shore, Calif.; 1910 to 1911, Designer and Estimator, Office of Engineer of Structures, New York Central and Hudson River Railroad Company, engaged on bridges, viaducts, towers, retaining walls, etc.; and July, 1911, to January, 1912, Assistant Engineer, the Concrete Steel Engineering Company of New York, designing, estimating, and reviewing concrete-steel bridges.

---

[1] Memoir prepared from data on file at the Headquarters of the Society and from information supplied by the H. Robins Burroughs Co., Inc., New York, N. Y.

In January, 1912, Mr. Burroughs was engaged as Assistant to S. C. Weiskopf, M. Am. Soc. C. E., soon thereafter becoming a member of the firm known as Weiskopf and Burroughs, Consulting Engineers, of New York City. Many important buildings in and about New York were designed and built by this firm in succeeding years. Later, beginning in 1920, Mr. Burroughs conducted an independent practice of Consulting Engineering. It was during this period that he designed the steel structures and acted as Consulting Engineer on about seventy-five buildings in the vicinity of New York (among which was the Roxy Theater), and in other parts of the United States as well.

Also, during this period, he became interested in tennis court construction, this interest culminating in his development of the Bursco Fast Drying Tennis Court. At the time of his death he had perfected this surfacing and had a patent pending on it.

Mr. Burroughs was deeply interested in the Army and for a number of years belonged to the Engineers' Reserves. At the time of his death, he was a Major in the 368th Engineers. During the World War, he served with the Second Corps Engineers in Washington, D. C., and was employed on the construction of a torpedo plant.

He was a member of the American Institute of Consulting Engineers, the American Society of Military Engineers, the American Concrete Institute, and the American Society for Testing Materials. He was also a member of the Masonic Fraternity, and of the First Presbyterian Church, of Trenton, N. J. His recreations were tennis, squash, golf, and motoring, and he held membership in the Army and Navy, and the Crescent Athletic Clubs.

His high professional character and integrity made him a very valuable member of the Engineering Profession. He was killed in an automobile accident on December 21, 1929.

Mr. Burroughs was married in September, 1917, at Boston, Mass., to Mary Jane Owen, who survives him.

His death was a distinct shock to the large number of friends whose respect and genuine liking he had commanded because of his affability and genuine fineness of spirit. A credit to his profession, his outside interests were varied as witnessed by his Army and Masonic connections and his sporting activities. With regard to the latter, he was well known in both tennis and squash circles and, at the time of his death, was just beginning to get the fullest enjoyment out of a country place in Rhode Island, which gave him and his friends ample opportunities to satisfy all their sporting instincts.

Mr. Burroughs was elected a Junior of the American Society of Civil Engineers on March 3, 1908, an Associate Member on September 6, 1910, and a Member on July 7, 1915.

GEORGE RAYMOND CAMPBELL, M. Am. Soc. C. E.[1]

DIED APRIL 1, 1932

George Raymond Campbell was born on June 22, 1874, at The Dalles, Ore. He was the son of William Ellis Campbell and Sarah (Angell) Campbell, early pioneers of Oregon, his mother having come with her parents by covered wagon from Iowa to Oregon in 1851. On his father's side, he was a descendant of a Seventeenth Century settler from Scotland, and on his mother's, of the Thomas Angell who settled in Rhode Island, and who was one of the fifty-four associates who received land grants of property from Roger Williams, which later became the site of Providence.

After completing High School at The Dalles, Mr. Campbell worked his way through the University of Oregon, from which he was graduated in 1901, with the degrees of Bachelor of Science and Civil Engineer. He was the first man to receive the degree of Civil Engineer from that institution. While attending the University he was active in football and in debating societies.

For several years after his graduation, Mr. Campbell was in private practice at The Dalles, and made surveys and designs for irrigation, power, and storage projects along the Columbia River. In 1902, he was Engineer in Charge of three field parties on the survey of the Quinaielt Indian Reservation for the United States Department of the Interior. As such, he prepared the records and topographical maps and made the preliminary designs and report for drainage.

From 1904 to 1910, he was Senior Member of the firm of Campbell and Campbell, Civil Engineers, with offices in Spokane, Wash., and in this capacity served as Consulting, Designing, and Contracting Engineer on hydraulics, reinforced concrete, irrigation, power, and drainage problems. In 1906, he was engaged as Engineer in Charge of three field parties in surveying the Yakima Indian Reservation in the State of Washington for the Department of the Interior. This great area was surveyed in accordance with the old treaty stipulations on the long disputed boundary, and resulted in a $2 500 000 suit being decided in favor of the Government. Mr. Campbell prepared the reports and topographical maps, and make the preliminary report on the irrigation of that fertile but arid district.

---

[1] Memoir prepared by Carroll R. Campbell, U. S. Insp., Glasgow, Mo.

While in the Bridge Department of the City Engineer's Office, of Spokane, Mr. Campbell made the preliminary design for the Latah Creek (reinforced concrete) Bridge, checked the arches, and determined the unit stresses of the final design. He also made structural designs of truss and girder bridges, and was engaged on other municipal problems, including the Sprague Avenue Fill.

In 1912, deciding to enter the Government Service, Mr. Campbell passed the first two available Federal examinations, that for full grade United States Civil Engineer, and for United States Surveyor. For several years, he was U. S. Surveyor for the Department of the Interior on various surveys, being transferred in 1915 to the Federal Office at Olympia, Wash. Among his assignments were the hydrographic survey of the Nooksack River and Bellingham Bay, and the restoration surveys of Lumni and Swinomish Indian Reservations. In June, 1917, he was commissioned as Captain, in the Engineer Section, of the Officers Reserve Corps, and received training at the Presidio, in San Francisco, Calif. He was honorably discharged before being assigned to duty.

As United States Cadastral Engineer, Department of the Interior, in 1918 and 1919, Mr. Campbell made mine examinations and surveys, and hydrographic determinations of river channels and islands in Pend Oreille, Skagit, Snake, and Columbia Rivers; and located highways and Government lighthouses on the islands of San Juan Channel. He resigned in 1920, to accept a position with the Washington State Reclamation Service. He was in field charge of soil surveys and diking, drainage, and river and ocean control investigations for the State.

Since 1922, while engaged in private practice as a Consulting Engineer on irrigation problems, Mr. Campbell devoted much of his time to the running of his apple orchard in Yakima, Wash. One of his last engineering jobs was the supervision of steel erection on a four-story reinforced concrete cold-storage plant for the Yakima County Horticultural Union, of which he was a member.

In apparently sound health, his sudden passing in his sleep on April 1, 1932, was a great shock to his family and friends.

Few men knew the Pacific Northwest as did Mr. Campbell. His work as an engineer had taken him into the most inaccessible mountain areas. As a young man, earning his way through college by working in the summer months as a Surveyor in the mountains of Eastern Oregon, and, later, in private practice and as a Government Engineer, he saw and contributed to the development of the Pacific Northwest as his ancestors in Colonial times did to that of the Atlantic seaboard. It was natural that his principal hobby was the hunting of big game. His specimens of elk, deer, and bear, are outstanding trophies.

His interest in all phases of engineering was unlimited, as his excellent library of technical books and his bound volumes of engineering magazines and transactions of technical societies testify. In his spare time he could always be found inquiring into some engineering problem, often for its abstract interest alone. His associates in the profession and companions on the hunt respected him for his purposeful will and buoyant good spirits. Mr. Campbell was noted for his exemplary character and for his ability to get along with all kinds of men. He was a member of the Masonic Fraternity for thirty years, the Scottish Rite, and the Shrine.

On November 15, 1905, he was married to Lena Liebe, of The Dalles, Ore., who, with three children, Carroll R., Waldemar B., and Vera Lenoire, survives him. He is also survived by his 81-year old mother, Mrs. Sarah (Angell) Campbell, and by three brothers, Roy T., a U. S. Cadastral Engineer; Rex R., and Fred E. Campbell.

Mr. Campbell was elected an Associate Member of the American Society of Civil Engineers on August 31, 1915, and a Member, on April 21, 1920.

EDWARD CARLOS CARTER, M. Am. Soc. C. E.[1]

Died December 23, 1930

Edward Carlos Carter was born at Waverly, Ill., on January 11, 1854, the son of George and Louisa J. (Smith) Carter.

At the age of fifteen, he joined a surveying party of the Jacksonville, South Eastern, and North Western Railroad Company (later, a part of the Chicago, Burlington, and Quincy Railroad Company), on a line extending from Jacksonville to Virden, Ill. At intervals during the next three years, he worked as Levelman and Assistant Engineer on various railroads. In 1872, he entered Rensselaer Polytechnic Institute, at Troy, N. Y., from which he was graduated in June, 1876, with a degree of Civil Engineer.

Subsequent to his graduation, Mr. Carter's professional career was as follows: 1877 and 1878, Principal Assistant Engineer with the United States Engineers on the Mississippi River; 1878 and 1879, Assistant on Location, Chicago and Alton Railroad, Kansas City Division, and Assistant in Charge of Construction on the Blue Springs Division; 1879 and 1880, Assistant Engineer of Construction on the Indianapolis, Decatur, and Springfield Railroad; 1880 to 1882, Assistant Engineer of Maintenance, 1882 to 1884, Resident Engineer on the Middle Division, and 1884 and 1885, Principal Assistant Engineer on the Wabash, St. Louis, and Pacific Railroad; and 1885 to 1887, Assistant Engineer of the Detroit Bridge and Iron Works, at Detroit, Mich.

In 1887, Mr. Carter became Principal Assistant Engineer of the Chicago and North Western Railway Company, at which time, the late Mr. Horace G.

---

[1] Memoir prepared by a Joint Committee of the Society and the Western Society of Engineers, consisting of Charles F. Loweth, Past-President, Am. Soc. C. E., Bion J. Arnold, M. Am. Soc. C. E., George W. Hand, Assoc. M. Am. Soc. C. E., and Chester T. Dike, M. W. S. E.

Burt was Chief Engineer. He held this position during the remainder of the time that Mr. Burt was Chief Engineer and also during the tenure of Mr. Burt's successor, the late Mr. John E. Blunt. As Principal Assistant Engineer, Mr. Carter was in general charge of maintenance and construction. In 1899, he became Chief Engineer and retained this position until June, 1914, when, at the age of sixty, he decided to relinquish the active duties of his office and devote the remainder of his life to travel, study, and the practice of his profession as a Consulting Engineer.

In May, 1914, the City Council of Chicago, by ordinance, created the Chicago Railway Terminal Commission, consisting of municipal officials and others. In July, this Commission started abroad to study the railway terminals of other cities, and a few men, each expert in his field, were invited by the Commission to accompany it. Mr. Carter, among others, was selected to represent the steam railways.

Before sailing, however, the party visited Toronto, Ont., and Montreal, Que., Canada, Boston, Mass., and New York, N. Y. The Commission and its guests then went abroad and visited Liverpool, Manchester, and London, England, and Paris, France, where they were officially entertained. The itinerary called for an extensive trip through European countries, and the Commission was to leave Paris for Frankfort, Germany, on July 29, but the declaration of war by Austria against Servia on July 28, made a change in its plans necessary, and the party returned, *via* Brussels and Antwerp, Belgium, to London, and thence to the United States.

During Mr. Carter's service of more than twenty-seven years with the Chicago and North Western Railway Company, he manifested a broad and continuing interest in all phases of railroad construction, maintenance, and operation. He was a member of one of the earliest committees of the American Railway Association having to do with train rules. Early in his career he became interested in train signaling and was one of the first railroad engineers to give this important matter the study and attention it deserved. It was on his recommendation that the Chicago and North Western Railway Company, in preparation for handling the heavy traffic during the World's Columbian Exposition in 1893, installed extensive automatic block signals and interlocking plants in and near Chicago, including an extensive plant at the Chicago Terminal, which embodied the principles he had evolved, thereby contributing a marked advance in the art of signaling. Mr. Carter was a pioneer in promoting the use of semaphore signals operating in a quadrant above the horizontal, on a principle which had not been previously utilized, but which is now almost universal. He also brought about improvements in signal lighting, both in respect to the use of colors and their combinations and also in the details of lamps and lenses. In 1901, he invented a continuous-rail derail which obviated the troubles experienced with the common switch-point derail then in use. The principle he developed has been largely utilized in derails since that time, and a large number of derails of the type he invented are still in use.

While Chief Engineer of the Chicago and North Western Railway, Mr. Carter had responsible charge and direction of a large amount of new construction and improvements carried on by that Company, which included the location and construction of about 1 400 miles of new line; the major portion of the second track across the State of Iowa; the Boone Viaduct over the Des Moines River Valley, constructed in 1901—a bridge more than $\frac{1}{2}$ mile long and 185 ft. high, which at the time it was built was a most notable structure; a bridge over the Missouri River at Pierre, S. Dak., completed in 1907; a double-track bridge over the Mississippi River at Clinton, Iowa, completed in 1909; and many other large and noteworthy structures. It was under his direction and supervision that the Company planned and constructed its modern passenger terminal in Chicago, which was completed and put in operation in 1911 at a cost of $25 000 000. During the years that he was Chief Engineer of the North Western Railway, that Company also carried out track-elevation projects in the City of Chicago alone, which cost more than $12 000 000.

Mr. Carter always manifested a broad and active interest in all engineering matters. He was one of the oldest members of the Western Society of Engineers, of which he was Vice-President in 1892 and President in 1905. In 1929, in recognition of his long membership and notable accomplishments in engineering, he was made an Honorary Member of that Society. He was also a member of the Special Committee on Standard Rail Sections of the American Society of Civil Engineers, a member of the Railway Guild of New York City, the Union League Club, of Chicago, the Glen View Golf Club, and the Camp Fire Club.

He was married, in 1880, to Fannie G. Fairbank, of Jacksonville, Ill. Mrs. Carter, with their three children, Mrs. C. M. Bell, Edward F. Carter, and Paul E. Carter, survives him.

Mr. Carter was elected a Member of the American Society of Civil Engineers on April 4, 1888. He served as a Director of the Society from 1901 to 1903.

WILLIS CHIPMAN, M. Am. Soc. C. E.[1]

Died January 3, 1929

Willis Chipman was born in Elgin, Ont., Canada, on October 1, 1855, the son of Lewis Chipman of English lineage dating from the time of William the Conqueror. His mother was Abigail Jane (Delong) Chipman, the daughter of Jesse Delong of Elgin. It is recorded that the first member of the family to seek a home in America was John Chipman, who sailed from Barnstable, Devon, England, when he was 17 years of age and landed at Boston, Mass., on July 14, 1631.

Mr. Chipman attended the public school, at Athens, Ont., and the Weston, Ont., High School, later entering McGill University, Montreal, Que., Canada, from which he was graduated in 1876, with first rank honors in Civil and Mechanical Engineering. Following his graduation he became a teacher in the High School, at Napanee, Ont., Canada, serving as Mathematical Master on the Staff. He next entered the service of the Geological Survey of Canada, and afterward served as Assistant Engineer on the construction of the Toronto, Ont., Water-Works.

---

[1] Memoir prepared from information on file at the Headquarters of the Society.

Mr. Chipman then entered the profession of Land Surveying and became articled to Mr. G. B. Abrey, of Manitoulin, Ont., Canada, for one year, during which he was engaged on surveys in the then Canadian Northwest Territories. He obtained his commission as Dominion Land Surveyor on May 21, 1881, and was granted his commission as Provincial Land Surveyor for Ontario on October 4, 1881.

In November, 1881, Mr. Chipman began his practice, in Brockville, Ont., Canada, as a Land Surveyor and Civil Engineer, serving also as City Engineer for that city. For several years he carried on the dual practice, as well as, from January, 1889, to January, 1891, a partnership with the late Lieut.-Col. B. J. Saunders.

Convinced of the importance of old records in surveying work, Mr. Chipman acquired the field notes of many by-gone surveyors, and these are now in the hands of his surveying successors in Brockville. During his practice in Land Surveying, he served with the Department of the Interior from May to October, 1883, in surveys in the Northwest Territories. He also made the following sub-division surveys for the Department of Crown Lands (Ontario): 1884, Township of Mulock; 1886, Township of French; 1886, Township of Stewart; and, in 1890, the Township of Lockhart, all in the District of Nippissing. A plan of the Town of Brockville was prepared by him in 1883 and 1884.

Realizing the disadvantages both in regard to the members of the Profession as well as to the public—their clients—arising from the lack of cohesion among Land Surveyors, Mr. Chipman undertook the task of organizing the surveyors for Ontario. After continued correspondence, a meeting of representative surveyors was held in Toronto, Ont., Canada, on February 25, 1886, and the Association of Provincial Land Surveyors was formed, of which Mr. Chipman was Secretary-Treasurer; he continued in this office until 1890; in 1892, the Association became incorporated. Mr. Chipman held the office of Vice-President in 1895 and that of President in 1896, and, until his death, he continued his activities for the Association. To meet the requirements of his increasing practice, Mr. Chipman closed his Brockville Office in 1894, and removed to Toronto.

In his field of engineering, he won a Dominion-wide reputation, particularly in the branches relating to water-works and sewerage, his practice extending from Halifax, N. S., to Victoria, B. C., Canada. In 1893, he served as President of the Association of Health Officers of Ontario, and he also served as a member of the Commission appointed in 1911 to inquire into the situation of the collapse of the Toronto Water-Works. Among his published articles on

Sanitary Engineering are: "Ontario Waterworks System"[2]; "The Separate System of Sewerage in Ontario"[3]; "London Sewerage System"; and "Oakville Waterworks Auxiliary". He is regarded as the originator of the separate system for sanitary and storm-water sewers in Canada.

On April 1, 1910, Mr. George H. Power, who had acted as his Assistant from September, 1901, became Mr. Chipman's partner, and the firm continued in practice in all the Provinces of Canada as Chipman and Power until October 1, 1924.

In his quest for further information in his calling, Mr. Chipman visited the New England States, in 1885, to inspect and study water-works and sewerage problems; and in February and March, 1900, he investigated water-works, sewerage, and sewage disposal systems in England and Scotland. In 1891, he made a study of the sanitary systems of Denver, Colo., Seattle, Wash., and San Francisco, Calif.

Among the appointments and offices held by Mr. Chipman in connection with his Profession may be mentioned his service for three terms on the Council of the Canadian Society of Civil Engineers. During the transition of that body to the Engineering Institute of Canada, he was one of the prominent members of the Committee of Fourteen Engineers that was charged with the drafting of the Constitution and By-Laws. Later, he was one of the most active members of the Committee to which the drawing up of the bill for the organization of the Professional Engineers of Ontario was entrusted. The Engineers' Club of Toronto is another professional body which owes its inception and growth largely to the initiative and energy of Mr. Chipman. He was also a member of the American Waterworks Association throughout his active career.

Aside from his activities in professional matters, Mr. Chipman devoted much time to research in the history of the Province of Ontario, particularly that of Leeds County, and, as a member of the Ontario Historical Society, he made valuable contributions to its *Proceedings*. He also made a study of ornithology and was well versed in the subject. His Alma Mater meant much to him, and he was a member of the Graduates' Society of McGill University and a frequent contributor to its quarterly publication, *The McGill News*. In religion, Mr. Chipman was of the Anglican faith and, in politics, a Liberal.

Mr. Chipman was married on May 5, 1880, to Angeline Denison, who died in 1883 leaving a son, Harry D., now of Rhodesia, South Africa, and a daughter, Julia Angeline, of Toronto. He later was married to Elizabeth Bray Finlayson, the surviving children being Gertrude Elma, the wife of Charles W. Pennington of Dundas, Ont., Canada, and Lucy Kathleen, the wife of Arthus S. Runciman, of Montreal West. He was again married to Edith Venton Scott, who survives him.

Despite increasing weakness through illness Mr. Chipman continued to carry on as Chairman of the Biographical Committee of the Ontario Land

---

[2] *Canadian Engineer*, 1898.

[3] *Transactions*, Canadian Soc. of Civ. Engrs., January–December, 1897–98, Vol. 11–12, p. 163.

Surveyors' Association almost to the time of his death. He was interred in the old family plot at Brockville. Fittingly, his ring denoting "The Calling of an Engineer," was buried with him.

Mr. Chipman was elected a Member of the American Society of Civil Engineers on June 6, 1888.

JOHN CHRISTIAN VALDEMAR CHRISTENSEN, M. Am. Soc. C. E.[1]

Died June 16, 1931

John Christian Valdemar Christensen was born in Copenhagen, Denmark, on March 2, 1881, the son of Lars and Karen (Jorgensen) Christensen.

Mr. Christensen was graduated from the Polytechnic College of the Royal University at Copenhagen, with the degree of Civil Engineer, in January, 1903, and began his engineering career in May of that year as Draftsman with the Pittsburg, Shawmut, and Northern Railway Company, at Olean, N. Y. He remained in this position until August, 1903, when he went to Chicago, Ill., as Draftsman for the Chicago, Rock Island and Pacific Railroad Company. In June, 1904, he entered the employ of the Chicago and Eastern Illinois Railroad Company as Draftsman and, in December of the same year, he went in the same capacity to the Chicago Southern Railway Company, at Chicago.

In March, 1905, Mr. Christensen returned to the Chicago and Eastern Illinois Railroad Company, in Chicago, and remained there until September, when he joined the Engineering Organization of the Detroit River Tunnel Company, at Detroit, Mich., as Designer of tunnel sections, retaining walls, and a highway bridge, and as Inspector on the driving of the tunnel headings. On the completion of this work in March, 1907, Mr. Christensen went to New York, N. Y., as Draftsman for the New York Central and Hudson River Railroad Company, where he remained until March, 1908. From March, 1908, until May, 1909, he was engaged in private business in Copenhagen, Denmark.

He returned to New York in May, 1909, and became Designer and Squad Chief on the design of steel, concrete, and timber railroad and highway bridges, in connection with the Electric Zone Improvements on the New York Central and Hudson River Railroad. Mr. Christensen remained with the New York Central until April, 1913, when he was made Designing Engineer for the Gulf, Florida, and Alabama Railway Company, at Pensacola, Fla., where he was in charge of the structural design for bulkheads, piers, pier-sheds, substructures, and superstructures for bridges and coffer-dams.

In August, 1916, Mr. Christensen returned to the New York Central and Hudson River Railroad Company as Designer and remained in that capacity until November, 1917, when he went to the Calco Chemical Company, at Bound Brook, N. J., as Designing Engineer in charge of plant alterations and extensions. He remained with the Calco Chemical Company until October, 1918, when he returned to New York City, as Engineer for The Terry and Tench Company, for which he had charge of the engineering work on the Stapleton Piers, Staten Island, for the City of New York, underpinning the Lincoln Memorial, at Washington, D. C., and some of the work in connection with the Bear Mountain Bridge across the Hudson River.

---

[1] Memoir prepared by John M. Belknap, M. Am. Soc. C. E.

In March, 1926, Mr. Christensen was appointed Structural Engineer for the Foundation Company, of New York City and from that time until December, 1927, he was in charge of the structural design for the shops of the Wabash Railroad Company, at Decatur, Ill., a new plant for the Goodrich Rubber Company, at Los Angeles, Calif., and harbor improvements for ports in Venezuela and Peru.

In December, 1927, he went to Cincinnati, Ohio, as Engineer of Structures for the Cincinnati Union Terminal Company and was in charge of all structural designs for the new Union Passenger Terminal until July, 1929, when he was made Engineer of Design. In this capacity Mr. Christensen had charge of the design of all bridge structures, track work, and buildings connected with the new Union Terminal, with the exception of the Station Building.

The design of the Western Hills Viaduct, which was built in connection with the Terminal improvements, and the solution of the intricate engineering problems pertaining to this structure, was one of his most important achievements as a member of the Engineering Staff of the Cincinnati Union Terminal.

Mr. Christensen was a Structural Engineer of rare ability, which, with his innate frankness and pleasing personality, made for him a host of friends who unite in mourning his death.

On May 1, 1909, he was married to Dika Adelaide Martensen who, with a son, Paul Christensen, and a daughter, Lily Christensen, survives him.

Mr. Christensen was elected a Member of the American Society of Civil Engineers on October 1, 1928.

ST. JOHN CLARKE, M. Am. Soc. C. E.[1]

Died May 22, 1931

St. John Clarke was born in Richmond, Va., on April 21, 1863, the son of Colonel John Graham Clarke and Lucy Selden (Macon) Clarke. His father, who was of English Quaker origin, was Chief of Engineers of Longstreet's Corps and, later, Chief of Engineers for General Robert E. Lee. Following the termination of the Civil War he was in charge of the reconstruction of railroads destroyed during Sherman's March to the Sea. On his mother's side, Mr. Clarke was of French Huguenot descent.

St. John Clarke began his professional career as a Rodman with the Richmond and Alleghany Railroad Company in June, 1881, being engaged on location until March, 1883, when he entered the employ of the Passaic Rolling Mills as Draftsman. He continued with that Company until the summer of 1888, during which period he gained a wide experience both in the designing room, shop, and erection fields of the then rapidly developing steel industry. As Resident Engineer for the Company, he had responsible charge of the steel work for the Washington Bridge over the Harlem River, New York, N. Y.

---

[1] Memoir prepared by George Hallett Clark, M. Am. Soc. C. E.

From June, 1888, to November, 1889, as Assistant Engineer for Hoffman and Bates of Portland, Ore., Mr. Clarke was engaged on the design and erection of combination bridges in the Northwest and also as a Transitman on a preliminary railroad survey from Portland to Tacoma, Wash. Returning east in November, 1889, he was employed as Draftsman in the office of the Engineer of Bridges of the Baltimore and Ohio Railroad Company until August, 1890, when he returned to the Passaic Rolling Mills as Assistant Engineer. As such he had charge in the office of most of the larger work and, at the same time, of the field work in erection of bridges, the most notable being the Macomb's Dam Bridge over the Harlem River, New York City.

From December, 1895, to June, 1896, he was with the Examining Department of the Department of Buildings, New York City, and from June, 1896, to May, 1900, in charge of the Estimating and Designing Department of Milliken Brothers, New York, preparing plans and estimates for high buildings and various other steel work.

While Mr. Clarke was with Milliken Brothers, his skill and thoroughness as a designing engineer brought him to the favorable notice of the late Theodore Cooper, M. Am. Soc. C. E., on whose recommendation he was selected for the responsible position of General Inspector of Designs in May, 1900, at the time of the organization of the Engineering Corps of the Board of Rapid Transit Railroad Commissioners, New York City, of which the late William Barclay Parsons, Hon. M. Am. Soc. C. E., was Chief Engineer.

The first subway constructed in the City of New York between May, 1900, and October, 1904, known as Contract No. 1 and, later, extended by Contract No. 2 into Brooklyn, N. Y., was built under a contract the drawings for which were typical and general in character. While the contract drawings were followed generally, the actual construction work required the preparation of a large number of "construction drawings" requiring the employment of a large force of designers and draftsmen, of which force St. John Clarke had personal direction and control. The expedition and economy with which the first subway was constructed in New York City, and its efficient operation and the low cost for maintenance of the structure, is a lasting monument to those responsible for its efficient planning.

Following the completion of construction and the beginning of operation of Contract No. 1 which extended through Manhattan from the City Hall to Van Cortlandt Park and to Bronx Park in The Bronx, Mr. Clarke resigned from the Board of Rapid Transit Railroad Commissioners, to become Chief Engineer of the Steinway Tunnel under the East River at 42d Street, which work he directed until its successful completion.

Following the completion of the Steinway Tunnel, Mr. Clarke engaged in general practice as a Consulting Engineer, his principal work being in the line of steel construction for buildings, tunnel methods, involving the use of compressed air, and details of design and analysis of stresses; for a time he was engaged in general contracting.

In addition to his professional activities, St. John Clarke was notable as a citizen in the community in which he spent the best years of his life. He became a resident of Bogota, N. J., in 1898, and at once took a special interest in the town in which he resided up to the time of his death. He became a member of the Board of Education in 1901 and was re-elected to the Board, serving until 1911. During his ten years of service, the latter eight were spent as President of the Board. Mr. Clarke was one of the founders and, for many years, an officer of the Bogart Memorial Church of Bogota, and as a Co-Trustee of the Bogart Estate had direct charge of the construction of the present edifice.

For several months prior to his death he took an active interest in grade elimination questions affecting the Town of Bogota, but did not live to see the results of his public service, which a month after his death resulted in the adoption by the State authorities of the plan which he had prepared in the interests of the community.

The following extracts from resolutions passed by official and other bodies, following his death, express the regard in which Mr. Clarke was held by his neighbors:

By the Mayor and Borough Council of the Borough of Bogota:

"*Whereas,* Mr. Clarke had given invaluable service during his thirty-three year residence in Bogota along religious and educational lines and to this Grade Crossing Elimination project, and in many other ways; therefore be it

"*Resolved,* That the Mayor and Council of the Borough of Bogota in meeting assembled on Thursday, May 28, 1931, express its deepest grief in the loss of such a staunch and stalwart citizen * * *."

By the Board of Education of the Borough of Bogota:

"*Whereas,* during his long residence in the Borough Mr. Clarke contributed generously of his time and his effort to the service of the public as a member of the Borough Council and as a member of the Board of Education, serving for eight years as the President of the Board; and

"*Whereas,* the wholesome influence which he exercised for so many years over public affairs in the Borough is sincerely recognized and will be long remembered,

"*Now Therefore Be It Resolved* that this Board of Education of Bogota hereby express its deep regret at his death, appreciating at the same time that the fine public service which he rendered is a far more fitting monument to his memory than any mere words which might be incorporated in a resolution of this nature and, in the hope that that service may act as an inspiration and a guiding light to the members of future boards, * * *."

By the Community Church of Bogota, N. J.:

"The Bogart Memorial Church learns with profound sorrow of the death on May 22, 1931, of Mr. St. John Clarke, one of its members and a former officer.

"Mr. Clarke moved to Bogota in 1898 and bore a prominent part in the early organization and administration of affairs of the Borough. He was a member of the Council, served eight years as President of the Board of Education, and was an officer of this Church from 1902 to 1906.

"He was one of the two Executors of the late Peter Bogart, whose benefaction made possible the construction of this church building. Through their fidelity and careful management they turned over funds to the officers of this Church for this building amounting to approximately twice the value of the properties before their stewardship; and this without fee to them."

Mr. Clarke was married in the fall of 1888 to Carrie S. Vanderlip, of Waverly, N. Y., a daughter of Stephen and Sylvinia Plummer Vanderlip, pioneer settlers of Tioga County, New York, who survives him. He is the father of John Graham Clarke (deceased), Charles Kennon Clarke, and Helen St. John Clarke.

An able, upright, and skillful Engineer, a genial and loyal friend, a useful and public-spirited citizen, who gave without compensation of his time and ability to the community in which he lived, St. John Clarke's career is both an example and an inspiration to his profession.

Mr. Clarke was elected a Junior of the American Society of Civil Engineers on September 5, 1888, and a Member on June 1, 1904.

JAMES RETZER COMLY, M. Am. Soc. C. E.[1]

Died October 6, 1931

James Retzer Comly was born to Harry R. and Beatrice (Seykora) Comly, on July 20, 1885, at Helena, Mont. He came from a family, of whom many were engineers, one, Henry Comly, having come with William Penn to the New World and having engaged in surveying and engineering in what is now the State of Pennsylvania. In 1893, Harry R. Comly moved with his family to San Diego, Calif., and from that time that city was the home of his son, James Retzer Comly.

Mr. Comly was graduated from the San Diego High School, in 1902, in the Scientific Course, and immediately entered the engineering field. His first work took him into Northern California and the Great Northwest where he held positions with the United States Reclamation Service, Bay Shore and Pacific Railroad Company, Peoples Water Company, and the Great Northern and the Southern Pacific Railroad Companies. During this period, covering nearly seven years of his early work, he spent his spare time studying and reading, and fitting himself for the Civil Engineering Profession.

In 1910, Mr. Comly became Locating and Constructing Engineer with the San Diego County Highway Commission, the first Highway Commission formed in the State of California.

In 1911, he became Assistant City Engineer of San Diego, and for the next four years was engaged in designing various municipal structures for water, harbor, and street and highway developments. Among the outstanding structures designed by Mr. Comly during this period were the Georgia Street Bridge across University Avenue, with its extensive retaining walls; the Seventeenth Street Bridge across E Street, and the Woolman Avenue Bridge. During this period he also made the first detailed survey of the water-front and San Diego Bay for a comprehensive study for future harbor development.

---

[1] Memoir prepared by Paul R. Watson, M. Am. Soc. C. E., and George Butler, Assoc. M. Am. Soc. C. E.

In 1915, he was engaged in private practice along engineering lines. In 1916, he was employed by the Sweetwater Company to design repairs of damage to the Sweetwater Dam and Distributing System occasioned by the heavy floods of that year.

From 1917 to 1920, except from January to November, 1918, during the World War, Mr. Comly was employed as Assistant Engineer by the San Diego and Arizona Railway Company, in charge of heavy mountain railroad construction. Later, he was put in charge of maintenance and valuation.

In January, 1918, Mr. Comly was commissioned a First Lieutenant in the Engineer Officers' Reserve Corps, and was assigned to the organization and training of Engineer Troops. He organized and commanded Company K, Seventh Engineers Training Regiment, and Company C of the Seventy-sixth Engineers. At the end of the World War he returned to San Diego.

In 1920, he again entered the employ of the City of San Diego as Senior Draftsman in the City Engineer's Office, devoting his time to study and investigation relative to water supply, flood control, harbor work, streets, and bridges. It was during this period that he suggested to the City Officials that some study be made along the lines of city planning, and he drew up a tentative plan in conformity with his ideas. Mr. Comly was one of the first to realize that it would be only a short time before through and heavy traffic would have to be by-passed around the business district on account of congestion and urged the City of San Diego to purchase rights of way while the land was still comparatively cheap and unoccupied, in order to provide for this contingency. This really inaugurated city planning in San Diego.

In 1922, he was engaged by the Spreckels Companies, of San Diego, to supervise the construction of the many buildings they were having built at this time, such as the San Diego Hotel and the Mission Beach Bath House.

From 1924 to the time of his death, Mr. Comly was engaged in private engineering practice. His chief activity during this period consisted of the design of municipal works connected with the laying out and development of high-class residential districts, such as La Jolla Country Club Estates, Ludington Heights, and Muirlands. He was also employed in numerous cases as Consulting Engineer in regard to water development, highways, and other work of a municipal character, and in this capacity rendered valuable service to the San Diego City Planning Commission.

Mr. Comly possessed marked ability to anticipate the engineering needs of the future, as shown by his endeavors to persuade the City of San Diego to adopt comprehensive plans for harbor development and city planning. In recent years, the wisdom of his ideas has been realized and many of his suggestions have been adopted. Mr. Comly was always painstaking in his work and was never satisfied until he had developed the problem to the utmost nicety.

The outstanding quality in his professional life was his high ideals of professional ethics. On account of these high ideals, he gained the respect of all those for whom he worked, as well as those with whom he was associated in his work.

Mr. Comly always took an active interest in the local affairs of the Society. He became a member of the Los Angeles Section shortly after its organization and, later, became active in the organization of the San Diego Section, of which he was a Charter Member and a Past-President.

His chief recreations were rowing and swimming and whenever he could spare the time from his professional work, he could be found at the San Diego Rowing Club. It was rarely that any water sports event took place without his presence, and especially outstanding was the frequency with which he officiated at aquatic meets.

Mr. Comly was a member of the San Diego Rowing Club and the San Diego Athletic Club. He was active in the Shrine Patrol and other Masonic organizations, and was a Past-President of the Local Chapter of the Sons of the American Revolution.

He was unmarried and is survived by a brother, Harry Comly, Assoc.M. Am. Soc. C. E., of Redding, Calif., and a sister, Cora Hornbuckle Comly, of San Diego.

Mr. Comly was elected an Associate Member of the American Society of Civil Engineers on April 2, 1913, and a Member on October 11, 1920.

HENRY ST. LEGER COPPÉE, M. Am. Soc. C. E.[1]

Died May 8, 1901

Henry St. Leger Coppée, the son of Henry and Julia (DeWitt) Coppée, was born on March 30, 1853, at West Point, N. Y. His father, Henry Coppée, was a graduate of the United States Military Academy in 1845 and had also been a member of the Faculty, afterward becoming President of Lehigh University, at Bethlehem, Pa., which position he filled at the time of his death. After a preparatory education, the boy entered Lehigh University, from which institution he was graduated in 1872, with the degree of Civil Engineer.

After his graduation, Henry St. Leger Coppée entered the employ of the Southern Pacific Railroad Company and, in September, 1872, was engaged on a preliminary survey of that line extending from San Diego, Calif., to Maricopa and Puma Villages, in Arizona. He was afterward promoted to the position of Resident Engineer in charge of construction, with headquarters in San Diego.

During 1874 and 1875, he was Assistant Supervisor with the Pennsylvania Railroad Company, which position he held until 1876, at which time he entered the employ of the Bethlehem Iron Company, at Bethlehem, as Inspector of Materials and Civil Engineer. Mr. Coppée remained in this position until 1878, when he became associated with the Mississippi River Commission as an Assistant Field Engineer in charge of gauging operations near Memphis, Tenn. He remained in this District, under the late William H. H. Benyaurd, Major, Corps of Engineers, U. S. A., M. Am. Soc. C. E., until 1882, engaged on surveys and investigations.

---

[1] Memoir prepared by Charles M. Kerr, Assoc. M. Am. Soc. C. E.

In 1882, Mr. Coppée was transferred to the Vicksburg, Miss., Office of the Mississippi River Commission, and placed in local charge of improvements in the vicinity of that city. He continued in this position until 1892, at which time he was appointed Assistant Engineer of the Third Mississippi River District, which assignment he filled until his death in 1901. During this period he was actively engaged in the general supervision of levee building, bank protection, and other forms of river control and improvement along the Mississippi River and its tributaries in Arkansas, Mississippi, and Louisiana.

Mr. Coppée contributed, at various periods of his career, many technical writings based on his experiences and knowledge of river improvements and flood control. Principal among these was a paper entitled "Bank Revetment on the Lower Mississippi,"[2] for which he was awarded the Thomas Fitch Rowland Prize by the Society in 1896, and a medal at the Paris Exposition in 1900. He received recognition for this paper from all parts of the world from members of the Engineering Profession. Among his other contributions were a paper on "Standard Levee Sections,"[3] and discussions on "Dredges and Dredging"[4] and "The Discharge of the Mississippi River."[5]

Mr. Coppée enjoyed an enviable reputation among members of his profession, and was known as a capable engineer of the highest integrity; the public whom he served regarded him as a trustworthy official; his associates knew him as a constant and loyal friend. The last years of his life were spent in Greenville, Miss., where he served as a member of the Board of Education, and as a Vestryman of St. James Protestant Episcopal Church.

On July 15, 1884, he was married to Mary Bell Marshall, the daughter of Mr. and Mrs. Thomas A. Marshall, of Vicksburg. He is survived by Mrs. Coppée, and two daughters, who are now Mrs. Charles Macdonald Kerr, of New Orleans, La., and Mrs. William Barton Mason, of Orange, Va.

Mr. Coppée was elected a Member of the American Society of Civil Engineers on October 5, 1887.

CHARLES JAMES CRAIGMILE, M. Am. Soc. C. E.[1]

DIED SEPTEMBER 19, 1931

Charles James Craigmile, the youngest son of Alexander and Agnes (Calder) Craigmile, was born on December 27, 1889, at Gifford, Ill. His father and his grandfather came to the United States from Canada at the beginning of the Civil War, to fight with the Federal Armies. Mr. Craigmile was a graduate of the Rantoul, Ill., High School and of the College of Engineering of the University of Illinois, being President of the Class of 1913.

[2] *Transactions*, Am. Soc. C. E., Vol. XXXV (July, 1896), p. 141.

[3] *Loc. cit.*, Vol. XXXIX (June, 1898), p. 191.

[4] *Loc. cit.*, Vol. XL (December, 1898), p. 324.

[5] *Loc. cit.*, Vol. XXXV (July, 1896), p. 319.

[1] Memoir prepared by James H. Lynch, Jr., Assoc. M. Am. Soc. C. E.

Subsequent to his graduation, he was first employed in the Engineering Department of the Pennsylvania Railroad Company. His next position was with the Morgan Engineering Company in connection with a large drainage project in the Mississippi Bayou country; later, he was employed by the Illinois State Highway Department, in which position he superintended the construction of a section of the Great Highway, near Freeport, Ill. He was next engaged with the Engineering Force of the United States Interstate Commerce Commission in the valuation of railroad signal systems; while thus employed he was offered a position in the Engineering Department of the Burlington Railroad Company in a similar capacity, which he accepted.

Upon the entry of the United States into the World War, Mr. Craigmile immediately joined the Officers' Training Camp, at Fort Snelling, Minnesota, where he received his commission as First Lieutenant and was assigned to the 40th Infantry, at Fort Sheridan, Illinois; he was transferred, successively, to the Cavalry, at Camp Stanley, Leon Springs, Tex.; to the Artillery, at Fort Sill, Oklahoma; then to the School of Fire, at Fort Sill; and, later, to the Radio Department of the United States Army, Columbia University, New York, N. Y., where he was engaged at the time of the Armistice. At the conclusion of the war he was commissioned a Captain in the Reserve Officers Training Corps.

On December 23, 1918, Mr. Craigmile joined the Engineering Staff of the North Jersey District Water Supply Commission, being one of the first field engineers employed by the Commission. Work was just beginning on the construction of the Wanaque Reservoir at Wanaque, N. J., which reservoir furnishes the water supply for Newark, N. J., and seven neighboring municipalities. Mr. Craigmile held the position of Senior Assistant Engineer until September 1, 1931, the date of completion of construction on this project.

At the time of the illness which resulted in his death, he was on a vacation tour through the West, prior to joining the Engineering Department of the City of Newark.

His untimely demise has removed an Engineer who was devoted to his profession and whose genial nature had won him a host of friends, both professionally and socially.

Mr. Craigmile was a member of the American Association of Engineers, the American Legion, the Masonic Lodge, of Rantoul, Ill., the Benevolent and Protective Order of Elks, of Paterson, N. J., and the North Jersey Country Club.

He was married on December 12, 1927, to Irene Madeleine O'Crowley, daughter of Richard Joseph O'Crowley, of Newark, N. J., and is survived by his widow, his mother, three sisters, and two brothers.

Mr. Craigmile was elected an Associate Member of the American Society of Civil Engineers on October 14, 1919, and a Member on March 30, 1931.

WILLIAM WARREN CUMMINGS, M. Am. Soc. C. E.[1]

Died April 5, 1930

William Warren Cummings, the son of James Otis and Susan Celina (Bennett) Cummings, was born at Woburn, Mass., on September 13, 1864. He was a direct descendant of David Cummings, of Topsfield, Mass., who came to America in 1650. His mother was a member of the old Bennett family of Boston, Mass.

After receiving his preparatory training at the Woburn High School, Mr. Cummings entered the Rensselaer Polytechnic Institute, at Troy, N. Y., on February 4, 1881, one of the youngest members of his class. He became a member of the Pi Eta Society, later the Rensselaer Society of Engineers. He was graduated on June 18, 1884, with the degree of Civil Engineer, the only degree then given at the Institute.

The esteem in which he was held by his classmates was shown by his election to the office of Life President of the Class, and his excellent scholastic work was evidenced by his appointment, upon graduation, as Assistant in Rational and Technical Mechanics at the Institute.

He resigned this position in 1889, to engage in general engineering practice at Woburn, where he was City Engineer until 1892, when he was appointed to the Engineering Department of the City of Troy, N. Y. In 1893, he was the Engineer of the Mechanicville, N. Y., Water-Works, for which he built a reservoir and a dam. Later in the same year, he was an Instructor at the Colorado School of Mines, Golden, Colo., and, in 1894, he was Assistant Professor of Mathematics and Surveying at the same Institution.

In 1895, Mr. Cummings resumed the practice of his profession, as Engineer in Charge of the design of sewers at Mechanicville, in addition to his private practice. In 1897, he was connected with the Massachusetts Boundary Survey. In 1897-98 he was in charge of the erection of the works of the New England Gas and Coke Company, and, in 1898, he became Assistant Engineer of this Company and also Assistant Engineer of the Massachusetts Pipe Line Gas Company, and, later, the Chief Engineer of these Companies, until 1901.

He was Superintendent of the Isolated Plant Department of the Edison Electric Illuminating Company from 1901 to 1906, and Assistant Manager of the Commercial Department of the Boston Consolidated Gas Company from 1906 to 1910, resigning to resume his private practice, from 1910 to 1915. He then became Manager of the Industrial Fuel Department of the Boston Consolidated Gas Company and Engineer of Utilization for the same Company, from 1915 to 1924.

Mr. Cummings then returned to private practice as a Consulting Engineer, specializing in the industrial use of gas. He constructed coke ovens at

---

[1] Memoir prepared by Prof. C. W. Crockett, Rensselaer Polytechnic Inst., Troy, N. Y.

Everett, Mass.; three tunnels under the Charles and Mystic Rivers; a 42-in. double line of pipes in the congested streets of Boston in winter; in addition to railroad and mill construction, and a large amount of other work.

He was also President of the Industrial Appliance Company of New England from 1924 to January, 1930, at which time his resignation, tendered on account of poor health, was regretfully accepted. He died at Hanover, N. H., on April 5, 1930.

He was a member of the American Society of Mechanical Engineers; American Institute of Electrical Engineers; American Gas Association; New England Gas Association; American Society of Steel Testing; Boston Society of Civil Engineers; and other technical societies.

Mr. Cummings was married on June 28, 1893, to Mary F. McLane, of Troy, N. Y., who died on November 11, 1894, leaving no issue. He was married a second time on June 29, 1898, to Alice Jeeves, of Winchester, Mass., who, with four children (Carl Herrick, William Warren, Jr., Harry Blanchard, and Doris Elizabeth), survives him.

He was a man of great energy and activity, possessing rare judgment and thorough knowledge of his work. He was held in high esteem by all who knew him, not only because of his ability, but also because of his fine personality, high sense of duty, and lovable character.

Mr. Cummings was elected a Member of the American Society of Civil Engineers on June 7, 1899.

SVERRE DAHM, M. Am. Soc. C. E.[1]

DIED FEBRUARY 14, 1932

Sverre Dahm was born in Trondhjem, Norway, on January 2, 1858. His father, Dr. Jacob Christian Dahm, was a graduate of the University of Christiania, and for many years was a Government physician. Later, Dr. Dahm took up private practice in Drammen, Norway. He was greatly beloved as a physician, and continued active until he was more than 80 years of age. In his later life, the Order of St. Olaf was conferred upon him by King Oscar, of Sweden and Norway. Sverre Dahm's grandfather, von Dahm, was a Colonel in the Norwegian Army; the prefix, "von," was dropped when Norway adopted more democratic ideas and abolished all prefixes to proper names. Mr. Dahm's mother, Anneken Louise (Pehrsen) Dahm, was a woman of much originality of character, and was known for her interest in Norwegian antiquities. It was said that, at one time, she possessed the finest private collection of its kind in Norway.

After a preliminary education in the schools of his own country, Mr. Dahm studied Civil Engineering in the Polytechnicum, in Munich, Bavaria, from 1874 to 1878. For the following four years he was an Assistant Engineer on the Government Railways of Norway, engaged on the construction of the Western Railroad.

---

[1] Memoir prepared by Robert Ridgway, Past-President, Am. Soc. C. E., and A. I. Raisman, M. Am. Soc. C. E.

He came to the United States in 1883 and took up the design of bridges and other engineering structures. In the following year, he was a Draftsman for the Union Bridge Company, at Trenton, N. J., and in New York, N. Y. In the same year he was with Pedro Sosa, a contractor engaged in mapping the country about the proposed entrance to the Panama Canal, on the Pacific side, for the French interests then in control of the work. At that time, the control of yellow fever or the malarial diseases which were such scourges in the tropics, was not known, and practically all those who left the United States with Mr. Dahm to engage in this work died within a short time after their arrival on the Isthmus.

In 1885 he returned to the United States and was employed as a Draftsman with the late Theodore Cooper, M. Am. Soc. C. E. After six months' service with Mr. Cooper, he was appointed Assistant Engineer in charge of the Bridge Department of the Long Island Railroad, remaining in that position until 1889. Then, for six months, he was employed as a Draftsman and Computer for the Union Bridge Company, of New York. From 1890 to 1893, he was Chief Draftsman for Albert H. Wolf, Contracting Engineer, Chicago, Ill., and had charge of the steel design for various buildings, including the train-shed for the South Chicago Elevated Railroad.

Subsequently, Mr. Dahm was engaged, from 1894 to 1898, as a Draftsman in charge of structural work for the Jackson Architectural Iron Works, of New York City, and in 1899 and 1900, he was again with Mr. Cooper. All the assignments just described, served as a preparation for the important and responsible work which was to follow and with which he in his future life was to become identified.

On June 20, 1900, he reported as an Assistant Engineer to the Board of Rapid Transit Railroad Commissioners of New York City, then beginning the construction of the first rapid transit subway in that City under the direction of the Chief Engineer, the late William Barclay Parsons, Hon. M. Am. Soc. C. E. Mr. Dahm remained on that work, serving under the various Commissioners and Boards which succeeded each other, until his death.

On June 1, 1905, he was promoted to the position of General Inspector of Designs, succeeding the late St. John Clarke, M. Am. Soc. C. E., when the latter resigned. The position carried with it responsibility for the detail designing of all rapid transit structures, subway and elevated, and the work incidental thereto. He continued in that capacity with successive titles of Principal Assistant Engineer in 1909, Deputy Engineer of Subway Construction in 1919, and Engineer of Design from 1921 until June 16, 1925, when he was appointed Deputy Chief Engineer in Charge of Designs by the Board of Transportation. He was retired on his own application on December 25, 1929, and on the following January 1, 1930, was appointed Consulting Engineer by the Board of Transportation, which position he held until his death.

During the years of Mr. Dahm's service with the rapid transit bodies of New York City, work to the value of about $800 000 000 was designed and built, and for most of this time he was personally in charge of all the designing features. Mr. Dahm left a deep impression on the work and an enviable record for ability, efficiency, and loyalty. His thoroughness of training and the specialized knowledge he possessed of the principles of steel and reinforced concrete design were most valuable assets. His counsel was always sought on intricate matters of design, and his opinion commanded the high respect not only of the engineers of the Board, but of others with whom he came in contact. His sterling character and honesty of purpose impressed every one who knew him, and his kindly spirit and modesty endeared him to all his associates.

Following his death, the Board of Transportation of the City of New York, unanimously adopted the following resolution:

"*Resolved,* That the Board of Transportation of the City of New York does hereby express the sorrow of the members of the Board and of the entire staff of the Board at the loss of a beloved associate in the person of Sverre Dahm, Consulting Engineer of this Board, who died Sunday, February 14, 1932; and whose engineering ability and courteous manner, combined with the highest ideals of public service, attracted the admiration and affection of all of us who knew and worked with him;

"*Resolved,* That the Board of Transportation expresses its appreciation of the exceptional qualifications of Sverre Dahm as General Inspector of Designs, Principal Assistant Engineer, Deputy Engineer of Subway Construction, Engineer of Designs, Deputy Chief Engineer, and Consulting Engineer, and deplores his departure as a great loss to the City of New York."

Many of those who knew this man of slight physique, did not realize that he was just as active physically as he was mentally. One who was near to him writes:

"He was particularly fond of walking and in his earlier years he took long tramps in his native country. During his student years his vacations, all of them, were spent in long tramps in Germany, Italy, and Switzerland, when he averaged thirty or more miles a day for considerable periods of time. In Norway once, on a long tramp through the mountains, he walked over fifty miles in one day and used to tell with enjoyment that when they finally drew up at an inn his guide was so exhausted that he could not eat while he, himself, felt no discomfort.

"Mr. Dahm was also an experienced ski-runner and as long as he lived in Norway he kept up that sport. Running on skis began with him at a very early period of his life and while he was a small boy of five or six years he went to school each day on skis, a distance of six miles from his home in the northern part of Norway where his father was, at that time, government doctor.

"He was, when a young man, so proficient in gymnastics that his instructor urged him to become a professional in that field.

"Later in his life, while in New York, he took up boxing for a short time and for that exercise also he showed aptitude. His boxing instructor said of him, 'he is like lightning on his feet.'

"Mr. Dahm was a man of deep humane feeling and his abhorrence of cruelty extended not only to human beings, but also to dumb animals. For horses, dogs, and cats, he had a great liking. His attitude toward vivisection was characteristic. After a careful study of the vivisectors' published reports he became convinced of the cruelty and futility of vivisection. He was opposed to the practice because of the prolonged and often extreme suffering imposed upon the animals used, and because he considered the practice brutalizing in its effect upon the experimenters themselves. From this conviction he never wavered and until his death he remained affiliated with the Vivisection Investigation League.

"Mr. Dahm's interest in art, especially in his earlier life, was very pronounced and the closest friends of his student years were artists. Several of these young artists—Eilif Peterssen, Harriet Backer, Christian Skredsvig, and Hyerdahl—became, later on, numbered among Norway's most distinguished painters.

"He was keenly interested in literature and, while in Munich, as a young man, he became well acquainted with Henrik Ibsen and his wife who were then staying in Munich. On numerous occasions he was invited to their home and had amusing anecdotes to tell of Ibsen's very outspoken antagonism to 'herd opinion.'

"Mr. Dahm was always fond of reading and in his later years reading and walking were the recreations he enjoyed most."

He was married, in 1898, to Ellen L. Penrose, of Central Village, Conn., who survives him. It is interesting to note that although Mr. Dahm was a comparatively recent arrival in this country, he married Miss Penrose, who could trace her ancestry back to the earliest Colonial days. Roger Williams who settled Rhode Island was one of her ancestors.

Mr. Dahm was elected a Member of the American Society of Civil Engineers on February 7, 1906.

FRANK EUGENE DAVIDSON, M. Am. Soc. C. E.[1]

Died April 14, 1931

Frank Eugene Davidson was born near the Village of Hillsborough, Iowa, on June 7, 1867. He completed the course of Civil Engineering at Iowa State College at Ames, Iowa, in 1890 and immediately thereafter went to Chicago, Ill., where he resided for many years.

On his arrival in Chicago, Mr. Davidson secured employment as a Draftsman with Shailer and Schniglen and several other firms and, in 1895, he went into the general contracting business. In 1898, when Mr. Carter Harrison was elected Mayor of Chicago, he was appointed Superintendent of the Department of Sewers and, later, a member of the Board of Local Improvements. During the two years that he held this position he had direct charge of the redesigning of the intersecting sewer system of Chicago, and, during his administration, the Twelfth and Twenty-Second Street Systems were completed and the Thirty-Ninth Street and Lawrence Avenue Pumping Stations designed. Mr. Davidson recommended certain changes which were adopted by the City Council, that resulted in the saving of hundreds of thousands of dollars to the tax-payers of Chicago.

After two years of service with the City Government, Mr. Davidson resigned and entered the employ of the Illinois Steel Company as a Designer and Structural Engineer. He designed more than $50 000 000 worth of mill buildings for the Company and its allied interests. After four years, he entered the employ of the Western Electric Company as Architect, and as such had direct charge of building operations. In January, 1909, Mr. Davidson formed a co-partnership with the late William R. Patterson, M. Am. Soc. C. E., under the firm name of Patterson and Davidson, entering private practice as an Architect and Engineer, with offices in Chicago, where he remained until his death. In 1911, the co-partnership was changed to an Illinois corporation and Mr. Davidson shortly afterward purchased Mr. Patterson's interest in the firm.

---

[1] Memoir prepared by H. L. Palmer, Director, Illinois Soc. of Architects, Chicago, Ill.

Among the five hundred Chicago plants and buildings designed by Mr. Davidson may be noted the following: the Clearing Plant of the Continental Can Company; the plant of the Pyle National Company; the plants of the W. A. Jones Foundry and Machinery Company, and the Kaestner and Hecht Elevator Company; the Van Buren Street Plant of Hart, Schaffner and Marx; the plants of Metal Specialties Manufacturing Company, and the Standard Cork and Seal Company; and many other important industrial buildings.

Mr. Davidson always devoted a great amount of time to his professional societies and was a member of the American Institute of Architects, the Illinois Society of Architects, serving five times as its President, the National Fire Protection Association, the Chicago Chapter of the American Institute of Architects, the Western Society of Engineers, the Western Efficiency Society, the Architects Club of Chicago and other professional and technical organizations. At the time of his death he was a Director of the Illinois Society of Architects, and Treasurer of the Architects Club of Chicago, which he helped to organize. He was also Editor of the *Bulletin* of the Illinois Society of Architects, which position he had held since the paper was first published.

In politics, Mr. Davidson was a Democrat and was President of the Cook County Democracy, as well as Chairman of the Democratic Political League of Cook County. He devoted much of his time to civic affairs and was a member of the City Club and of several improvement societies. Governor Frank O. Lowden honored Mr. Davidson by appointing him as a member of the State Board of Parks and Buildings Advisers, and his counsel was of great value to the State officials.

He was an enthusiastic sportsman and a crack rifle shot, as well as an expert at trap shooting. He was also interested in billiards and played a good game of chess, but devoted his spare hours during the summer to cultivating a garden, as he was passionately fond of flowers and had one of the finest gardens on the east side of Lake Michigan.

Building contractors, in general, referred to Mr. Davidson as one from whom they always "got a square deal." His guiding policy as a professional and business man was the "Golden Rule."

At times, Mr. Davidson appeared to be rather abrupt with representatives of material houses, and when the writer remonstrated with him, he smiled and said,

"I never want to see salesmen unless I am in a position to do them some good and in the mean time I am doing them a real service by not taking up their time when they could be finding an architect in the market for their products."

His seemingly gruff exterior housed a heart of gold, and he was in reality very kindly, one who was ever ready to help the younger men who chose the Architectural Profession. His loyalty to his friends and business associates could not be exceeded, and those who knew him loved him. He will be missed by his friends and the organizations to which he belonged.

Mr. Davidson was elected a Member of the American Society of Civil Engineers on November 4, 1908.

JOSEPH PHINEAS DAVIS, M. Am. Soc. C. E.[1]

Died March 31, 1917

Joseph Phineas Davis was born in Northboro, Mass., on April 15, 1837, the son of William Eager and Almira L. (Sherman) Davis. All the lines of Mr. Davis' ancestry lead back to men and women who came early to New England, many of whom were active and efficient in the establishment of American institutions. On the paternal side, he was descended in the seventh generation, from Captain Dolor Davis and Margery Willard, who came to New England in 1634. On the maternal side, he was descended from Captain John Sherman, who came to America in 1634 and settled in Watertown, Mass. The home in Northboro was established in 1773 by Mr. Davis' great-grandfather, Deacon Isaac Davis, who went there from Rutland, Mass., and became a successful tanner.

Mr. Davis was graduated from Rensselaer Polytechnic Institute in Troy, N. Y., in 1856, at the age of 19. Immediately afterward, he was engaged as a Rodman at $1.25 per day on the Brooklyn, N. Y., Water-Works, later being promoted to the position of Transitman at $2.00 per day. The party had charge of the building of the foundations and the construction of Mt. Prospect Reservoir and Engine House. Mr. Davis directed the building of Engine House No. 2, in the Ridgewood Section of Brooklyn and his salary was increased to $60.00 per month.

In the summer of 1860, on hearing that the Peruvian Government wished the services of three American engineers, Mr. Davis made a proposition through the Peruvian Minister for a contract for five years at $4 000 per year, one-half payable in gold. While awaiting a decision, the Civil War broke out. Mr. Davis was drilling with a Brooklyn regiment when he saw the troops pass through New York, N. Y., on their way South in April, 1861. He then went to the Peruvian Minister to withdraw his proposition. To his surprise, the Minister drew out a bag containing $2 000 in gold and informed him that he was bound by his contract.

---

[1] Memoir compiled by Charles W. Sherman, M. Am. Soc. C. E., mainly from a memoir prepared by the late Frederic P. Stearns, Past-President, Am. Soc. C. E., and the late Edward W. Howe, M. Am. Soc. C. E., and published in the *Journal*, Boston Soc. of Civ. Engrs., Vol. 4, p. 37; also, from "The Story of Electricity" (1919), by T. C. Martin and S. L. Coles; and from "A Brief Sketch of the Telephonic Career of Joseph P. Davis," furnished in manuscript by the American Telephone & Telegraph Co. The compiler has made liberal transcripts from these sources, without using quotation marks.

In July, 1861, he went to Peru by way of Panama, and, during the next four years, made surveys, plans, and reports for water supplies, bridges, railroads, sewerage systems, and other public works. Probably, the most important piece of work he did while in Peru was to survey the great guano beds of Lobos and the coast north of Lima. This work lasted from October, 1862, to May, 1863.

Although the contract with the Peruvian Government was for five years, Mr. Davis returned to the United States in July, 1865, receiving a leave of absence, as a revolution was threatening. The revolution was successful, and the Engineer Corps was abolished. Mr. Davis was then appointed Assistant Engineer to lay a 48-in. main from the Ridgewood Reservoir to Brooklyn. In June, 1866, he was made Chief Engineer of Prospect Park, but in May, 1867, he was offered the position of Principal Assistant Engineer on the St. Louis (Mo.), Water-Works, which was about to be constructed. He accepted this offer, went to St. Louis, and, under the direction of the late T. J. Whitman, M. Am. Soc. C. E., at once began plans for putting the work under contract.

Early in 1870, he was appointed Chief Engineer of the Lowell, Mass., Water Commissioners, who had recently been chosen to build a new system of water supply for that city. Mr. Davis designed and placed under contract the new supply.

In November, 1871, he was appointed Chief Engineer of the Cochituate Water Board, to investigate and report on an additional water supply for Boston, Mass. After making a thorough investigation of all sources available, he recommended a supply from the Sudbury River. Works for this purpose were carried out under his direction and completed in 1880, within his estimate of cost, which was approximately $5 000 000.

In 1872, the office of City Engineer of Boston became vacant, and as there were differences of opinion in the City Government as to the engineer to be elected to this office, the matter was referred to a commission of prominent engineers, which reported, recommending the selection of Mr. Davis, and his election followed. The Commission stated in its report, after referring to the qualifications of other candidates:

> "Mr. Davis, in addition to a thorough special education as an engineer, has had a more varied and valuable professional experience than either of the other gentlemen. Especially in that branch of his profession which relates to the supply and distribution of water, and water work generally, does he appear to be eminently qualified. He has filled important positions upon several works of great magnitude, and of others he has had the full responsibility as chief engineer. The testimony of engineers of the highest professional reputation is fully given to his capacity and attainments, and to the excellence of the work he has done. As the final result of their examination and inquiry, the board are unanimous in the opinion that he best embraces the qualifications most important for the discharge of the responsible duties of city engineer."

It is to be noted that at the time of his election he was thirty-five years of age. He was City Engineer only from 1872 to 1880, when he resigned to accept a more important position, but during that comparatively brief time he completed an additional water supply for Boston, and, after visiting Europe and studying the sewerage systems of the larger cities, planned and began the construction of the comprehensive works for improved sewerage, now called the Main Drainage Works of Boston. This, however, was by no means the extent of his achievements in this position. He at once established the engineering of the city in all departments under his charge on a thoroughly sound basis.

At the time of Mr. Davis' election as City Engineer, the office had been organized only three years. His principal assistants were a group of young men who were extremely fortunate in having the benefit of the excellent engineering training which Mr. Davis could give, and in being subject to the remarkable influence which he had upon those with whom he was associated. He was thoroughly appreciative of the endeavors of his subordinates to do good work, and there are many of them who recall with pleasure and gratitude the time spent in service under his direction. Not only were these subordinates so greatly benefited by association with him, but they became so imbued with his views and methods that long after he resigned as City Engineer, his influence was a controlling factor in the conduct of the engineering work of the city.

In March, 1880, Mr. Davis joined the American Bell Telephone Company as Consulting Engineer; in 1891, he became its Chief Engineer, and continued in this position with the Company and its successor, the American Telephone and Telegraph Company, until 1905, when failing eyesight compelled him to relinquish the more active work; he remained, however, as Consulting Engineer of the Company until the end of 1908.

When he began his telephonic career, less than three years after the construction of the first telephone line, the streets and housetops of the larger cities were fast becoming unsightly from the mass of overhead wires. These, with the lofty poles and cumbersome roof structures which supported them, proved highly vulnerable to sleet storms, and were the frequent cause of serious disruption of the telephone service.

Mr. Davis was charged with the responsibility of devising a suitable method of placing the wires underground. Innumerable schemes had been suggested, practically all of which were valueless, but as there was no strictly underground telephone system in any part of the world, the Company had no guide except its own experiments.

His first important task was to design and direct the installation of the first "drawing-in" underground conduit system ever constructed. This work was carried out in Boston in the latter part of 1882, and served as a model for subsequent installations. Wrought-iron boiler tubes, encased in concrete, were used for the duct material, and manholes were placed at intervals for the purpose of drawing in and splicing the cables. Great care was taken to exclude water from the finished structure. So correct were the methods used in this first "drawing-in" system, and so workmanlike was its construction, that the conduits were reported as still in use nearly thirty years later.

During the years that followed, Mr. Davis placed the underground conduit construction of the Bell System on a sound engineering basis. He formulated the methods that should be used, not only in the actual building of the conduit systems but also in determining in which streets the conduits should be placed, and the most economical number of ducts to install, taking into account both present and future requirements. He and his assistants visited all the larger cities throughout the United States and gathered data to be used in the preparation of comprehensive conduit plans for those cities.

From these conduit plans of Mr. Davis developed the work on "Market and Development Studies and Fundamental Plans," which for many years has been one of the important engineering undertakings of the Bell System. These studies include a critical analysis of the existing market for telephone service in a community and pertinent facts as to the present sale of the various classes of service, upon which are based forecasts of the probable size, distribution, and character of the future market and its telephone requirements. These forecasts of future telephone requirements permit the preparation of a comprehensive plan to serve as a basis for the layout of the plant at a date fifteen or twenty years in the future.

During his long service with the Bell System, Mr. Davis was active as a Director and Officer of many of the local operating companies. He was one of the incorporators of the Metropolitan Telephone and Telegraph Company of New York City in 1880, and of its successor, the New York Telephone Company, in 1896. He was First Vice-President of these Companies during almost the entire period from 1880 to 1902, and a Director and member of the Executive Committee for even a longer period. He was appointed Consulting Engineer of the Metropolitan Telephone and Telegraph Company in July, 1887, and took an active part in the design and construction of the first underground conduit systems installed in New York City.

Mr. Davis was for several years President and a Director of the Hudson River Telephone Company and of the Westchester Telephone Company; he was also a Director of the following Companies: the Union Telephone Company; the Northern New York Telephone Company; the New York and New Jersey Telephone Company; the New York and Pennsylvania Telephone and Telegraph Company; the Empire City Subway Company; the Chesapeake and Potomac Telephone Company; the Southern Bell Telephone and Telegraph Company; the Bell Telephone Company of Buffalo; the Central District and Printing Telegraph Company; and the Chicago Telephone Company.

He acted as Consulting Engineer of boards and commissions on many important undertakings, including the Croton Aqueduct Commission from 1884 to 1886, the Massachusetts State Board of Health from 1886 to 1904, the Metropolitan Water Board and its successor, the Metropolitan Water and Sewerage Board, from 1895 to 1909; and the Metropolitan Sewerage Commission in 1898.

Mr. Davis was active in the re-organization of the Boston Society of Civil Engineers in 1874; he became its President in 1880, and an Honorary

Member in 1908. He was also a member of the American Society of Mechanical Engineers, the American Institute of Electrical Engineers, and the Society of Telegraphic Engineers and Electricians (of England).

Mr. Davis was elected a Member of the American Society of Civil Engineers on January 29, 1868, and served as Director in 1878 and again from 1881 to 1883, and as Vice-President in 1884.

JOHN STANLEY DAWSON, M. Am. Soc. C. E.[1]

Died August 6, 1931

John Stanley Dawson, the son of Thomas and Hattie (Stanley) Dawson, was a native Kentuckian, having been born at Bloomfield, in Nelson County, on June 23, 1888.

Mr. Dawson received his early education at Bardstown, Ky., and then entered upon the study of Civil Engineering at the University of Kentucky, in Lexington, from which he was graduated on June 2, 1910, with the degree of Bachelor of Civil Engineering. During his college course he was rated as a splendid student and acquired a thorough knowledge of the fundamentals of his chosen profession.

After graduation he received his first position as a Rodman with the Louisville and Nashville Railroad Company, and continued in its service, with but little interruption, until August, 1916. During this period of employment he was promoted from Rodman to Assistant Resident Engineer and Resident Engineer, and received a broad, practical experience in railway location, relocation, staking out excavations, and bridge design and construction. As Resident Engineer he was in charge of heavy mountainous construction, including bridges, tunnels, and yard work, and discharged all the duties assigned to him with efficiency and dispatch.

In August, 1916, Mr. Dawson was appointed a Division Engineer with the Kentucky State Highway Department and served in that capacity until August, 1917. During this period he rendered meritorious service to his native State in the pioneer days of road and bridge building in Kentucky.

In August, 1917, he answered the call of his country and enlisted in the United States Army for service in the World War. He was assigned to the Second Officers Training Camp at Fort Benjamin Harrison, in Indiana. At the completion of this training he was commissioned a Second Lieutenant in the Field Artillery, which rank he held until the end of the war, serving as an Instructor in other training camps.

After Mr. Dawson's discharge from the Army he returned to the Kentucky State Highway Department and was reinstated in his former position of Division Engineer. In December, 1920, he was promoted to the position of Engineer of Maintenance of the Department and was placed in charge of the maintenance of all State highways in Kentucky, which position he held until his health broke down in March, 1924, compelling him to resign and seek relief in another climate.

---

[1] Memoir prepared by Joe S. Boggs, Esq., Frankfort, Ky.

During the four years that Mr. Dawson was Engineer of Maintenance the activities of this branch of the Department were greatly enlarged due to the rapid expansion of the road funds and the public demand for better maintained State highways. By careful selection of efficient employees, by close attention to details, and by the introduction of modern methods of highway maintenance and up-to-date machinery, Mr. Dawson built up in Kentucky a maintenance organization equal to that in any State.

After his resignation in the early part of 1924, he went to Tucson, Ariz., seeking the restoration of his health. He lived there until June, 1929, at which time he returned to Kentucky where he resided, until his death at the U. S. Veterans Hospital, at Lexington, on August 6, 1931. During all these years of illness, although unable to engage in any kind of employment, he displayed a remarkable fortitude and a cheerful patience with an incurable affliction, seldom seen in any one under like circumstances.

Mr. Dawson was married on November 10, 1915, to Bessie McDaniel, of Franklin, Tenn., a most worthy helpmate and companion during the years of his active professional life and his constant attendant after his health gave way. To her and his one child, a daughter, he was devoted, and longed to recover his health so that he could better safeguard their future welfare and happiness.

In the passing of John Stanley Dawson, Kentucky has lost a valuable citizen, his profession an outstanding member, his family a devoted husband and father, and his associates a staunch and loyal friend, whose place cannot be filled.

Mr. Dawson was elected a Member of the American Society of Civil Engineers on June 1, 1920.

FLOYD GOSSETT DESSERY, M. Am. Soc. C. E.[1]

Died May 12, 1927

Floyd Gossett Dessery, the son of Alfred B. and Mary M. (Gossett) Dessery, was born in Leavenworth, Kans., on February 10, 1879. When the family moved to California he attended Grammar School and High School in Los Angeles. In June, 1898, he left High School and enlisted in Battery H, Third United States Heavy Artillery, and saw two years of active service in the Philippine Islands during the Spanish-American War and the Insular Insurrection.

On his return from Army service, Mr. Dessery began his engineering career as a member of field survey parties, working from the offices of the City Engineer of Los Angeles and the County Surveyor of Los Angeles County. Later, he was employed by the Los Angeles and Salt Lake Railway Company, and made a transmission line location survey in Kern County, California, for the Pacific Light and Power Company. During the construction of the Pacific Electric Railway Company's interurban system in Southern California, from 1902 to 1905, he was Transitman and Locating Engineer for that Company. In 1906 Mr. Dessery served the City of Los Angeles as Field Engineer and Hydrographer and, later, made hydrographic surveys for the Los Angeles Dock and Terminal Company's development of the inner harbor at Long Beach, Calif.

---

[1] Memoir prepared by Ralph J. Reed, M. Am. Soc. C. E.

From the fall of 1906 until the summer of 1908, he was associated with F. S. Noble, Consulting Engineer, on various water supply and highway projects; and at the conclusion of this engagement he opened his own office, continuing in private practice until his death. For several years he shared offices with the late James Dix Schuyler, M. Am. Soc. C. E., and was associated with Mr. Schuyler on a number of projects. From 1910 to 1912, he was in partnership with the late Mr. George W. West, under the firm name of Dessery and West.

Prior to the consolidation of Wilmington, Calif., and Los Angeles, Mr. Dessery was Harbor Engineer for the City of Wilmington in charge of the design and construction of harbor slips. As a result of his familiarity with conditions in the harbor district, he was employed as an Engineering Consultant in a number of lawsuits involving tide-land interests at San Pedro, Calif. For about twelve years he was Engineer for the Consolidated Lumber Company, designing and constructing the channel, turning basin, and wharves at its large Wilmington Plant.

Mr. Dessery was City Engineer of Covina, Calif., from 1908 to 1914, served for several years as City Engineer of Glendora, and of Upland, and from 1915 to 1918 was Consulting Engineer for the City of Coalinga, Calif., on the design and installation of its water supply system. In 1920 he was retained by the Governor of the Northern District of Baja California (Mexico) as Consultant on various water supply and sewerage systems, in particular the municipal water system for the City of Mexicali. About this time he was also engaged for several years in the improvement, for Mr. William R. Hearst, of the great San Simeon Ranch in San Luis Obispo County, California.

When the development of the extensive Palos Verdes Estates was undertaken in 1921 and 1922, Mr. Dessery was a member of the Engineering Commission directing this work and, about the same time, he served as Consulting Engineer to Los Angeles County Water-Works District No. 4. Throughout his practice, Mr. Dessery was frequently employed as a Consultant by land companies, water companies, and municipalities because of his wide experience in problems of hydraulics and water supply.

Ill health forced Mr. Dessery to give up active practice nearly a year before his death, which occurred at his home in Los Angeles, on May 12, 1927.

He was a member of the Sons of the American Revolution, The Society of American Military Engineers, the American Water Works Association, and the Jonathan Club of Los Angeles. As a Charter Member of the Los Angeles Section of the Society, he was an enthusiastic participant in its development and devoted much time to its interests, serving with great fidelity as its Secretary from 1919 to 1924.

He was married on September 6, 1905, to Julia M. Morrison who, with two sons, Floyd Gordon and Gerald Morrison, survives him.

Mr. Dessery was elected an Associate Member of the American Society of Civil Engineers on February 28, 1911, and a Member on July 11, 1921.

HARRY ESPENSHIP DETWILER, M. Am. Soc. C. E.[1]

DIED FEBRUARY 19, 1931

Harry Espenship Detwiler was born at Oaks, Pa., on April 3, 1874. During his boyhood he attended the public schools of his native town, but owing to the early death of his parents, he was thrown upon his own resources when he was very young. Being of a resourceful and studious nature, he worked around the Pencoyd Plant of the American Bridge Company, and pursued his studies through correspondence courses in Structural Drafting.

His first regular work with the Pencoyd Iron Works was in 1896 and 1897 as Inspector in the Fabricating Shop. He later was appointed Shop Foreman.

In 1900, Mr. Detwiler became connected with the Structural Iron and Steel Company, of Baltimore, Md., as a Structural Draftman, and, from 1901 to 1906, he served the Lauer and Harper Company, of Baltimore, as Chief Draftsman and, later, as Designing Engineer on structural steel work for bridges, piers, etc.

He was employed by the City of Baltimore as Assistant Engineer in the City Park Department in 1906 and 1907. He then accepted a position as Assistant Engineer of Bridges and Buildings with the Seaboard Air Line Railway, with headquarters in Portsmouth, Va. In 1909, he associated himself with the York Bridge Company, of York, Pa., as Designer in the Engineering Department.

In 1914 Mr. Detwiler moved to Scranton, Pa., where he associated himself with Mr. Boyd A. Müsser, in organizing the Anthracite Bridge Company, serving as Secretary-Treasurer, and also as Chief Engineer, until his death.

With his great capacity for detail, and studious application, Mr. Detwiler developed into a most valuable Designing and Consulting Engineer, particularly as applied to structural steel work. His training and experience were recognized, and his services appreciated, by the leaders in the anthracite coal industry, and he was continually being consulted on construction problems peculiar to this industry. He was also helpful to architects, county, city, and consulting engineers in their engineering problems. In all these contacts he was very zealous in maintaining a high code of ethics for the Engineering Profession.

He was not only a competent and efficient Engineer, but he was much interested in problems that were helpful in making communities more beautiful. He was recognized as an authority on wild flowers, and he took a great interest in legislation for their protection.

---

[1] Memoir prepared by Boyd A. Musser, Pres. and Mgr., Anthracite Bridge Co., Scranton, Pa.

Until his final illness which began on December 6, 1930, Mr. Detwiler was active in civic, engineering, and industrial organizations of the community in which he lived. He was especially active in Lions International, having served as President of his Local Club, and also as Governor for the State of Pennsylvania. He took great interest in the American Institute of Steel Construction, and served on committees of importance in that organization. He leaves a widow and one daughter, who reside in Philadelphia, Pa.

Mr. Detwiler was elected a Member of the American Society of Civil Engineers on October 14, 1929.

FREDERIC CLARK DUNLAP, M. Am. Soc. C. E.[1]

Died January 25, 1928

Frederic Clark Dunlap, the son of George and Jennie (Chattin) Dunlap, was born on February 8, 1869, at Mullica Hill, N. J. He received a common school education in Camden, N. J., and was a Special Student in Engineering at the Lauderbach Academy and Polytechnic School in Philadelphia, Pa., in 1885 and 1886.

In 1887, Mr. Dunlap entered the office of Howard Murphy, Civil Engineer, of Philadelphia, and in 1888 and 1889, was in charge of outside work, surveys, etc., for Mr. Murphy, including the construction of water supply works at Merchantville, N. J., and Roanoke, Radford, Richlands, and Luray Inn, Va., testing pumping machinery for Lynchburg, Va., and water power installations at New River, Va., and Fayetteville, N. C.

In private practice as Engineer and as Contractor, from 1890 to 1893, he built portions of water-works at Red Bank, N. J., and Hyndman, Pa. From 1894 to 1896, he was Assistant Superintendent of the Union Hydraulic Works, Philadelphia, engaged in the manufacture of supplies for water-works. In 1896 and 1897, he was Assistant Engineer for the contractor on the new water supply for Camden, N. J., Superintendent of Construction of water-works at Egg Harbor, N. J., and made surveys, plans, and estimates for water-power projects on the Delaware River at Trenton and Lambertville, N. J., and for a power project on the Susquehanna River.

In 1898, Mr. Dunlap was Superintendent of a building operation in Overbrook Heights, Philadelphia. For six months in 1899, he was an Assistant Engineer with the Bell Telephone Company, in Philadelphia, but resigned to accept an appointment with the City of Philadelphia then beginning an extensive water purification project. Ten years' experience in the construction of smaller water supply plants in many sections of the United States served as an invaluable training for the work which he now began and to which he gave the best of his life.

---

[1] Memoir prepared by Vernon R. Dunlap, M. Am. Soc. C. E.

In 1900 and 1901, he was Assistant Engineer on designs for the improvement of the Philadelphia Water Supply, under the late John W. Hill, M. Am. Soc. C. E., and from 1902 to 1905, he was in charge of the construction of the Torresdale Filter Plant, the largest filtration plant in the world at that time. In 1906, he was employed for a short time on designs for the subway in North Broad Street, Philadelphia, and then went to New York, N. Y., as an Assistant Engineer in the Department of Water, Gas, and Electricity in that city.

On May 1, 1907, Mr. Dunlap returned to Philadelphia as Chief of the Bureau of Filtration and remained in charge of the Water Bureau, with which the Bureau of Filtration was consolidated, until September 15, 1912. During this period the Queen Lane Filtration Plant was completed, extensive improvements were made in pumping and distribution mains, and filtered water for the first time was furnished to every section of the City of Philadelphia.

He resigned as Chief of the Water Bureau and spent the winter of 1912–13 in the West endeavoring to recover from a chronic rheumatic condition that he had endured for a number of years. He returned to Philadelphia and, in 1914 and 1915, was employed by the National Dredging Company in the development of its gravel and sand deposits. In 1916, he returned to the employ of the City in the Division of Sewage Disposal, and, later, as Assistant Chief Engineer, Department of City Transit.

With the outbreak of the World War Mr. Dunlap applied for a commission in the Corps of Civil Engineers, United States Navy, but was offered an appointment in the Bureau of Yards and Docks as a Civilian Engineer by the Navy Department. In the interim, he had accepted the position of Chief of the Bureau of Highways, Philadelphia and was requested to remain at his new post by the Mayor.

He served as Chief of the Bureau of Highways from June 1, 1917, until June 1, 1923, when he was transferred again to his former position as Chief of the Bureau of Water. The situation with regard to the water supply of the City of Philadelphia had reached a point at which it appeared that steps must be taken to secure an increased supply at an early date. A plan had been advocated and had received support looking for further development of the Schuylkill water-shed and that of the Lower Delaware. Mr. Dunlap's studies led him to believe that a better and more economical plan for an increased supply would be to adopt substantially the one advocated many years before to bring water from the Delaware River above Trenton, N. J., to Philadelphia. This plan developed and announced in detail aroused violent opposition from political sources, with the consequence that with a change in City Administration shortly thereafter, Mr. Dunlap's resignation was requested and accepted on February 1, 1924, although as yet no engineering investigation had been made into the question at issue.

The challenge presented to Mr. Dunlap was promptly met. Although he had never before engaged in public speaking, he began, on his own time and at his own expense, to interest civic bodies and societies in the questions involved. In plain language and with facts and figures presented in a manner that non-technical audiences could appreciate, he won the support of the newspapers as well as the public and prevented the adoption by the City of a plan which, in his experience and judgment, did not appear to be an economical and safe method of securing an increased water supply. He followed up this action by personally representing the City's interests before the Commission engaged in preparing a Tri-State agreement for the division of the water rights in the Upper Delaware River water-shed, avoiding the surrender of rights to which the City appeared to be entitled. His outstanding position in the water supply controversy was recognized by his appointment as Chief of the Bureau of Water for the third time in January, 1928, thus vindicating his action of four years previous.

Mr. Dunlap's restoration to the Water Bureau was followed almost immediately by the beginning of an illness which developed into pneumonia and resulted in his death on January 25, 1928. His passing came at his prime when his usefulness to his City which he had served for a score of years would have been most valuable. He had endeared himself to his subordinates and associates, many of whom he had taken from minor positions and developed as executives. His life exemplified that of many loyal municipal and Government employees who have and are giving their best to the service of their fellow men in a manner that frequently receives scant notice and recognition.

In 1891, Mr. Dunlap was married to Alice Palmer, the daughter of J. Albert and Mary Rea Palmer, of Camden. He is survived by his widow and by his two sons, Vernon R. Dunlap, M. Am. Soc. C. E., and George A. Dunlap.

He was a member of the Union League of Philadelphia, the Engineers Club of Philadelphia, the American Water Works Association, and the Municipal Engineers of New York.

Mr. Dunlap was elected a Member of the American Society of Civil Engineers on June 1, 1904.

JAMES HARVEY EDWARDS, M. Am. Soc. C. E.[1]

Died August 14, 1930

James Harvey Edwards was born on June 19, 1864, in Oxford, N Y. His early education was obtained in the district school of Oxford and the Oxford Academy, where he prepared for Cornell University. His father owned and operated an iron foundry in Oxford, and the son spent his spare time from school and vacations in the foundry. He thus obtained a practical experience which was to prove of value in his later career as an engineer.

In the fall of 1884, he entered Cornell University, at Ithaca, N. Y., and was graduated in June, 1888, with the degree of Civil Engineer. During his college career, he was President of his Class in his Sophomore year, Captain of one of the cadet military companies, and Chief Engineer of his

---

[1] Memoir prepared by a Committee consisting of H. G. Balcom, Charles Stratton Davis, and J. E. Wadsworth, Members, Am. Soc. C. E., and R. Fleming, Esq., New York, N. Y.

Class in his Senior year. He was a member of the Delta Upsilon Fraternity and was elected a member of the honorary societies, Sigma Xi and Tau Beta Phi.

Immediately after his graduation, Mr. Edwards entered the employ of the Union Stock Yards in Chicago, Ill., where he remained until the fall of 1888, when he accepted a position with the Berlin Iron Bridge Company, of East Berlin, Conn., as a Structural Steel Draftsman. For the subject of his graduating thesis he had chosen a bridge built by the Berlin Iron Bridge Company, in Oxford. It was on the merits of this thesis that he obtained his position with the Company. He was promoted to be Chief Draftsman in 1890, made Assistant to the Vice-President in 1891, and Chief Engineer in 1897.

At the time that Mr. Edwards entered the employ of the Berlin Iron Bridge Company, steel was beginning to replace wood in the construction of factory and mill buildings and the Company seeing the possibilities in this type of construction, made it a specialty. The success of the Company was due largely to the ability of Mr. Edwards as a designer of this type of buildings.

In 1900, the Berlin Iron Bridge Company was merged into the American Bridge Company, and Mr. Edwards was made Structural Engineer, in charge of building work. In 1901, he was made Assistant Chief Engineer, and, in 1927, Chief Engineer, which position he held at the time of his death in New York City after an illness of only three days.

When the United States entered the World War, Mr. Edwards was assigned by the American Bridge Company as its representative on all war contracts with the United States Government.

Soon after the close of the war, Mr. Edwards took up the study of fusion welding. Although all his former training and experience had been along the line of riveted connections, he soon became convinced that there was a future in fusion welding. As he had been a pioneer in the design of steel mill buildings, so he now became a pioneer in the design of welded structures. At Mr. Edwards' suggestion, the American Bridge Company established a welding shop at Trenton, N. J. His combined engineering and business ability enabled the Company to secure contracts for a number of the principal welded structures of the United States.

He became an active member of the American Welding Society, of which he was elected a Vice-President and Chairman of the Committee on Structural Steel Welding. In the latter capacity, he was instrumental in having the Committee arrange for a series of tests which are now (1931) in progress. In 1929, the Society awarded to him the Miller Medal for conspicuous work in fusion welding.

In 1916, Mr. Edwards was placed in charge of the design of all steel structures for the plants of the United States Steel Corporation. In that capacity he had charge of the design of the new mills at Homestead, Pa., Gary, Ind., South Chicago, Ill., and Lorain, Ohio. He was also appointed a member of the Committee on the Design of I-Beam Sections, which Committee developed the new Carnegie Beam Sections of the Corporation.

Mr. Edwards was deeply interested in educational matters. He was elected Alumni Trustee of Cornell University for three successive 5-year terms (1906–1921). During his term of service he was instrumental in combining the Colleges of Civil, Mechanical, and Electrical Engineering into one College of Engineering. As Chairman of the Buildings and Grounds Committee, he had a large part in the building of the new Armory Hall and the new dormitories for men.

Mr. Edwards was a member of the American Railway Engineering Association, the American Society for Testing Materials, the American Welding Society, the American Iron and Steel Institute, the Society for the Promotion of Engineering Education, the Cornell Society of Engineers, the Engineers Club, and also of several social organizations. He was a member of the Merchants Association Commission, organized to prepare a new Building Code for New York City.

In 1892, Mr. Edwards was married to Mabel T. Davis, of Binghamton, N. Y., who, with four sons, Robert D., J. Leland (Assoc. M. Am. Soc. C. E.), John C., and David A., and one daughter, Elizabeth (Mrs. Richard W. Schabacher), survives him.

At the meeting of the Board of Direction of the Society held at St. Louis, Mo., on September 29, 1930, the following resolution in memory of Mr. Edwards was unanimously adopted:

"*Whereas:* In the providence of Almighty God: James Harvey Edwards, Member, has been removed from our midst, and

"*Whereas:* He has served with distinction as a Director of the Society during the years 1913 to 1915; as a member of its Committees on Steel Columns and Struts; on Stresses in Structural Steel; and as the Society's Representative on Building Code Committee of the U. S. Department of Commerce; Sectional Committee on Steel Shapes of the American Standards Committee; and on various other committees: and

"*Whereas:* He gave liberally of his time toward the advancement of engineering practice and methods of his energetic labors, tempered by good judgment and keen analysis of conditions, always keeping in mind the best interests of the Society, the Engineering Profession, and the Public:

"*Therefore Be It Resolved:* That the members of the Board of Direction of the American Society of Civil Engineers spread upon the records their profound sense of loss to the Society, the Engineering Profession, and the Public:

"That they express their deep sympathy for the family in their great bereavement: and,

"That a copy of this preamble and resolution be sent to Mrs. James Harvey Edwards, for the family."

The passing of Mr. Edwards leaves a large gap in the ranks of the Engineering Profession. He will be missed and mourned by a host of friends outside as well as within the Profession.

"He was a man, take him for all in all,
I shall not look upon his like again."

Mr. Edwards was elected a Junior of the American Society of Civil Engineers on May 31, 1892, an Associate Member on May 2, 1894, and a Member on May 4, 1898. He had served as a Director of the Society from 1913 to 1915.

GEORGE EZRA ELLIS, M. Am. Soc. C. E.[1]

Died December 17, 1931

George Ezra Ellis was born at Fairhaven, Mass., on January 13, 1870, the only child of Hiram B. and Sarah D. Ellis. His early education was secured in the public schools of Fairhaven, and he was graduated from Rensselaer Polytechnic Institute, at Troy, N. Y., in June, 1892, with the degree of Civil Engineer.

Upon graduation Mr. Ellis was engaged by the New York Central and Hudson River Railroad Company (now the New York Central Railroad Company) as Signal Inspector on various divisions until June, 1898. Among his duties in this connection was charge of the construction and operation of interlocking and block signals. From June, 1898, to June, 1900, he was Assistant Superintendent of Signals of the same road, during which time he designed and constructed an interlocking plant amounting to more than 200 levers. He was also Superintendent of the Hudson River Bridge Company, in charge of the maintenance and operation of two New York Central and Hudson River Railroad bridges (each about $\frac{1}{3}$ mile in length) over the Hudson River, at Albany, N. Y.

His subsequent career was as follows: From June 1900, to 1902, Signal Engineer, Standard Signal Company, in charge of estimating, designing, and constructing interlocking plants installed on various railroads, including 300 levers of mechanical and 180 levers of pneumatic interlocking on the New York Central and Hudson River Railroad, at Buffalo, N. Y. From 1902 to 1904 he was Western Agent for the Pneumatic Signal Company; and, during 1904, he was also Assistant Chief Engineer of the General Railway Signal Company.

In 1904, Mr. Ellis again entered active railroad work as Signal Engineer of the Chicago, Rock Island and Pacific Railroad Company, with headquarters at Chicago, Ill., and continued in this capacity until 1908. During the next two years, he was connected with the Federal Signal Company and the Hayes Track Appliance Company, re-entering the railroad field as Signal Engineer of the Kansas City Terminal Railway Company in 1910, which position he held until 1915. During this period he was active in the work incident to the rehabilitation of the Kansas City Terminal properties, involving elaborate construction work on the signal system of the new Terminal.

From 1915 to 1920, Mr. Ellis was with the Bureau of Safety of the Interstate Commerce Commission as Senior Signal Engineer, and during the last two years of that period he also served as Executive Secretary of the Automatic Train Control Committee of the United States Railroad Administration.

Upon the organization of the Committee on Automatic Train Control of the American Railway Association, in November, 1920, Mr. Ellis, as the individual best fitted by experience and qualification to handle this work, was appointed its Secretary, which position he held until his death. In April, 1930, when the Joint Committee on Grade Crossing Protection of the American Railway Association was organized, he was also chosen as its Secretary.

---

[1] Memoir prepared by E. A. Hadley, M. Am. Soc. C. E.

Practically the whole of Mr. Ellis' engineering career was in the field of railway signaling and automatic train control. His outstanding fitness for the position of Secretary of the Committee on Automatic Train Control had its foundation in his relationship as Executive Secretary to the Automatic Train Control Committee of the United States Railroad Administration. The investigations by this body were the basis of a knowledge that was increased with subsequent development of the art, so that, at the time of his death, Mr. Ellis probably had at his finger tips the details and characteristics of automatic train-control systems, to a greater extent than any one else in the United States. This is admirably indicated by the fact that he was selected to write the treatise on this subject for the World Engineering Congress held in Tokyo, Japan, in 1929, and a similar paper for presentation in the latest edition of the Encyclopedia Brittanica. He also wrote many articles for various technical magazines, and, upon request, delivered numerous addresses before railway and engineering societies upon the subject in which he was most interested.

Mr. Ellis always manifested an active interest in his Alma Mater, and was greatly interested in its Alumni activities. His realization of the value of an education, and his desire to help those not financially able to secure it, is indicated by the number of young men whom he assisted in procuring an education at Rensselaer Polytechnic Institute.

In his personal as well as in professional circles, Mr. Ellis made many warm friendships which, when once created, continued whole-heartedly. His friendship and loyalty were prized very highly among those who knew him best.

He was never married, and, at the time of his death, had no immediate relatives.

Mr. Ellis was elected a Junior of the American Society of Civil Engineers on March 2, 1897, an Associate Member on March 7, 1900, and a Member on December 4, 1901.

CHARLES CLEMENT ELWELL, M. Am. Soc. C. E.[1]

Died May 21, 1931

Charles Clement Elwell, the son of Benjamin T. and Martha (Wilson) Elwell, was born at Belfast, Me., on July 16, 1855. Before he was seven years old, the family moved to Aroostook County in the extreme northeastern corner of the United States. During the next five years his school attendance was confined to short terms of eight to twelve weeks in summer at crude schools taught by equally crude local schoolmasters or mistresses. Although his schooling, which had begun propitiously at Belfast, was interrupted by the move, the rough and independent life of a frontier farmer and woodsman may have given him as much benefit in sound health, a strong body, and ability to meet and overcome difficulties courageously, as he might otherwise have had from continuance in the city schools. However, from the age of twelve to sixteen years, he attended the Academy at Patten, Me., and came under the instruction of a master who inspired him with a desire for a better education than might be expected to come naturally to one in his situation. As the summer term of the country school near his home happened to be at just the time when Patten Academy had its vacation, he took advantage of the opportunity thus presented and these four years saw almost continuous attendance at school.

---

[1] Memoir prepared by Herbert C. Keith and Joseph P. Wadhams, Members, Am. Soc. C. E.

After graduation from the Academy, young Elwell became uneasy and "desired to strike out for himself and see the world." In April, 1872, his father consented, but "with the stipulation that the father should go along and start the son in the new venture." His study of history and geography had prepared him to enjoy a great thrill as they passed through Boston, Mass., and New York City, on their way "out West" to Elmira, N. Y. The travel also gave him a desire to become a railroad man, and he tried to get a position with the Erie Railroad Company. Although his youth prevented its accomplishment at that time, the desire never left him as long as he lived. The "hard times" of the following winter, and consequent unemployment, turned them homeward again, and they found a lighted lamp in the window as a beacon, although his mother had not received the letter advising of their intention to return (this light had been burning every night for them for several weeks). Although not profitable financially the trip had broadened Mr. Elwell's outlook and increased his desire for a better education, and he returned to Patten Academy for advance work. Another year also was spent there as a student, with the added position as Assistant to the Principal, and was followed by two years more of teaching in other Maine schools.

In 1876, Mr. Elwell entered the University of Maine, at Orono, in the Sophomore Class, and was graduated in 1878 with the degree of Civil Engineer. Fifty years after his graduation, the University gave him the additional degree of Doctor of Engineering.

In February, 1879, he entered the United States Lighthouse Engineer Corps, Sixth District, and continued therein until 1882, being stationed at various points on the South Carolina, Georgia, and Florida Coasts.

In January, 1882, Mr. Elwell entered the employ of the New York and New England Railroad Company as Assistant Engineer of Maintenance of Way, transferring a few months later (when the Maintenance-of-Way Department was abolished) to a similar position in the merged Engineering Department. Here, he had charge of building the docks and freight yards for the Hudson River Terminal at Fishkill-on-Hudson (later Beacon), N. Y.

In August, 1884, he was called by his old Chief in the Maintenance-of-Way Department of the New York and New England Railroad Company, Major F. L. Hills (who also had been his military instructor at the University of Maine and his superior in the Lighthouse Engineer Department), to the position of Assistant Chief Engineer of the Wilmington and Northern Railroad, with an office at Wilmington, Del.

In 1891, Mr. Elwell became Engineer of Maintenance of Way for the Philadelphia Division of the Baltimore and Ohio Railroad Company; and a few months later was transferred to the Pittsburgh Division with headquarters at Pittsburgh, Pa., where he replaced a large amount of timber and pile trestles by earth fills.

Two years later, he was called to the New York, New Haven and Hartford Railroad Company, beginning in April, 1893, as Roadmaster for the New York Division during its rebuilding, which consisted of four-tracking, making great changes of line and grade, and installing first-class construction and equipment throughout. On this work, under his direction, many alleged "impossibilities" were accomplished in the way of shifting track for long distances transversely and vertically without interference with traffic even to the extent of slowing down the expresses. These accomplishments were observed by the management with such appreciation that Mr. Elwell was appointed a Delegate to the International Railway Congress, at London, England, in 1895, and given a nine weeks' trip through Europe at the expense of the Railroad Company.

Soon after his return from the Railway Congress and the trip through Europe, in November, 1895, the New York and New England Railroad having been acquired by the New York, New Haven and Hartford Railroad Company and re-organized as the New England Railroad, Mr. Elwell was made Superintendent of its Norwich and Worcester Division, together with the steamboat line from Ally's Point, Conn., to New York City; this was his first position in charge of operating traffic other than "work trains." When the New England Railroad was absorbed by the New York, New Haven and Hartford Railroad Company in 1898, he continued to serve as Superintendent of these lines for the consolidated road. In 1901, he was transferred to the combined Air Line and Northampton Divisions, and, in 1904, to the Shore Line Division (which at that time combined what formerly had been three divisions).

In 1908, Mr. Elwell was made Chief Engineer of the Connecticut Company and several smaller separate lines, comprising all the trolley roads of the New York, New Haven and Hartford Railroad Company in Connecticut and New York State. During his administration there was considerable strengthening of the bridges on this 1 000-mile network of railways, and otherwise improving them.

When the Connecticut Public Commission was organized in 1911 to take over the authority and duties of the former Railroad Commission, together with similar and enlarged authority over all public utility companies of the State, Mr. Elwell was appointed its Chief Engineer, and served in that capacity until 1915, when he was appointed a Commissioner to fill the vacancy caused by the retirement of one of the original members. By two re-appointments he retained this position until his death, on May 21, 1931.

Mr. Elwell was a man of broad vision and a large capacity to create according to that vision; and he accomplished successfully, with economy, many tasks which observers had confidently declared to be impossible. He had a keen sense of justice, coupled with a kind and sympathetic nature, that enabled him in many times of stress and ill-feeling to bring order and harmony out of turmoil and hatred. Not only was he an able broad-minded engineer of large and varied experience, but he was also a man of such genial personality and human sympathy that he endeared himself to all with whom he came in contact whether a superior officer, a subordinate, or one with whom the association was only social or even casual; he inspired confidence in his judgment and ability and also in his fair-mindedness.

Among the publications prepared by Mr. Elwell are papers on: "Lighthouse Construction on the Southern Coast[2]"; "The Railroad Grade Crossing Problem"; "Development of Bus Transportation"; "Street Railway and Motor Bus Regulation"; "How Public Utilities Should Treat the Public"; and "Derailments."[3]

Mr. Elwell was married on March 25, 1885, to Nancy I. Bolton, who, with their sons, Francis Bolton Elwell and Charles Clement Elwell, Jr., survives him.

Although not very active in politics, and valuing a candidate according to his merit rather than according to his party, he was a Republican; in religion, he was a Congregationalist. In his club affiliations, he was a member of the Graduates Club of New Haven, Conn., and of the Hartford Club and the University Club of Hartford. He was an Honorary Member and Past-President of the Connecticut Society of Civil Engineers, and had been a member and President of the Association of New England Railroad Superintendents.

Mr. Elwell was elected a Member of the American Society of Civil Engineers on July 1, 1891, and served as a Director from 1919 to 1921, inclusive. As Director, he was active in organizing, and took great interest in, the Local Sections of the Society.

FRANK COLLINS EMERSON, M. Am. Soc. C. E.[1]

DIED FEBRUARY 18, 1931

Frank Collins Emerson, the son of Byron D. and Anne (Pendell) Emerson, was born on May 26, 1882, at Saginaw, Mich. He attended the public schools of his native town, graduating from the Saginaw High School in 1900. In the fall of that year he entered the University of Michigan, Ann

[3] *Loc cit.,* 1914, p. 80.

[1] Memoir prepared by H. D. Comstock, J. A. Elliott, and Z. E. Sevison, Members, Am. Soc. C. E.

Arbor, Mich., from which he was graduated in 1904, with a degree of Bachelor of Science in Civil Engineering.

Mr. Emerson's first professional employment was at his home town of Saginaw where he was Assistant City Engineer from June to September, 1904, when he felt the call of the West and moved to Wyoming which was thereafter his home. He first located in what is now Sublette County, near the Post Office of Cora. For the next few months he was engaged in private practice in that locality, largely on small irrigation projects, and it was during that time that he gave evidence of a characteristic which was to stamp his subsequent career, namely, that of making himself generally useful to his community.

From May to October, 1905, Mr. Emerson was employed by the La Prele Ditch and Reservoir Company, near Douglas, Wyo., in charge of canal location, and from October, 1905, to March, 1906, he served the Saratoga and Encampment Valley Railroad Company as Assistant Engineer in charge of the location of 45 miles of railroad through a mountainous country between Walcott and Encampment, Wyo. From March to June, 1906, he was employed by the State Engineer of Wyoming to locate two large canals on the Shoshone Indian Reservation. Fifteen years later the Wyoming Canal was built by the United States Bureau of Reclamation on substantially the location made by Mr. Emerson. From June, 1906, to April, 1907, he was Chief Engineer of the La Prele Ditch and Reservoir Company, in charge of canal construction.

In April, 1907, he was appointed Chief Engineer of the Wyoming Land and Irrigation Company in full charge of the location, design, construction, and operation of that Company's irrigation projects on Paint Rock and Shell Creeks in the Big Horn Basin in Wyoming. In 1909, the Shell Canal providing water for 11 300 acres was completed, and to provide against a possible shortage, the Adelaide Lake Reservoir was built in 1912 and 1913. He continued in charge of these projects until December, 1914. On account of financial difficulties the projects were taken over by the Court and from December, 1913, to March, 1914, Mr. Emerson acted in the capacity of Special Master Commissioner of the Fifth Judicial District of Wyoming, and, later, from March to December, 1914, he was Chief Engineer of the Wyoming Irrigation Company, successor to the Wyoming Land and Irrigation Company.

In December, 1914, he was appointed Superintendent of the Big Horn Canal Association at Worland, Wyo., and supervised the reconstruction of the Big Horn Canal, replacing temporary structures with permanent ones of concrete and steel. Later, he was also appointed Superintendent of the Lower Hanover Canal Association with similar duties. He continued in these positions until June, 1919. During much of this period Mr. Emerson was also Engineer for the Wyoming Sugar Company and the Worland, Worland-Bench, and Colter Drainage Districts. These positions involved the supervision of a large amount of construction work near Worland. At the same time, he was engaged in general engineering practice, mainly but not exclusively in irrigation and drainage.

In June, 1919, Mr. Emerson was appointed State Engineer of Wyoming and took office on July 1, 1919. Thereafter, until his untimely death, he played the leading part in the development of the water resources of Wyoming and, indeed, in all matters pertaining to irrigation and drainage. His work took him through all parts of the State, and he formed a wide acquaintance, especially in those communities where irrigation is extensively practiced.

In March, 1923, as the outcome of a controversy over his re-appointment as State Engineer, Governor William B. Ross summarily removed him from office. He contested his removal in the Courts, and the State Supreme Court held that the attempted removal was illegal, and that Mr. Emerson was in fact still State Engineer.

Irrigation and drainage bonds had lost favor with the investing public, and Mr. Emerson was largely influential in securing the passage by the Legislature of 1923 of the Act permitting the investment of the permanent funds of Wyoming in bonds of irrigation and drainage districts within the State. Under the terms of this Act a large amount of irrigation and drainage development was carried out, which otherwise could have been financed only on unfavorable terms, if at all.

In 1921, Mr. Emerson was appointed Wyoming Commissioner on the Joint Colorado River Commission, of which Herbert Hoover, Hon. M. Am. Soc. C. E., representing the Federal Government, was Chairman. After protracted negotiations covering the seemingly irreconcilable interests of the various States, the now famous Colorado River Compact was finally signed by all the Commissioners on November 24, 1922. This compact was then ratified by the Wyoming Legislature in January, 1923, the ratification being contingent on similar ratification by the Legislatures of the other six States in the Colorado River Basin, and by Congress. Two years later, in February, 1925, it became advisable to provide for ratification without waiting for Arizona, but a bill for that purpose met with indifference on the part of the Legislature and the State Administration, and it was only through the persistent and untiring efforts of Mr. Emerson that it was enacted, making possible the present development at Boulder Canyon on the Colorado River. A subsequent attempt by the 1929 Legislature to repeal this ratification was successfully resisted by him as Governor.

His abundant energy and concern for the development and welfare of Wyoming led to widespread demand that he serve the State as Governor and, after mature deliberation, in the spring of 1926 he "threw his hat in the ring." He won the Republican nomination by a good majority, and after a spirited contest in which unusual factors were involved, he was elected Governor by a plurality of about 1 200 votes over the Democratic candidate for re-election, Governor Nellie T. Ross, the widow of former Governor William B. Ross. With his record of an able active administration, Mr. Emerson was renominated for Governor on the Republican ticket in 1930, and after a hotly contested campaign he was re-elected by a plurality of about 1 000 over Mr. Leslie A. Miller, the Democratic candidate.

His work as Governor was a continuation and extension of his work as State Engineer. He considered himself not only the political head, but also the active manager of the Wyoming Administration and, as such, he took an active part in all departments of the State Government. He was intensely interested in all enterprises which seemed to effect the development, prosperity, and welfare of his State. This policy led him to be an ardent champion of States' rights as against Federal control in such matters as river regulation and the administration of the public lands. He worked constantly to safeguard for use in Wyoming the waters that arise in that State. He strongly opposed the Federal policy of limiting oil development on the public lands. Notwithstanding this attitude, no Governor enjoyed to a greater extent the respect and confidence of the Federal officials with whom he came in contact. He endeavored to promote the legitimate industries of the whole State and to that end he was a forceful and convincing speaker and was in great demand as such.

Governor Emerson's health was impaired by hard work during the campaign of 1930, and by equally intensive application to the duties of his office both before and during the session of the Legislature. He contracted a cold about February 10, but continued at the Executive Office until February 13, when pneumonia set in. His condition immediately became serious, and the end came on February 18, 1931.

Governor Emerson was a member and regular attendant of the First Baptist Church, of Cheyenne. He was a member of the Lions Club and of the Benevolent and Protective Order of Elks, a Thirty-second Degree Mason, and a Knight Templar. In 1918, he was one of the Founders and the first President of the Wyoming Engineering Society.

He was always active in community matters and took a leading part in many enterprises during his residence in Worland. Neither his character nor his integrity was ever questioned. Countless friends mourn his loss. He was essentially a builder, and belonged to that long line of pioneers who through unfaltering determination have developed, and are still developing, the resources of this Nation. His character has been well described in the following editorial from the *Wyoming State Tribune:*

> "The golden sunlight of a benign February day caresses Wyoming, but its brilliancy cannot dispel a pall of gloom that oppresses the State, nor its warmth cannot alleviate the benumbing chill of grief in hearts that mourn a beloved chief executive stricken by the hand of death in the full power of his high ability.
>
> "It is difficult for the people of the State he served so ably and with such self-immolating devotion to comprehend that virile, dynamic Frank C. Emerson is dead—that the brilliant mind that reasoned his shrewd and effective leadership is extinguished, that his body of seemingly inexhaustible energy is inert in death—we cannot think of him as insensate, immobile, he was so the embodiment of intellectual and physical vigor.
>
> "He died in time of peace, this devoted champion of the people's rights, but no embattled warrior that ever went down fighting in martial strife more truly laid down his life in patriotic service to the public weal than did Wyoming's heroic executive. Literally he sacrificed his life in his determination to give to his office the fullest measure of his abilities. He held service above self, he exhausted himself in service—he died for his ideal of service in the fullest need and so dying placed his State forever in memory under obligation to him.

"'Carry on' was the guiding rule of his devotion to his office; 'carry on' regardless of difficulties, regardless of obstacles, regardless of effects to self—'carry on' for Wyoming. He required the personnel of his administrative organization to adhere to that ideal, he adhered to it himself unswervingly—he 'carried on' to the very threshold of death and there gallantly faced the cost of his sacrifice, willing to pay it rather than to falter in devotion to official duty.

"What a glowing, an ennobling heritage that spirit has given his sons, his fellow-citizens, his successor in the governorship. Ever when we think of him we will have it in mind, visualizing his features as radiant with the light of a holy zeal to lead with the example and inspiration of service given by self as well as commanded of others. There could be no finer legacy.

"'Carry on'! That command, now a message from the dead, reverberates amid the gloom of grief that enshrouds a State to-day. The chosen leader is gone, but his precept is immortal—sorrowing, we 'carry on'."

On January 17, 1910, he was married to Zennia Jean Reynders who survives him, with three sons, Frank, David, and Eugene.

Mr. Emerson was elected a Member of the American Society of Civil Engineers on May 13, 1918. He was also a Member of the Irrigation Division of the Society, and, in 1926, he served on its Executive Committee.

LLOYD TILGHMAN EMORY, M. Am. Soc. C. E.[1]

Died January 5, 1931

Lloyd Tilghman Emory, the son of Edward B. and Henrietta (Tilghman) Emory, was born at "Poplar Grove", near Centerville, Md., on August 8, 1882. He was descended from a family which has been prominent on the Eastern Shore of Maryland since Colonial times.

It was necessary for Mr. Emory to start work when he was sixteen years old, and his first position was with the Washington Gas Light Company. It had always been his ambition to become an Engineer and in June, 1899, he was engaged as Instrument Bearer, Rodman, and Recorder on triangulation and shore-line work with the United States Coast and Geodetic Survey.

His next work was in the West as Assistant Draftsman on locating parties, running preliminary lines and locations in Oklahoma, for the Choctaw, Oklahoma, and Gulf Railroad Company. From November, 1902, to March, 1903, he was Topographer with locating parties of the Little Rock and Southern Railroad Company and, from March to September, 1903, he served as Topographer on location and Instrumentman on the construction of the Midland Valley Railroad Lines south of Fort Smith, Ark.

Throughout these years, Mr. Emory studied and saved and in October, 1903, he was able to enter the Senior Class at the Jacob Tome Institute, Port Deposit, Md. He was graduated in June, 1904, receiving the Lehigh University Scholarship, He entered the University of Pennsylvania in the fall of 1904, from which he was graduated in 1908, with the degree of Bachelor of Science in Engineering. In 1911, on submission of a post-graduate thesis, he received the degree of Civil Engineer from the University of Pennsylvania.

---

[1] Memoir prepared from information supplied by Mrs. Emory and on file at the Headquarters of the Society.

His first position after leaving college was that of Inspector and Chief of Party on the Hackensack Approach to the Pennsylvania Railroad Tunnels. In May, 1909, he was put in charge of construction of the McIntyre, Ga., Plant of the Kaolin Mining Company and, on its completion, he was made General Superintendent in charge of operation.

From 1911 to December, 1915, Mr. Emory was a member of the firm of Emory and Eisenbrey, Civil, Chemical, and Industrial Engineers, with offices in Philadelphia, Pa. His work consisted largely of making reports on various engineering projects, and plans and specifications for industrial plants and topographic surveys. It was during this period that he had an interesting trip to Sardis, in Asia Minor, with the Butler Archæological Expedition.

In December, 1915, Mr. Emory was engaged to go to South America on a short inspection trip which proved longer than he had anticipated. During 1916, he was Engineer in charge of field work in Dutch Guiana, South America, for the Republic Mining and Manufacturing Company, a subsidiary of the Aluminum Company of America. His work consisted of exploration of practically unknown territory in a tropical country, topographic mapping, test pitting, diamond drilling of bauxite deposits, and the preparation of estimates of ore bodies. In December, 1916, he was made Manager of the Demerara Bauxite Company, Ltd., of British Guiana, with headquarters in Georgetown, the capital of the Colony. He held this position until he joined the United States Army in 1918.

While in British Guiana, Mr. Emory was selected by the Governor of the Colony as one of three arbitrators to settle a dispute between the Government and the Case Coast Defense Company, a contracting firm then at work on the $2 500 000 sea wall. After a hearing, lasting eleven days, a compromise was effected.

After receiving his discharge from the Army at the close of the World War, Mr. Emory re-opened his office in Philadelphia as a Consulting Engineer, making reports and investigations for various clients, mostly in South America and Europe.

He was a man of great reserve, but those who knew him loved him, and men working with him admired and respected him for his depth of understanding and the sincerity with which he took hold of the job on hand. Whatever he achieved in life, he gained by his own determination to succeed. Engineering was his great hobby as well as his life work, although he had a wealth of information on many subjects and a great interest in outdoor recreations.

He had been engaged in work in Europe for some months previous to his death which came rather suddenly in Barcelona, Spain, on January 5, 1931, following a severe attack of influenza.

He was married on June 2, 1924, to Alice Martenis, of Wilmington, Del., who, with one child, Lloyd Tilghman Emory, Jr., survives him.

Mr. Emory was elected a Junior of the American Society of Civil Engineers on October 5, 1909, an Associate Member on April 2, 1912, and a Member on January 20, 1920.

HOWARD RICHARDS FARNSWORTH, M. Am. Soc. C. E.[1]

DIED FEBRUARY 6, 1931

Howard Richards Farnsworth was born at Atchison, Kans., on December 21, 1886, the son of D. E. and Emma (Richards) Farnsworth.

Mr. Farnsworth attended the public schools of his native town and following graduation from Atchison City High School, he entered the University of Kansas, Lawrence, Kans. He completed the prescribed four-year course in the Civil Engineering School, attending as a resident student during the years 1904-1909, inclusive, with the exception of the fall and winter of 1907 and the spring of 1908, but it was not until 1921 that he submitted his thesis and was graduated from the University of Kansas, receiving the degree of Bachelor of Science in Civil Engineering on December 19 of that year. While a student at the University he was very prominent in musical activities, and was a member of Alpha Tau Omega, a social fraternity.

From June to August, 1906, Mr. Farnsworth was employed by the Kansas City-Southern and Louisiana Central Railroad Companies as Chainman in Louisiana. From August, 1907, to September, 1908, he was with a field party of the United States Examiner of Surveys in South Dakota and Nebraska, first as a Chainman and, later, as Principal Assistant.

From February, 1909, to April, 1924, Mr. Farnsworth was with the Cadastral Engineering Service of the United States General Land Office. During this period he was employed in the following capacities: From February, 1909, to April, 1917, as United States Surveyor, during which time the months from May to December of each year were spent as Chief of Party in the field in the execution of cadastral retracement resurveys in Nebraska, including stellar observations, investigations, and reports, and from January to April each year in the office of District No. 3 at Neligh, Nebr., computing proportions, balancing closures, checking astronomical data, and preparing records of field work with details and final plats; from May, 1917, to June, 1921, Reviewing Engineer in the Administrative Office of the Commissioner of the General Land Office, Washington, D. C., reviewing plans, specifications, and returns of cadastral engineering projects; from July, 1921, to April, 1924, as Cadastral Engineer in the Commissioner's Office and, during this period from February, 1922, to April, 1924, a member of the Manual Board in the preparation of the "Manual of Instructions for the Survey of the Public Lands of the United States."

---

[1] Memoir prepared by John M. Alden, Esq., Muskogee, Okla.

In April, 1924, Mr. Farnsworth decided to change his sphere of activity and enter the oil industry. In May, 1924, he was transferred to the Petroleum Division of the United States Bureau of Mines as an Assistant Petroleum Engineer and stationed at Taft, Calif., in connection with the supervision of oil and gas operations on the public domain and Naval petroleum reserves. In July, 1925, this activity was transferred from the Bureau of Mines to the United States Geological Survey. Mr. Farnsworth remained with the United States Geological Survey until his death in 1931.

In his new line of endeavor Mr. Farnsworth progressed rapidly. He interested himself in the geological and paleontological investigations in oil-field development in California and became well versed in these matters. His petroleum engineering activities also included sub-surface studies of the Elk Hills (Naval petroleum reserve), Kettleman Hills, and Maricopa Flats Oil Fields, on which he prepared extensive reports.

In January, 1931, he was transferred from Taft, Calif., to Tulsa, Okla., to continue his petroleum engineering work under the United States Geological Survey, and was made a District Engineer.

Mr. Farnsworth contributed materially to the various engineering activities in which he was engaged. During his association with the United States General Land Office, he published a paper[2] entitled, "A Review of Important Developments in the Science of Cadastral Resurveys as Executed by the United States Government, with Ethical Discussion Thereof."

Another paper[3] entitled "Elk Hills, California," of which Mr. Farnsworth was co-author with Messrs. W. P. Woodring and P. F. Roundy, is now (1932)' in the course of publication. This paper deals with geological conditions and the accumulation and production of oil and gas in the Elk Hills Naval Petroleum Reserve, in California. Mr. Farnsworth was also the author of a "Report on the Sedimentation of the Sunset Oilfield and the Extension of the Thirty-Five Anticline, in California."[4]

He was a member of Trowell Lodge No. 71, A. F. and A. M., of Neligh, Nebr., Mt. Moriah Lodge, of Perfection, Nebr., Semper Fidelis Chapter, Knight Rose Croix, St. Andrew's Preceptory, Nebraska Consistory, and Tangier Temple, A. A. O. N. M. S., all of Omaha, Nebr.

The engaging personality of the man made lasting friends of his associates. His advancement in the several phase of the Engineering Profession was due to excellent ability and training. He not only took part in the practical phases of his calling, but also contributed to the literature of engineering and geology. Persistent and capable, likable and friendly, strong and efficient, Mr. Farnsworth left an impression that will not soon be forgotten by all who knew him. He is survived by his widow, Elizabeth Chestnut Farnsworth.

Mr. Farnsworth was elected an Associate Member of the American Society of Civil Engineers on April 17, 1917, and a Member on January 14, 1924.

FRANK FOSTER, M. Am. Soc. C. E.[1]

DIED APRIL 21, 1931

Frank Foster was born in Manchester, England, on May 1, 1865, the fourth son of T. Barham Foster, M. Inst. C. E. He was educated at Haileybury College, England, and in January, 1884, was articled for the usual period of three years to E. B. Thornhill, Assistant to Francis Stephenson, Chief Engineer of the London and North Western Railway.

The first half of this time was spent on the design of bridges and structures, principally for the Soho to Handsworth and Perry Bar Junction Railway, in the Birmingham District, and the other half upon the construction of that branch railway, which, although of no great length, included a tunnel through the most varying subsoils, a viaduct, large bridges, and heavy excavation and embankment.

On the termination of the three years, Mr. Foster joined his father's firm which then became Foster, Son, and Bardsley, and during the next four years was busily engaged with the construction of water service and drainage works at Motteram and Hollingworth and several other townships in the Midlands, in England, and attending as witness in Parliamentary and law cases referring to concessions for railways, water-works, floods, etc.

Wishing to increase his experience farther afield, Mr. Foster obtained the appointment as Junior Construction Engineer on the Buenos Aires Great Southern Railway, arriving in the Argentine Republic on November 16, 1890.

His first work was on the construction of a line from Las Flores to Tandil, and, on its completion, he took part in running a survey for a new line (to be constructed many years later), from Olavarria through Pringles and the Sierra Ventana Hills to Bahia Blanca, and on another line from General Alvear to Carhue.

As all construction work was being stopped owing to the severe financial straits of the country, known as the Baring crisis, Mr. Foster transferred to the maintenance side of railway engineering, becoming Assistant Engineer on the Buenos Aires Western Railway, in 1892, with which Company he remained during his working life. He was first stationed on the La Plata Lines, with headquarters at Tolosa, but in six months he was promoted to the Home Division radiating from the main terminal station in the City of Buenos Aires. He remained there for six years, during the last two of which he also acted as Engineer in Charge of the entire System. During the latter part of this period, the financial crisis began to pass off, and many minor but important works came under his care, apart from those of ordinary routine.

In September, 1898, Mr. Foster was definitely appointed Chief Engineer, and ten years later, in addition to this post, he was named Assistant Manager, passing to the General Managership in October, 1915. As General Manager, he remained until his retirement in 1928.

---

[1] Memoir prepared by A. W. Dannatyne, Esq., of Buenos Aires, Argentine Republic, and London, England.

During his tenure of office as Engineer-in-Chief, more than two-thirds of the 1 926 miles of line which now form the Buenos Aires Western Railway, were laid, and the present terminal station in Buenos Aires was built. This latter work involved the lowering and quadruplication of the main line to eliminate all grade crossings for a distance of 2¼ miles from the terminus, at a cost of $1 250 000. At the same time, new locomotive and carriage and wagon shops were built at a cost of $2 500 000, and sub-terminals with extensive marshaling yards and locomotive depots were laid down where necessary throughout the System.

In 1910, the preliminary works were begun for the construction of a tunnel 3¼ miles long, under the city, to convey freight to the dockside for shipment, and, conjointly, the studies were made for the electrification of 23 miles of the main line, for suburban passenger traffic, electric traction being used likewise in the freight tunnel. A new underground passenger station was built in the city in conjunction with the Anglo-Argentine Tramway Company, for the quick transference of the passengers between train and tram. The electrification entailed heavy works and rebuilding in many of the suburban stations, the raising of the platforms in all stations to make them level with the floors of the cars, and the quadrupling of the tracks for 16 miles. The tunnel was completed on February 14, 1916, and was worked temporarily by steam locomotives, the World War delaying the inauguration of the electric service until April 30, 1923.

Mr. Foster devoted his energies during the war, to aid in every way the cause of the Allies and in spite of the difficulties due to the impossibility of obtaining materials, particularly coal, and the absence at the front of so many of the Staff, no interruption occurred in the transport of the countless head of cattle and tons of grain to the seaboard for shipment to the seat of war. For his patriotic services the distinction of the Order of the British Empire was conferred upon him.

Mr. Foster was elected a Member of the Institution of Civil Engineers (England), in December, 1904. He took a prominent part in the organization of the Association of British Engineers in the Argentine Republic in 1921, and was elected an Honorary Member for his services. He was also a member of the Institute of Transport, Argentine Center, and of the British Chamber of Commerce, taking an active interest in the British Engineering Standards Association.

He devoted his life to the interests of the Railway Company with which he was so long connected, and, at the same time, was always willing to give freely of his knowledge and experience to any who came to him for counsel or advice, not only as a skilled engineer, but also as a man of the world. He was greatly esteemed by all his associates and friends to whom his sudden death, so soon after his retirement, came as a severe blow.

In 1895, Mr. Foster was married to Caroline A. M. Adams, daughter of William Adams, M. Inst. C. E. (England), at that time Chief Engineer of the Buenos Aires Western Railway. He is survived by Mrs. Foster, two daughters, and a son.

Mr. Foster was elected a Member of the American Society of Civil Engineers, on June 30, 1911.

HERMANN FOUGNER, M. Am. Soc. C. E.[1]

DIED MARCH 9, 1932

Hermann Fougner was born at Hustad, Norway, on March 23, 1877, the son of Colonel Johan Herman Severin Fougner and Frederikke Margaretha (Jenssen) Fougner. He came from a prominent family of land owners, which for many generations has contributed to the Government services of Norway in high positions in the Army and Navy, as well as the Civil Service, and the Government itself. His uncle, Francis Hagerup, was twice Prime Minister of Norway under King Oscar II, and his father had received from King Christian IX, of Denmark, the rank of Commander of the First Class of the Order of Dannebroge. King Oscar II had himself honored Colonel Fougner on two occasions: First as Knight of St. Olaf, First Class; and, second, as Knight of the Order of the Sword, First Class.

As a boy, Hermann Fougner was permitted to accompany his father during school vacations on long surveying journeys through the mountains of Central Norway, where Colonel Fougner had charge of the Government surveys before taking command of the cavalry forces in Northern Norway. It was with this background that Mr. Fougner inherited his interest for civil engineering and love of outdoor life, which he also maintained in his adopted country.

After graduating from High School, Mr. Fougner studied engineering for four years at the Technical College, of Trondhjem, Norway, and was graduated, after taking the supplementary course of practical surveying, with the degree of Civil Engineer in 1896.

In the spring of 1897 he arrived in United States, and began his engineering career as Junior Engineer and Draftsman with the Pencoyd Iron Works, of Philadelphia, Pa. During the following three years, he made steady progress and gained a thorough experience in the design and erection of all kinds of structural work, as well as steel freight-car design, with the Koken Iron Works, of St. Louis, Mo., and the American Steel Foundry Company, of Granite City, Ill.

During the summer of 1900 Mr. Fougner visited Europe and, on his return to New York, became connected with Milliken Brothers, at that time, a leading concern of steel constructors in many parts of the world. The following year this Corporation placed him in charge of a large contract with the Russian Government for harbor works at Port Arthur, in Manchuria. This work comprised a naval basin, large cranes, storehouses, and magazines, for the Imperial Russian Navy. This construction was completed just before the Russo-Japanese War began. When the Japanese bombarded Port Arthur they destroyed almost all this development.

After more than a year in Port Arthur, Mr. Fougner proceeded to South Africa, as Chief Engineer for the Johannesburg Office of Milliken Brothers, traveling there *via* Shanghai, China, Singapore, Straits Settlements, and Colombo, Ceylon. For two and one-half years he had charge of the design and construction of some of the largest steel buildings in Johannesburg, including several leading banks, and office buildings for the gold and diamond mining companies. This marked the introduction of structural steel for buildings in South Africa.

---

[1] Memoir prepared by Charles T. Rundlet, Esq., Larchmont, N. Y., and Nicolay K. Fougner, M. Am. Soc. C. E.

On his return to New York in 1905, Mr. Fougner was engaged by the Trussed Concrete Steel Company (now the Truscon Steel Company) of Youngstown, Ohio, and assumed charge of its New York Office as Agent and Engineer. For more than twelve years he managed this office, and at the same time maintained a private consulting practice. Reinforced concrete was then still in its infancy, and few of the older generation of engineers and architects had any knowledge of the design or use of this material. Mr. Fougner saw the great possibilities of reinforced concrete and studied its development intensively. As a result he was recognized as one of the leading concrete engineers in the United States, and developed a large and profitable business for the products manufactured by the Corporation that he represented. During the years, 1909 to 1911, Mr. Fougner lectured on reinforced concrete at Pratt Institute, in Brooklyn, N. Y.

Many of the best known reinforced concrete structures of this pioneer period were designed in Mr. Fougner's office. As examples, the following may be mentioned: The reinforced concrete viaduct in Richmond, Va., which was built on a curve, and was the longest and most outstanding concrete viaduct in the world at that time; the Marlborough-Blenheim Hotel, in Atlantic City, N. J., with the largest concrete dome built to that date; the Traymore Hotel in the same city; and hundreds of other large buildings, bridges, reservoirs, and other structures, including the engineering design of the buildings at the United States Military Academy, at West Point, N. Y.

Early in 1918, during the World War, Mr. Fougner engaged in the construction of concrete ships, in partnership with his younger brother who, the previous year, had invented and successfully constructed the first sea-going concrete ship at Moss, Norway.

The Fougner Concrete Shipbuilding Company received a contract from the United States Shipping Board for several sea-going vessels, but was first required to construct a shipyard entirely at its own expense. Therefore, only the first of the Government ships was completed, when the war ended a few months later, and all Government contracts were cancelled. The enormous over-production of tonnage automatically stopped all further shipbuilding of steel, as well as of concrete.

After the war Mr. Fougner returned to his consulting practice, and of his work at this time a notable example is the Mergenthaler Linotype Company's large plant in Brooklyn, N. Y., and many other industrial buildings. For some years, from 1922 to 1927, he also took an active interest in contracting, as Vice-President of Thompson and Binger and, later, with the Industrial Engineering Company, both of New York City. He then formed a partnership, Fougner and Gautier, with Raoul C. Gautier, M. Am. Soc. C. E., a

French engineer and architect, and was engaged especially in the design of industrial buildings, swimming pools, breakwaters, and harbor improvements.

During his last years Mr. Fougner made a study of the engineering aspect of handling freight motor trucks in connection with terminals and warehouses, and was granted patents on improved methods of floor designs and layouts.

Hermann Fougner became an American citizen long before the war and joined heartily in the civic activities of Larchmont, N. Y., where he had resided for the last twenty years of his life. He was a member of the Ambulance Corps of the Larchmont Fire Department, and was elected a Trustee of the Village of Larchmont in April, 1931, which position he held until the time of his death.

He was a member of the Appawamis Club, the Larchmont Yacht Club, and the Engineers Club of New York, besides belonging to several fishing clubs and organizations for the preservation of game and fish.

Mr. Fougner's chief recreations were golf and fishing, but he was also fond of swimming and winter sports, in which he was naturally proficient from his early training in Norway.

He was a Licensed Professional Engineer in the State of New York, and was a member of the American Society for Testing Materials and the American Concrete Institute. He was also a Thirty-second Degree, Scottish Rite, Free Mason.

When Hermann Fougner, after fighting several weeks for his life, succumbed to an illness that developed from an accident, it was a great loss to his many friends in the engineering world. He was in the prime of life and had never been ill. His vigorous personality and alertness of mind invariably won him respect. His lovable character and unlimited capacity for friendship, endeared him to all with whom he came in contact. As an engineer and gentleman of lofty ideals and high principles his memory will long be cherished by his host of friends in all walks of life.

On February 13, 1903, at Colombo, Ceylon, Mr. Fougner was married to Stella Gray, of San Diego, Calif., who was touring the Orient. His one child, Frederikke, died at birth. He is survived by his widow, his sisters, Mrs. Elisabeth Hagen and Mrs. Annichen Aschehoug, of Oslo, Norway, and two brothers, Waldemar G. Fougner, a Consulting Engineer of Oslo; and Nicolay K. Fougner, M. Am. Soc. C. E., of New York City.

Mr. Fougner was elected an Associate Member of the American Society of Civil Engineers on February 1, 1905, and a Member on April 17, 1923.

JAMES HILLHOUSE FUERTES, M. Am. Soc. C. E.[1]

Died January 30, 1932

James Hillhouse Fuertes, the son of the late Estevan Antonio Fuertes, M. Am. Soc. C. E., long Dean of the College of Civil Engineering, Cornell

---

[1] Memoir prepared by Frank W. Skinner, M. Am. Soc. C. E.

University, and Mary Stone (Perry) Fuertes, was born at Ponce, Porto Rico, on August 10, 1863. He spent his boyhood in Ithaca, N. Y., where he prepared for college, and, in 1883, was graduated from Cornell University with the degree of Bachelor of Civil Engineering, at that time the highest engineering degree bestowed by the University for undergraduate work. From 1883 until 1926, when failing health limited his more strenuous activities, Mr. Fuertes' professional engagements, of increasing magnitude and importance, although most prominently featuring Sanitary and Hydraulic Engineering—investigations, design, and construction—included notable examples of other civil engineering activities. In 1895, Mr. Fuertes made an extended European tour, visiting and studying important sanitary works, meeting distinguished engineers, and collecting data which enabled him subsequently to solve numerous important technical problems in a notably broad and thorough manner.

From 1883 to 1891, Mr. Fuertes served, successively, as Assistant, and as Engineer, for the Department of Parks, New York, N. Y.; the Missouri, Kansas and Texas; the St. Louis, Fort Scott and Wichita; the Yates Center and Winfield; the Dodge City and Southern; and (builders of) the Camden and Alexandria Railroads. From 1891 to 1893, he was engaged in private practice at Camden, Ark., designing and constructing mill railroads, electric light plants, water-works, sewers, etc. Thereafter, for a short time at Ithaca, N. Y., and subsequently permanently at New York City, he continued in private practice, associated at intervals with other eminent engineers on important investigations and constructions. He made investigations, reports, and designs for more than forty cities, towns, and private owners on the collection, storage, purification, protection, extension, and distribution of water supplies, and supervised much of the construction. Among his clients for this work were the Cities of Brooklyn, N. Y.; Philadelphia, Pa.; Baltimore, Md.; Dallas, Tex.; Charleston, S. C.; Lynchburg, Va.; Harrisburg, Pa.; Cumberland, Md.; Camden, Ark.; Gloucester, Mass.; Princeton, and Plainfield, N. J.; Winnipeg, Man., Canada (including a large concrete aqueduct 100 miles long); Caracas, Venezuela; and many other towns, corporations, and individuals.

Mr. Fuertes also made investigations and designs for drainage, sewerage, and sewage disposal for more than forty cities, towns, institutions, and private owners, including the Cities of Chicago, Ill., Philadelphia, Pittsburgh, Pa., Newark, Elizabeth, Hackensack, Lakewood, Plainfield, and Hoboken, N. J., Honolulu, Hawaii, Ottawa, Ont., Canada, Caracas, Venezuela, and for Santos and Para, Brazil, where his very efficient sanitary work eliminated a terrible scourge of yellow fever.

He designed and supervised the construction of important viaducts in Fitchburg, Mass., Lynchburg, Va., and Harrisburg, Pa., all of which included important developments of construction, the latter applying for the first time the cantilever method of erection for long-span reinforced concrete arches, which, by ingenious utilization of the permanent reinforcement steel to resist temporary erection tensile stresses, eliminated falsework centers, and proved of great economic value.

Mr. Fuertes designed and constructed works that, since 1907, have completely protected the City of Harrisburg from floods that had previously damaged it. He was a member of the Board of the Miami Conservancy Commission that approved the flood-regulation works executed at a cost of many millions of dollars to protect the Miami Valley from inundations that had ravaged it; and he was retained to report on flood prevention in Buffalo, N. Y. In 1899, he reported to New York State on important canal improvements; and, in 1900, he designed difficult foundations in the Jersey Meadows for the Snead Iron Works, and improvements for the State Hospital, at Warren, Pa.

In 1902, he was retained to investigate the disastrous dynamite explosion in the Fourth Avenue Subway Tunnel, in New York City. In 1905, he reported on the Conoduiguinet Creek water power, and investigated the typhoid fever outbreak at Tome Institute. In 1906, he prepared plans and specifications for fire protection for, and lighting of, a large estate near Harrisburg, Pa. In 1909 Mr. Fuertes reported on a dam at Harrisburg; on the improvement of the Susquehanna River; on the sanitary works of the Manhattan State Asylum; and was a member of the Water-Works Arbitration Board for Parkersburg, W. Va. In 1910, he was a member of the New York City Metropolitan Sewage Committee. In 1916, he reported on incinerators to the Mayor of Atlantic City, N. J. In 1924, he superintended the reclamation of coal from the Susquehanna River for shipment to Denver, Colo., where it was advantageously used instead of sand in the 60 000 000 gal. per day water supply filter which he had constructed. Mr. Fuertes was the first to substitute anthracite coal for sand in filters working under very low-head losses; he used it for the Dallas, Tex., Water-Works plant, and in other filters, and it has been adopted by other engineers.

In 1924, he was a member of the Board of Review of the Sanitary District of Chicago that investigated the relation of the Great Lakes levels to Chicago problems.

At different times, Mr. Fuertes was associated with the late Rudolph Hering, M. Am. Soc. C. E, and the late Allen Hazen, M. Am. Soc. C. E., on sanitary works of great importance, and he was frequently retained in a consulting capacity on important engineering projects by cities, towns, corporations, and individuals, and often served as expert witness in litigation and as arbitrator of engineering disputes. His services were so satisfactory that he was retained again and again by many clients, who insisted on receiving his opinions and counsel after his failing health no longer permitted him to undertake strenuous responsibilities. During the last few years of his life, when he was obliged to relinquish arduous activities, he kept fully abreast of developments in his own technical field, and was frequently consulted on important sanitary and hydraulic matters.

Mr. Fuertes was the author of "Water and Public Health" (1897); "Water Filtration Works" (1907); "European Sanitary Engineering Series," published in 1897–1898 in *Engineering Record;* numerous monographs on sanitary and engineering subjects; many technical articles in *Engineering Record* and *Engineering News,* and contributions to the *Proceedings* and

Transactions of the Society. He was a member of the American Institute of Consulting Engineers; the Canadian Institute of Civil Engineers; the Pennsylvania Society of Civil Engineers; the American Waterworks Association; the American Civic Association; and the Engineers Club, of New York City.

He was of an investigating and studious disposition, with keen perception, sound judgment, broad vision, and unusual ability to analyze conditions and solve problems on economic considerations of construction, operation, and efficiency advantages. He was an able mathematician, computer, analyst, and designer; well posted in precedents and standard practice, and brilliant in his adaptation of them for the requirements of special conditions, and in supplementing them with new features. He had great and practical ingenuity, which he frequently applied to advantage in major improvements, in designing important details, and in overcoming unusual difficulties. He had unusual architectural and artistic abilities that enabled him to create beauty and dignity, combined with strength and efficiency, in structures where they are too often absent. Mr. Fuertes' original development of thin parabolic arches for sewer construction was arrived at well in advance of arch computations that were standard at the time his designs were prepared. He designed a new type of reinforced concrete hollow dam of inexpensive construction, which has since been patented by others, and which has successfully resisted heavy ice pressures and severe flood conditions for twenty years in the Susquehanna River, at Harrisburg.

His drawings, often made by himself with great skill and rapidity, were unusually complete and clearly detailed, and his specifications were models of fairness and thoroughness, leaving nothing in doubt. He was devoted to the interest of his clients; considerate of his employees; helpful to his associates; just and generous in his dealings with all; loyal to his profession and faithful to his public duties as a citizen.

In his death the Engineering Profession loses an eminent member, whose achievements marked substantial progress in design and construction of varied important works that reflected honor and credit to it; benefited many cities, communities, and individuals; were an inspiration to those associated with him; and will be an enduring memorial to him. Mr. Fuertes' experience, abilities, and sympathetic interest inspired confidence in all with whom he had dealings, and his gracious personality and warm friendships endeared him to his fellows.

Although suffering from increasing disabilities that for several years had prevented laborious activities, Mr. Fuertes was able to enjoy his home and his friends, reading, writing, and driving until a few hours before his death, passing away peacefully and painlessly. He is survived by his two sisters, Katherine Fuertes, of Aurora, N. Y., and Mrs. Sarah F. Hitchcock, of New York City, and by three step-children, Cornelius and Lucian Cable, and Mrs. Samuel Hart.

Mr. Fuertes was elected a Junior of the American Society of Civil Engineers on May 2, 1888, and a Member on February 6, 1895.

EDWARD GAGEL, M. Am. Soc. C. E.[1]

DIED FEBRUARY 11, 1931

Although much of the fixed physical property of The New York, New Haven and Hartford Railroad Company stands as a monument to the stewardship of Edward Gagel as its Chief Engineer, his personal modesty and dislike of anything which, as he saw it, savored of self-advertising were such that he could not be persuaded to contribute papers or even discussions to the publications of the several engineering societies to which he belonged, and the character of his work and his ability are fully known only to those who were closely associated with him.

A Civil Engineer of fifty-three years' active practice, forty-seven of which were with The New York, New Haven and Hartford Railroad Company, of which for twenty-four years he was Chief Engineer, Edward Gagel had retired from professional activities on October 1, 1929, and was just beginning to enjoy a well earned rest. During the greater part of his life his health had been excellent, but a heart affection which until his retirement had caused little concern, became progressively worse thereafter, and eventually resulted in his death.

Edward Gagel was born on October 25, 1858, in that portion of the present Borough of The Bronx, New York, N. Y., which then was the Village of Mount Hope. His parents, Christian and Anna M. (Aulinger) Gagel, had limited means, but gave their son a public school education, and he subsequently attended a course in Civil Engineering at Cooper Institute, in New York City.

At the age of 18, on June 16, 1876, Mr. Gagel began his professional career as Draftsman and Field Engineer for Dennis and Mairs, of New York City, a firm engaged in general surveying, and, for the next six years, he had a varied experience. Leaving this service in December, 1877, he was employed, successively, by the Brooklyn, Flatbush, and Coney Island Railroad Company until March, 1879; by the Metropolitan Elevated Railway Company of New York City until January, 1880; by the West Side and Yonkers Railway Company until March of the same year; on a location survey for the New York and New England Railroad Company (later a part of The New York, New Haven, and Hartford Railroad Company), looking to an extension to the Hudson River, until January, 1882; on location work for the Erie and Wyoming Valley Railroad Company for the next seven months; then for two months as Contractor's Engineer on the construction of the Pittsburgh, McKeesport, and Youghiogheny Railroad; and, finally, for three months, as Draftsman with The New York Central Railroad Company. This ended his wanderings; on December 6, 1882, he entered the service of The New York, New Haven and Hartford Railroad Company, and remained with it thereafter until his retirement from active service.

---

[1] Memoir prepared by Charles Rufus Harte and Clarence Blakeslee, Members, Am. Soc. C. E.

Progressing steadily, Mr. Gagel, successively, held the positions of Assistant Engineer; District Engineer in charge of the New York, the Naugatuck, and the Highland Divisions; Assistant Engineer in charge of the Western District; and Principal Assistant Engineer; until, on October 1, 1905, he was made Chief Engineer, which position he held until his retirement on October 1, 1929. On March 1, 1913, he was also appointed Chief Engineer of the Central New England Railway Company, holding this position until December, 1926, when by merger with the New Haven Company this subsidiary lost its separate existence; and on September 3, 1918, he also was appointed Chief Engineer of The New York Connecting Railroad Company, owned jointly by The New York, New Haven and Hartford and The Pennsylvania Railroad Companies, between which it forms a direct physical connection. This last position, Mr. Gagel held until his retirement from the Chief Engineership of the New Haven Company.

Mr. Gagel served the New Haven under eight of its Presidents, coming to it under Mr. George H. Watrous, who had inaugurated the policy of improvement and expansion so well carried out by his successors. In 1882, the property was only one of the twenty independent small roads of Southern New England, and had only 192 miles of line, a small portion of which was double-tracked; at the end of 1929 it comprised substantially all the transportation agencies—railroad, trolley, bus, and steamship—of its territory, the railroad proper having 2 225 miles of road, of which 114 miles were four-tracked, while 169 miles, much of which was four-tracked, and a little six-tracked, were electrified. Moreover, under the masterly personal direction of the then President, the late Edward J. Pearson, M. Am. Soc. C. E., there had been a complete re-organization of the facilities of the property, bringing it to high operating efficiency.

Edward Gagel had personal charge of part of the first four-tracking and improvement work on the New York Division, and, later, as Chief Engineer, directed the completion of this work and that of six-tracking the Harlem River Branch. Under his Chief Engineership the line from Stormville, N. Y., through Danbury to Shelton, Conn., and that from Waterbury to Bristol, Conn., were both double-tracked, the work including much line improvement, particularly at Terryville, where a tunnel 3 680 ft. long effected a notable grade reduction, these improvements giving a double-track freight line from Maybrook, N. Y., *via* New Haven, Conn., and Providence, R. I., to Boston, Mass., and, except for a stretch of 20 miles of single-track between Vernon and Willimantic, Conn., another double-track line between the same terminals *via* Hartford, Conn., and Willimantic. Two other very important improvements during this period were the widening of the east and west cuts through New Haven, eliminating a bad bottle-neck in the main line, and the construction of a direct line from Providence to East Providence, R. I., the mile-long tunnel by which this was carried under a residential section of Providence calling for particularly careful treatment.

The change to heavier motive power under the Pearson program necessitated a large number of clearance changes and bridge renewals. In addition to the many minor spans, there were a number of large openings, the treatment of which involved major engineering problems. Notable among these were the rebuilding, under and with practically no disturbance to its heavy traffic, of the great Hudson River Bridge, at Poughkeepsie, N. Y.; the construction of a new bridge over the Thames River, at New London, Conn.; of the Connecticut River Bridge at Saybrook, Conn.; the Housatonic River bridges at Stratford and at Sandy Hook, Conn.; and the bridges at Cos Cob, Niantic, and Westport, Conn., and over the Neponset River at Boston.

Major grade-crossing elimination projects were carried out at Attleboro, Clinton, Harrison, New Bedford, and Worcester, in Massachusetts, and at Pawtucket and Westerly, in Rhode Island; a large number of individual crossings were also eliminated, while many of those crossings remaining were equipped with automatic warnings, making the property in this respect one of the best protected of the American railroads.

Besides these improvements there were the construction or reconstruction of great freight yards at Cedar Hill, New Haven, at Hartford, at Harlem River, and at Northrop Avenue, Providence; car-float bridges at Oak Point, N. Y., in connection with the transfer of freight cars around New York City by water; repair shops at Readville, Mass., and Van Nest, N. Y.; and many other projects, comparatively small in each case, but making up a very large total.

In addition to the steam road work, Mr. Gagel had under his charge the engineering in connection with the secondary transportation facilities of The New York, New Haven and Hartford Railroad Company, involving the construction of nearly 100 miles of trolley lines of interurban type, and the electrification for trolley operation of about the same mileage of steam road tracks, together with the construction of the necessary power-houses, transmission lines, sub-stations, car-houses, and repair shops. The electrification of the New York Division for railroad operation did not come directly under the jurisdiction of the Chief Engineer, but many of the physical features necessarily came before him for approval, and his advice and assistance were availed of to a large extent.

On October 14, 1885, at her home in Dunmore, Pa., Mr. Gagel was married to Jennie Field Smith who, with two children, Anna Smith and David Edward, survives him.

Although, as stated, Mr. Gagel took little active part in the technical proceedings of his engineering societies, he always was greatly interested in their welfare and progress. He was a member of the American Railway Engineering Association, of the New York Railroad Club, and of The Connecticut Society of Civil Engineers, which latter Society elected him an Honorary Member on January 13, 1931. The formal presentation of the attesting scroll at the Annual Meeting had to be made posthumously, but, fortunately, Mr. Gagel had been advised of, and was able to appreciate, the honor before his death.

While Mr. Gagel was strongly opposed to publicity regarding his work, this reticence did not extend to informal discussion; he was ever ready to talk over his own problems or those of others with his friends or with any one who came to him for advice, and he was particularly pleased when he was able to help some young engineer. The energy and hard common sense which were so characteristic of his professional work, were made equally manifest elsewhere, and his services were constantly sought in many directions; but while always willing to assist behind the scenes, he consistently avoided any but the most necessary publicity, and in spite of urgent pressure refused to be drawn into political activities. He served as Chairman of the Building Committee of the First Congregational Church, of West Haven, Conn., of which Church he was also a Deacon and a Trustee; he was a member for twenty-five years of the Board of Education of West Haven; he had been President of its Park Board; a member of its Paving Commission and of its Village Improvement Society; and, for four years, Chairman of its Fire Board. For many years, too, he was a member of the New Haven Harbor Commission, of which for six years he was President; he had long been a Director of the West Haven Bank and Trust Company, and he was active in several other business affairs.

A member of Trumbull Lodge, A. F. and A. M., Mr. Gagel was a Knight Templar, a Thirty-second Degree Mason, and a Shriner. He belonged to the Engineers Club of New York, and to the Union League and to the Racebrook Country Clubs of New Haven. An independent in politics, in religion he was a Congregationalist. Of fine presence and genial disposition, he easily made and held many friends who enjoyed his whimsical philosophy no less than his sympathetic attitude, while his kindly disposition made him an anchor to windward for many an unfortunate. His loss will be felt deeply in many directions.

Mr. Gagel was elected a Member of the American Society of Civil Engineers on April 3, 1907.

BENJAMIN HURT HARDAWAY, M. Am. Soc. C. E.[1]

DIED DECEMBER 13, 1928

Benjamin Hurt Hardaway was born at Valumbrosa, near Union Springs, in Bullock County, Alabama, on February 19, 1866. He was the son of Colonel Robert Archelaus and Rebecca Elizabeth (Hurt) Hardaway, parents of unusual strength of character, who through precept and example instilled in their children the highest principles of integrity. Benjamin Hurt Hardaway was one of three sons, his two brothers being Robert Early and George Stanfield Hardaway.

Mr. Hardaway's grandfather, Major Robert Stanfield Hardaway, had been President of the Mobile and Girard Railroad Company (in Alabama), and his father, Superintendent and Chief Engineer of the same railroad, before the Civil War. Colonel Hardaway had served as a Captain in the

---

[1] Memoir prepared by Frederick C. Ray, Assoc. M. Am. Soc. C. E.

Mexican War, and, in the Civil War, he was a Colonel of Artillery. About 1869, or 1870, he and his family moved to Opelika, Ala.; later, to LaFayette, Ala.; and then to Auburn, Ala. During this period, he was Chief Engineer and Superintendent of the East Alabama and Cincinnati Railroad, and, later, was Professor of Engineering, and Commandant, at the Alabama Polytechnic Institute. Some years later, Colonel Hardaway moved to Tuscaloosa, Ala., where he was Professor of Engineering at the University of Alabama.

During this period, Benjamin Hurt Hardaway was receiving his education. He was a student through his Sophomore year at the Alabama Polytechnic Institute, at Auburn, and at the University of Alabama, in 1883, from which he received the degree of Bachelor of Science; in 1884, the degree of Bachelor of Engineering; and, later, the degrees of Master of Arts and Civil Engineer. From 1884, to 1886, he was Assistant Professor of Mathematics at the University of Alabama. While teaching, he found time to devote to engineering pursuits, acting as City Engineer for the City of Tuscaloosa. In that capacity he designed and constructed works on the streets paralleling the Warrior River, for protection against erosion. In that early period, he wrote an Engineers' Handbook.

In 1886 and 1887, Mr. Hardaway was Assistant Chief Engineer of the Savannah, Americus and Montgomery Railroad, on construction work west of Lumpkin, Ga., working under his brother, Robert Early Hardaway, who was Chief Engineer. In 1887, the latter resigned, to enter other work, and Benjamin Hurt Hardaway, then less than 21 years of age, was promoted to the position of Chief Engineer. He continued the location and construction of the line between Americus and Abbeville, Ga., toward Savannah, Ga. Sixty miles of railroad and various bridges were built under his direction during this period.

In 1888, he left the service of the Savannah, Americus and Montgomery Railroad Company (afterward the Seaboard Air Line Railway Company) and became Division Engineer on the Chattanooga, Rome and Columbus Railroad, then under construction north of Rome, Ga. Later, he was Chief Engineer of Surveys for the East Alabama Railroad Company. Finishing this work in 1888, Mr. Hardaway went to Carrollton, Miss., where he was engaged as Resident Engineer, on construction, for the Southern Railroad Company, later, becoming Track Engineer. From Carrollton, he went to Gordon, Ala., as Resident Engineer for the Alabama Midland Railway Company (now the Atlantic Coast Line Railway Company) and, in this capacity, directed the construction of a bridge over the Chattahoochee River at Alaga, Ala., and fourteen miles of track on the west side of the river. This was the first of a number of bridges he built over the Chattahoochee. In 1890, he was promoted to the position of Assistant to the Chief Engineer, on this railroad.

From Gordon, Mr. Hardaway went to Ozark, Ala., and served as Assistant Chief Engineer on the extension of the line from Montgomery to Tuscaloosa, for the Montgomery, Tuscaloosa, and Memphis Railroad Company. In January, 1890, and until August of the same year, he was working near Maplesville, Ala., on this location.

About July, 1890, Mr. Hardaway returned to the service of the Savannah, Americus and Montgomery Railroad Company, as Assistant to the Chief Engineer and as Assistant Superintendent of the Georgia and Alabama Construction Company. He directed much field relocation from Louvale, Ga., to Montgomery, and was in special charge of the construction of the new drawbridge over the Chattahoochee River, at Jernigan, Ala. At this time, the severe financial panic of 1891 and 1892 was being felt and the Savannah, Americus and Montgomery Railroad Company went into the hands of a receiver; Mr. Hardaway, however, continued with the construction at Jernigan, and the bridge was completed in 1892. While with the Railroad Company, Mr. Hardaway and his brother, Mr. R. E. Hardaway, selected, bought, and laid out the Towns of Cordele and Helena, Ga.

The year 1891 marked a turning point in the career of Mr. Hardaway. Apparently, he had come to the conclusion that his efforts in the future would be along the lines of construction as a general contractor. He operated gravel pits at Americus, Ga., selling ballast to the Savannah, Americus, and Montgomery Railroad Company, and contracted for the construction of depots and section houses. He then contracted for the construction of all pile-driving and trestle work on the Savannah, Americus, and Montgomery Railroad from the Chattahoochee River to Fort Davis, Ala., and for a Y-trestle in the railroad yards in Montgomery.

Returning to Mississippi, in the spring of 1892, he entered into contract with the County of Carroll to erect numerous steel bridges throughout the County. This work was completed by fall and he then took contract for the construction of trestles between the Satilla River and the St. Mary's River, for the Florida-Central and Peninsular Railroad Company, near St. Mary's, Ga. During this year he also built a bridge over the St. Mary's River for this Company.

During 1892 and part of 1893, Mr. Hardaway was engaged in railroad construction work for the Atlantic Coast Line Railroad Company in South Carolina. In the latter part of 1893, he built the Belt Line Railroad through Petersburg, Va., the project including two treated wood-pile bridges with steel decking. He later constructed the Presbyterian Church in Rock Hill, S. C.

In 1894, he built eighteen miles of railroad between Seivern, and Batesburg, S. C., this line now being part of the Southern Railway. During the same year, he built the Louisville and Nashville Railroad Extension from Cusseta, to Prattville, Ala. While this work progressed, he contracted for a short railroad and bridge for the W. C. Alverson Saw-Mill, near Moselle, Miss. During this same year, he also built the pivot pier in the Warrior River at Tuscaloosa. This was for the highway bridge over the river and was built under a contract with Tuscaloosa County. At Montevallo, Ala., he removed an old wooden structure over the creek and replaced it with a steel bridge.

During 1895, Mr. Hardaway was interested in the construction of a dam and power house project for the Anderson Water, Light, and Power Company at Anderson, S. C., which was one of the first hydro-electric plants in the

South; a combination railroad and highway bridge over the Tallapoosa River, at Tallassee, Ala.; and various kinds of trestle work in Georgia. In 1896, his works were confined to railroad and bridge construction in the States of Georgia and Alabama. In 1897, continuing as an active contractor, and building with the South, Mr. Hardaway contracted for and built a dam and power house on the Yadkin River near Winston-Salem, N. C. This work was for the Winston-Salem Power Company; and, in 1898, he was interested in the construction of piers, head-gates, trestles, dams, power houses, etc. In 1899, Mr. Hardaway built a dam and power house at North Highlands, near Columbus, Ga., for the Columbus Power Company; a highway bridge at Fosters Ferry, on the Warrior River, between Tuscaloosa and Eutaw, Ala.; and a railroad from Searight, to Andalusia, Ala., for the Central of Georgia Railroad Company.

Beginning the Twentieth Century as a man 34 years of age, Mr. Hardaway had seen the completion of numerous projects with which he had been associated. In some of this work he was in partnership with Mr. B. O. Watkins, of Birmingham, Ala. His friends, clients, and associates recall with pleasure these earlier years in their dealings with him. "Honesty, Integrity, and Responsibility" was his motto from the very first contract. A job contracted for was a responsibility acquired, that had to be carried out, regardless of profit or loss.

In 1901, he executed contracts for the Central of Georgia Railroad Company, building a line from Columbia, to Coffee Springs, Ala. From 1901 to 1908, he was interested in and completed the construction of as many as thirty-two contracts throughout the States of Georgia, Florida, Alabama, Virginia, Mississippi, South Carolina, and Tennessee. In 1908, Mr. Hardaway signed a contract with the Southern Power Company for the construction of a dam and power house on the Broad River, at 99 Islands, near Blacksburg, S. C. In 1909, he entered into a contract with the Columbus Power Company for the construction of the dam and power house at Goat Rock on the Chattahoochee River above Columbus, Ga., and, in the same year, contracted with the United States Government for building Lock No. 16 on the Warrior River above Tuscaloosa. In the following year, he contracted with the Government for building Lock No. 17, just above Lock No. 16, and also entered into contract with the City of Columbus, for a bridge at Dillingham Street.

In 1911, Mr. Hardaway realized that his contracts were assuming large proportions for an individual, so, taking men who for years had been with him, he organized the Hardaway Contracting Company, a Georgia corporation. He was elected President of the Company and directed its activities until his death, on December 13, 1928. Mr. Hardaway was actively associated with the planning and carrying out of each and every one of the sixty-seven projects undertaken by his firm to that date and gave careful thought to all. Among these projects, and worthy of mention, were four hydro-electric developments for the Southern Power Company and subsidiaries in the Carolinas; three cantonments for the United States Government; two hydro-electric developments for the Georgia Power Company; two hydro-electric developments in North Carolina for the Aluminum Company of America; one hydro-electric development for the Carolina Power and Light Company, in North Carolina; besides seventeen concrete highway bridges for the States of North Carolina, South Carolina, Alabama, Georgia, Florida, and Tennessee. At the time of his death, his men were carrying out numerous works that had been planned by him.

With all his many activities, Mr. Hardaway never failed to discharge fully his civic and religious duties. He was a member of the Methodist Episcopal Church, serving as Steward for many years, and was ever a generous supporter not only of his church, but of all deserving causes brought to his attention. He held the respect, confidence, and affection of his fellows to a remarkable degree.

Concerning Mr. Hardaway a few days after his death, Mr. W. C. Woodall, a columnist of the Columbus *Enquirer-Sun,* wrote:

> "Mr. Hardaway was great as an engineer and builder. He was great as one of the outstanding figures in the development of his section of the country. * * * He was great in his high conceptions of business honor, and in the strict integrity which marked all big transactions. But he was greatest as a gentleman.
>
> "He was one of Nature's noblemen. There are some to whom the qualities of gentility are so inherently native that we accept them as such without wonder. Mr. Hardaway was instinctively and intuitively a gentleman. The memory of his courtesy, his modesty, his gentleness of manner and his perfect consideration of others will never fade from the hearts of his friends.

* * * * * * * * * * * *

> "He was distinguished in his field as an engineer, and builder; as a business man he was successful in unusual degree, and yet it is on his purely personal qualities that the memories of his friends linger most fondly. * * *."

Mr. Woodall has written ably and well of the feelings and thoughts of Mr. Hardaway's friends and associates toward him and little more can be said; however, it seems fitting to mention his attitude toward the men on his "jobs." On visits to his contracts and as he looked over the work, deep in thought, he was never too occupied, or too busy, to stop and speak with those with whom he had become personally acquainted; his hand was first to go out in welcome, whether to water boy, foreman, engineer, or superintendent. He liked to listen to the ideas and suggestions of those under him, no matter how radical or how impractical, and he would try to ferret out the reasonings behind the thought. His men were inspired by his thorough interest in every problem, large or small. He was the last to stop work; the first to begin. He would often say, "A contractor's profits depend not on how much he makes on any one contract, but on how well his clients are satisfied." This was the guiding advice to his organization.

On September 14, 1888, he was married to Rebecca Money, at Carrollton, Miss., who, with one son, Benjamin Hurt Hardaway, Jr., Assoc. M. Am. Soc. C. E., and a brother, Robert Early Hardaway, survives him.

Mr. Hardaway was elected a Member of the American Society of Civil Engineers on October 7, 1903.

JAMES CLARK HARDING, M. Am. Soc. C. E.[1]

Died November 16, 1927

James Clark Harding was born in Pittsfield, Mass., on September 28, 1873, the son of James Harding and Mary (Clark) Harding. His parents came from England, and his father was a well-known newspaper man who for many years published and edited a newspaper in Pittsfield.

Mr. Harding was educated in the public schools of his native city and after finishing his High School course became an Assistant to the late Mr. Ernest W. Bowditch on the construction of the Pittsfield Sewerage System. From 1896 to 1906, he was Assistant City Engineer of Pittsfield, in charge of the design and construction of sewer extensions and of highway and water-works improvements. In 1902, under the direction of Mr. J. J. Van Valkenburgh, he was in immediate charge of the intermittent sand filter plant of Pittsfield and the associated sewage pumping station.

In 1906, Mr. Harding came to New York, N. Y., as a member of the staff of Hering and Fuller for five years, after which, for three years, he was a partner in the firm of George W. Fuller. From 1913 to 1917, he was engaged in private engineering practice and afterward was associated with the firm of Fuller and McClintock, until July, 1927, when he again established his own engineeering practice.

His work was principally in the fields of sewerage, sewage disposal works, water-works, and the valuation of public utilities. His best known work related to the Imhoff tank and sprinkling filters at Schenectady, N. Y.; the activated sludge plants at Mamaroneck, N. Y., and Tenafly, N. J.; the betterments to the sewerage system and the sewage disposal works for the General Electric Company, at Pittsfield and at Schenectady; the water filtration plant and extensions to the water-works system at Newburgh, N. Y.; the sewerage system and sewage treatment works at Glen Cove, Long Island, N. Y.; and the screen plants at New Rochelle, N. Y., and Bridgeport, Conn. He also collaborated in the preparation of numerous preliminary reports and designs in the fields of water supply, sewerage, and sewage disposal.

Mr. Harding was a diligent student of engineering practice and was widely read, not only on matters pertaining to sanitary engineering, but also to valuation of water-works properties. His work in this field, while connected with Fuller and McClintock, covered co-operation on the valuation of the New York Interurban Water Company, in Westchester County, New York; the Springfield Consolidated Water Company property, now the Philadelphia Suburban Water Company; the New Chester, Pa., Water-Works Company; and the Bluefield, W. Va., Water-Works Company.

In the sanitary field, his work covered surveys in connection with the investigation of typhoid fever epidemics at Cooperstown, N. Y., Des Moines, Iowa, Wilkes-Barre, Pa., etc.

---

[1] Memoir prepared by George W. Fuller, M. Am. Soc. C. E.

Mr. Harding's gifts as to clarity of expression, both orally and in writing, were of a high order and doubtless were influenced by his father. Combining this characteristic with his excellent executive ability, untiring efforts, and keen insight into human nature, he was more than ordinarily successful in carrying forward his undertakings in the field of public works. He was a member of the Masonic Order.

Mr. Harding was killed near South Canaan, Conn., in an automobile accident, in which his son, Joseph Buckley Harding, also lost his life. He is survived by his widow, Sarah Palmer Harding, and four sons, the eldest of whom, James Clark Harding, Jr., Assoc. M. Am. Soc. C. E., succeeded to his father's engineering practice with offices in New York City.

Mr. Harding was elected a Member of the American Society of Civil Engineers on January 2, 1912.

EDWARD WILLARD HOWE, M. Am. Soc. C. E.[1]

Died June 27, 1931

Edward Willard Howe, the son of William and Catherine (Willard) Howe, was born in Braintree, Mass., on August 27, 1846. He attended the public schools of Braintree and was graduated from Middlebury College, Middlebury, Vt., in 1869.

In 1874, Mr. Howe was appointed Assistant Civil Engineer for the City of Boston, Mass., which position he held until 1914. While serving in this capacity in the office of the City Engineer, he had a large and varied experience.

From 1883 to 1887, Mr. Howe had charge of the engineering work on Franklin Park, Bussey Park, Back Bay Park, Marine Park (Iron Pier and Castle Island Bridge) and Wood Island Park. As Engineer in Charge of Park Construction and Maintenance he continued on this work from 1887 to 1897, in addition to that on Franklin Field, Arborway, Jamaica Park, Leverett Park, Riverway, Dorchester Way (later, part of Columbia Road), Strandway (sea wall and filling), Charlestown Heights, Charlestown Playground, North End Park, Charlesbank (between Cambridge and Leverett Streets), Neponset Playground, and others. About 1897, a Superintendent of Parks was appointed by the Park Commissioners, but Mr. Howe continued to attend to the park engineering until early in 1898, when this work was taken out of the City Engineer's Office.

In 1898, he was placed in charge of building the Ipswich Street Bridge, in Boston, over the Fens Waterway, the Charlesgate West Bridge, over Ipswich Street, and the Columbia Road filling, in South Boston. About 1899, and later, he constructed the Columbia Road Bridge over the tracks of The New York, New Haven, and Hartford Railroad, and over Shoreham Street, and was in charge of work in connection with the abolition of the Dorchester Avenue grade crossing, including the bridges and streets at Dorchester Avenue, and Boston and Southampton Streets.

---

[1] Memoir prepared by Edgar S. Dorr, and Frank O. Whitney, Members, Am. Soc. C. E.

About 1901, Mr. Howe had charge of building the Broadway Bridge over Fort Point Channel, as well as the Atlantic Avenue Bridge over the railroad tracks near the South Station, Boston, and over Fort Point Channel. About 1905, he constructed the temporary bridge at Brookline Street (Cambridge), over the Charles River, and was in charge of work on the abolition of grade crossings, in East Boston, on the Boston and Albany Railroad. In 1907, the building of the boundary wall and the sea wall on Deer Island was entrusted to him.

From 1907 to 1914, Mr. Howe was engaged upon the sewerage system and surface drainage and road building for the Consumptives' Hospital, at Mattapan, Mass.; in 1909, he made many plans and estimates of schemes for the abolition of grade crossings on The New York, New Haven, and Hartford Railroad, in the Harrison Square District, of Boston; and, in 1910, he had charge of the addition to the Dorchester Avenue Bridge over the Shawmut Branch of The New York, New Haven and Hartford Railroad, at Ashmont, Mass.

In 1911, when the Public Works Department of the City of Boston was organized, Mr. Howe was appointed Engineer of Grade Crossings and Special Work. From 1911 to 1914, he was engaged on the abolition of grade crossings on the Boston, Revere Beach, and Lynn Railroad, in East Boston; and, in 1912, he designed and had charge of the construction of the Lawnsdale Terrace Subway under the Providence Division of The New York, New Haven, and Hartford Railroad.

In 1913 and 1914, he made surveys, plans, and specifications for rebuilding the Winthrop Bridge, between East Boston and Winthrop, Mass. His work included also many smaller jobs called for by the various Departments, which were done by the Engineering Department under his direction, until his retirement from active work about 1916.

In 1900, Mr. Howe became President of the Merchants' Co-Operative Bank of Boston (Director from 1884 to 1900, and President from 1900 to 1918). He was a member of the Boston Society of Civil Engineers, which he joined on January 8, 1874, and served as President in 1907. He joined the Appalachian Mountain Club in 1895, and was Vice-President in 1901 and President in 1902.

For more than fifty years he was a member of the Sons of the American Revolution, maintaining an active interest in the Boston Chapter. He was also a member of the New England Genealogical Society for many years. In religion, he was a member of the Unitarian Denomination and was especially interested in All Souls Church, of Roxbury, Mass.

Mr. Howe was throughout and invariably a mild, calm, and courteous gentleman under any and all circumstances.

On April 29, 1880, he was married to Addie E. Newell. He is survived by his widow and three nephews.

Mr. Howe was elected a Member of the American Society of Civil Engineers on September 7, 1887.

ANDREW MURRAY HUNT, M. Am. Soc. C. E.[1]

Died December 8, 1930

Andrew Murray Hunt, the son of Andrew Murray and Marion (Kent) Hunt, was born at Sioux City, Iowa, on August 12, 1859.

Mr. Hunt received his technical education at the United States Naval Academy, Annapolis, Md., from which he was graduated in 1879. While in the Navy he was Engineer Officer on several vessels; served as Instructor in Mechanical Engineering at the Orchard Lake Military Academy for a year; was a member of the Naval Steel Inspection Board, having charge of chemical inspection; organized the Chemical Laboratory at Mare Island Navy Yard; and was, for a time, Chief Engineer on the U. S. Fish Commission's Steamer, *Albatross*.

He remained in the Engineering Corps of the United States Navy until 1894, when he resigned to take up private practice. In 1893 he had been granted leave in order that he might serve the Midwinter Fair at San Francisco, Calif., as Chief of its Mechanical Department. His success in introducing novel effects of fountain and tower lighting attracted much attention at that time. Mr. Hunt's resignation from the Navy followed this engagement, and he then became active mainly on electrical projects as a member of the firm of Hasson and Hunt, of San Francisco. This firm began its activities at a time when electrical engineering was scarcely out of its infancy.

As a member of this firm, Mr. Hunt was Consulting Engineer to the Folsom Water Power Company, and to the Los Angeles Railway Company, on the problem of changing cable roads to electric roads. He also designed and installed an 800-kw. hydro-electric plant for the Nevada County Electric Power Company which for a time included the longest transmission line in the world; this line which, to-day, would be considered very short, was remarkable for its time, and, from the first, supplied the power necessary for operating the mines about Nevada City, Nev. This plant proved to be the beginning of the great system of the Pacific Gas and Electric Company. Mr. Hunt also designed and constructed an hydro-electric plant for the Victoria Electric Power Company.

In 1898, he was called to Alaska where he built four steamers for the Alaska Commercial Company. He was thereafter Consulting Engineer on various projects, such as the Northern California Power Company, the Truckee River General Electric Company, and the Vancouver Power Company, Limited, of Vancouver, B. C., Canada, a notable feature of which was a water tunnel 13 000 ft. long.

When Mr. Claus Spreckels decided that there should be competition with the established gas company at San Francisco, his selection of Manager and Chief Engineer fell upon Mr. Hunt who took personal charge, planned, and installed a successful competitive system at a cost of about $4 500 000 which, however, was taken over by the old company some years later.

---

[1] Memoir prepared by a Committee of the San Francisco Section, consisting of C. E. Grunsky, Past-President, Am. Soc. C. E., and H. L. Haehl and W. L. Huber, Members, Am. Soc. C. E.

Mr. Hunt removed from San Francisco in 1915, establishing himself in New York, N. Y., where he was a member and President of the Peyton Hunt Company, Incorporated, Consulting Engineers. The breadth of his activities and interests is indicated by the fact that he was also President of the Granton Chemical Company and a Director of the Western Pacific Railroad Corporation. During the World War he was a member of the Naval Consulting Board and also of the Ship Protection Committee of the United States Shipping Board. He had unusual skill in perfecting mechanical devices, one illustration of which is a mechanical locomotive stoker now in widespread use. His mental precision, combined with his absolute fairness, caused his services to be much sought in connection with litigation and also as an arbitrator.

When Mr. Hunt had reached a conclusion on any subject or problem there was a positiveness about his presentation thereof which was impressive and could not fail to carry conviction. He understood his subject and could be depended upon to present its aspects fairly. As a member of the Board of Direction of the Society he endeared himself to all his associates, generally taking but little part in the discussions, but at the proper time coming forward with a solution of some involved matter satisfactory to all.

Mr. Hunt was, as appears from this brief record of his activities, a highly trained, able, and conscientious member of the Engineering Profession, untiring in the interest of his clients, and a citizen of the highest type. In his death, which occurred at Berkeley, Calif., on December 8, 1930, the profession lost a most valuable member.

He was a member of the American Society of Naval Engineers; the American Society of Mechanical Engineers; the American Institute of Electrical Engineers; and the American Electrochemical Society. He was unmarried.

Mr. Hunt was elected a Member of the American Society of Civil Engineers on February 7, 1906. He served as a Director of the Society from 1918 to 1920, inclusive, and as Vice-President in 1921 and 1922.

EDGAR JADWIN, M. Am. Soc. C. E.[1]

DIED MARCH 2, 1931

Edgar Jadwin was born at Honesdale, Pa., on August 7, 1865, the son of the Hon. Cornelius C. Jadwin and Charlotte E. (Wood) Jadwin. His father served as a member of Congress from Pennsylvania, from March 4, 1881, to March 3, 1883. The son attended the public schools in Honesdale and entered Lafayette College, at Easton, Pa., in 1884. He completed the Freshman year and half the Sophomore year in the General Scientific Course, but left college on account of receiving an appointment to the United States Military Academy. He entered West Point on July 1, 1886, and was graduated therefrom on June 12, 1890, at the head of his Class.

---

[1] Memoir prepared by Herbert Deakyne, M. Am. Soc. C. E.

On his graduation, Cadet Jadwin was commissioned an Additional Second Lieutenant in the Corps of Engineers, and rose steadily through all the grades, to that of Colonel on September 10, 1919. On June 19, 1924, he was detailed as Assistant Chief of Engineers, with the rank of Brigadier General, and on June 27, 1926, as Chief of Engineers with the rank of Major General. He was placed on the retired list on August 7, 1929.

When war with Spain began, he was a First Lieutenant. He was commissioned as Major in the Third U. S. Volunteer Engineers, June 20, 1898, and as Lieutenant-Colonel in that regiment, September 15, 1898, serving as such until he was mustered out, on May 17, 1899. At the outbreak of the World War, he was advanced from his regular rank of Lieutenant-Colonel to the temporary rank of Colonel in the National Army, July 6, 1917, and to the temporary rank of Brigadier General, December 17, 1917, from which he was discharged November 1, 1919.

The first duty of Edgar Jadwin in his long and active career as an Engineer Officer was as Assistant to Capt. Thomas L. Casey, Corps of Engineers, U. S. A., in New York, N. Y., where he served as Senior Inspector on the enlargement of the site of the Immigration Station at Ellis Island, from August, 1890, to February, 1891. He then went to the Engineer School of Application at Willets Point, now Fort Totten, New York, to take the post-graduate course, and was graduated from this school in 1893. He was detailed as Quartermaster of the Battalion of Engineers in March, 1893, and continued on this duty until October, 1895. He was then engaged on river and harbor improvement and fortification work at Wilmington, N. C., as Assistant to the District Engineer, and remained on this duty for two years. In October, 1897, he was transferred to the Office of the Chief of Engineers in Washington, D. C., where he served as an Assistant in the Fortification Section of that Office.

After war with Spain was declared, as an officer of the Third U. S. Volunteer Engineers, Major Jadwin enlisted recruits for the regiment in Texas, Arkansas, and New Mexico, during June and July, 1898, and served with it in Missouri, Kentucky, and Georgia until December, 1898, when he went to Cuba, where he commanded a battalion of the regiment at Matanzas until the end of February, 1899. This Battalion raised the American flag at Matanzas on January 1, 1899, made a reconnoissance of the Province of Matanzas, and constructed camps, roads, water supply systems, a target range, and a dock. It also cleaned the streets and improved the sanitary conditions of the city. In March, 1899, Lt.-Col. Jadwin returned to the United States on account of illness, and was in the hospital and recuperating until the end of August. He then went on duty at New York as Recorder and Disbursing Officer of the Board of Engineers. At that time this Board was composed of three of the Senior Officers of the Corps of Engineers and was charged with the planning and development of the sea-coast fortifications of the United States. Its duties were of the greatest importance to the National defense and its work was of high interest from the technical and professional standpoint of the military engineer. He had charge of the designing force and the preparation of the reports of the Board.

Captain Jadwin remained on this duty until March, 1902, when he went to Los Angeles, Calif., in charge of river and harbor improvements and fortification work in Southern California. In June, 1903, he was transferred to Galveston, Tex., and placed in charge of this large and important district. In connection with the fortification work at Galveston, Captain Jadwin had charge of the building of the sea-wall at Fort Crockett, as a part of the comprehensive plan for the protection of Galveston against a recurrence of such a disaster as occurred in the hurricane of 1900.

His next duty was one of prime importance. He was selected as one of the Engineer Officers on the construction of the Panama Canal and took up this work in July, 1907. His first detail was as Division Engineer of the Chagres Division, engaged in dredging and straightening the Chagres River. On July 1, 1908, he became Resident Engineer of the Atlantic Division, Harbor and Channel Section, and took charge of the excavation of the sea-level section on the Atlantic side; the construction of the Colon breakwaters; the supply of broken stone and sand for lock and dam construction; and the operation of harbor dredges, dry docks, floating-plant repair shops, and sea-transportation plant. He continued on the Panama Canal work until August, 1911, when he returned to the United States, and for the short period from October to December, 1911, had charge of the Nashville Engineer District. He was then called to the Office of the Chief of Engineers, in Washington, where he organized a new section, the important Miscellaneous Civil Section, which passes on bridge plans and applications for authority to build structures in navigable waters, handles the removal of wrecks, and supervises various other minor activities.

Following this duty he was transferred, in June, 1916, to Pittsburgh, Pa., where he had charge of the improvement of the upper part of the Ohio River and of its tributaries in the vicinity of Pittsburgh. He was a member of the Ohio River Board which handled the questions pertaining to the great canalization project on the Ohio.

Lt.-Col. Jadwin was at Pittsburgh when the United States entered the World War. One of the first steps in the war was the organization of nine regiments of railway troops for early service in France, and he was selected to organize and command one of these regiments, known first as the 5th Reserve Engineers and, later, as the 15th Engineers (Railway). He proceeded to organize this regiment in May and June, 1917. The regiment was the first of the nine to sail for France, on July 9, 1917. It landed at Liverpool, England, on July 19, and at Le Havre, France, on July 26. This regiment had the distinction of being the first American regiment to pass through England under arms. In France, the regiment was stationed at Gievres, where it entered upon construction work and the selection of sites for depots and other facilities. Gievres became one of the greatest supply depots of the American Expeditionary Forces. The fall of 1917 was spent in the construction of row after row of storehouses and the necessary railway tracks to serve them, and in the receipt, storage, and issue of property and equipment.

On December 17, 1917, Colonel Jadwin was promoted to the rank of Brigadier-General in the National Army, and on February 17, 1918, was transferred to Langres as Chief Engineer of the Advance Lines of Communication. After a month at Langres he was ordered to Chaumont, the General Headquarters of the American Expeditionary Forces, where he became Director of Light Railways and Roads, on March 19, 1918. This duty lasted until May 23, 1918, when he went to the Headquarters of the Service of Supply, at Tours, as Director of Construction and Forestry. Here, he made his great contribution to the war. His work included the construction of docks, railroads, roads, barracks, hospitals, depots, bakeries, cold storage plants, machine shops, power plants, aviation fields, water supply, sewerage, oil and gasoline storage, and the management of forestry operations for the production of lumber. At the height of its activity, his command included 160 000 men.

After the conclusion of the war, these operations were gradually curtailed. General Jadwin was detailed in July, 1919, as a member of the American Mission to Poland and, later, as an observer in the Ukraine, to deal with post-war conditions in those sections of Europe. He returned to the United States in November, 1919, and resumed his regular rank of Colonel in the Corps of Engineers on November, 1919. He was assigned to duty as Engineer of the 8th Corps Area at Fort Sam Houston, San Antonio, Tex., and remained on that duty from February, 1920, to July, 1922. One of the principal activities of his office during that period was the mapping of sections of the Mexican Border. He was a member of the Board that prepared the project for flood control in the San Antonio River. It is noteworthy that during his tour in San Antonio one of the large floods of the Mississippi River occurred, and that, on his own initiative, Colonel Jadwin made a visit to the lower part of the Mississippi Valley to observe this flood. This was in 1922 and is significant in view of the events which occurred five years later.

In July, 1922, he was transferred to Charleston, S. C., where he took up the duties of District Engineer of the Charleston District and Division Engineer of the Southeast Division. His work covered the important sections of the Intracoastal Waterway along the South Atlantic Coast and the leading harbors in the States from North Carolina to Florida. This duty continued for only two years. On June 19, 1924, Colonel Jadwin became Assistant Chief of Engineers, with the rank of Brigadier General. During the period that he held this position, he was Senior Member of the Board of Engineers for Rivers and Harbors, handled the river and harbor activities in the office of the Chief of Engineers, and served on various boards, among them one of international importance, the Joint Board of Engineers on the St. Lawrence River.

General Jadwin became Chief of Engineers with the rank of Major General on June 27, 1926, and continued in that position until August 7, 1929.

He retained his position on the Board of Engineers on the St. Lawrence River, which submitted its report in November, 1926. During the first year of his incumbency as Chief of Engineers, occurred the great flood of 1927 in the Mississippi River. Secretary Hoover and General Jadwin visited the scene of the flood together and issued a joint statement regarding the flood and the principles upon which a plan should be based for preventing the recurrence of such a catastrophe. General Jadwin considered the time ripe for an attempt to lay down a project for the Mississippi River which would put an end to the menace of periodical floods. He spent a large part of his time during the summer and fall of 1927 on this problem. He visited the Valley repeatedly; he set in motion an intensive study of the records of past floods; he caused investigations to be made throughout the Mississippi water-shed to determine the feasibility of different methods of flood control; and he spent laborious days and nights in going over records and plans with the best talent at his command among the officers and civilian engineers in the Corps of Engineers and the Engineer Department. The result was his report submitted on December 1, 1927, embodying what has since been called the "Jadwin Plan" for the control of Mississippi River floods. Briefly, the plan proposed the strengthening of the existing levees, progressive revetment of caving banks, improvement of the channel by dredging and by contraction works, a controlled spillway just above New Orleans, La., and three floodways, one from Cairo, Ill., to New Madrid, Mo., one from the Arkansas River through the Tensas Basin to the Red River, and one from the Red River through the Atchafalaya River to the Gulf of Mexico. The cost of the work proposed was about $300 000 000. The plan aroused much controversy, but after protracted hearings and debates it was adopted by Congress in the Act approved May 15, 1928.

General Jadwin continued in service long enough to inaugurate the work under this plan and to see it in process of vigorous execution. He reached the age of 64 years on August 7, 1929, when, according to law, he passed to the retired list. By virtue of an Act of Congress passed in 1915, he was advanced one grade in rank upon retirement on account of his service in connection with the construction of the Panama Canal. This made him a Lieutenant General, one of the few men in American history who have reached that rank.

During his service as Chief of Engineers, General Jadwin was Chairman of the National Capital Park and Planning Commission, created in 1924 to deal with questions relating to streams, forests, and other natural scenery in and about Washington, and to develop the Park and Playground System. He was also a member of the Board of Commissioners of the United States Soldiers' Home.

After his retirement, General Jadwin went to Japan as a Delegate to the World Engineering Congress held in October and November, 1929. He then continued on around the world, visiting many lands that he had not had time to see during his busy career. He returned to the United States in June, 1930, in time for the Fortieth Reunion of his Class at West Point.

He was called into consultation on a number of engineering projects, and continued his membership on the Interoceanic Canal Board, which was appointed to study the matter of increasing the facilities at the Panama Canal and to bring up to date the investigations made many years ago with regard to the Nicaragua Canal. In February, 1931, he went to Panama on his way to Nicaragua to go over the ground and while in Panama, he was seized with a cerebral hemorrhage, from which he died on March 2, 1931, after an illness of only a few hours.

General Jadwin's crowning achievements were the execution of the great construction program in France during the World War and the development of the Mississippi flood-control plan. For his services in the war he received the Distinguished Service Medal, with citation as follows:

> "For exceptionally meritorious and distinguished services. As commanding officer of the 15th Engineers, he inaugurated the important project at Gievres. Later, in charge of the Division of Construction and Forestry, he brought to this important task a splendidly trained mind and exceptionally high skill. His breadth of vision and sound judgment influenced greatly the successful completion of many vast construction projects undertaken by the American Expeditionary Forces."

He was also decorated by Great Britain with the order of Companion of the Bath, and by France with that of Commander of the Legion of Honor. In 1925, he received the degree of Doctor of Engineering from Lafayette College.

In his early life, General Jadwin was of rather slight physique. His four years at West Point did wonders for him, and the care that he always took of himself enabled him to meet the physical demands of his exacting duties. He suffered during much of his life from serious defects of eyesight, which required many severe operations and special glasses. At one time he had to depend on some one to read his papers to him and to look after his office work. Many a man would have given up the fight and gone on the retired list, and thereby would have missed the opportunities and achievements of the Panama Canal work, the vast construction program in France, and the Mississippi flood-control problem.

General Jadwin's equipment as an engineer was based on exceptional native ability, utilized to a high degree. He had a mind far above the average, and he was willing to trust his mental processes and to abide by the result to which they brought him. His tenacity would not allow him to give up a subject but partly finished. He liked to give the most thorough study to any subject in hand, but he had a pronounced aversion to anything savoring of delay in execution after the decision was reached. He had a faculty for looking far into the future and for probing deeply into the springs of human action.

He was married on October 6, 1891, to Jean Laubach, of Easton, Pa. She survives him, with their two children, Charlotte, the wife of Maj. Thomas G. Hearn, U. S. A., and Lieut. Cornelius C. Jadwin, also of the Regular Army.

General Jadwin was elected a Member of the American Society of Civil Engineers on April 20, 1925.

ANDREW MARTIN JENSEN, M. Am. Soc. C. E.[1]

Died April 26, 1932

Andrew Martin Jensen, the son of Martin and Adelheid (Jorgensen) Jensen, was born on January 10, 1889, in Fresno, Calif. After graduating from the public schools of Fresno City, he entered the University of California, from which he was graduated in 1917 with the degree of Bachelor of Science in Civil Engineering.

Municipal engineering, particularly sanitary engineering, seemed to be of especial interest to Mr. Jensen, and it was to this subject that he devoted most of his energy in college. He did not complete his university work in continuity, but chose rather to avail himself of a leave of absence in the middle of his course, in order to gain some practical experience before bringing his college education to a conclusion. His brother, Christian P. Jensen, M. Am. Soc. C. E., was engaged at that time in the design and supervision of a number of sewage disposal and water-works systems in the San Joaquin Valley, and he was given the opportunity to associate himself intimately with these projects. This, together with his subsequent graduation, formed an admirable background with which he established himself immediately as a Sanitary Engineer. During his college intermission he also held a Deputyship for eighteen months in the office of the City Engineer of Fresno.

From May, 1917, to January, 1919, Mr. Jensen was associated with his brother and Mr. J. A. Ross, under the firm name of Jensen, Jensen, and Ross, Civil Engineers, engaged in irrigation reclamation, structural design of buildings, sewerage, sewage disposal, and street paving, in a number of cities in the San Joaquin Valley. In January, 1919, he assumed complete charge of the business of the co-partnership, and continued to handle a large volume of professional work, under his own name, until April, 1925.

In April, 1925, Mr. Jensen was elected to the office of Commissioner of Public Works in the City of Fresno, and in April, 1929, was re-elected to the same office. His duties in this office were very extensive, including the design and maintenance of streets, sewers, sewage disposal, street-lighting systems, fire-alarm systems, public buildings, garbage collection and disposal, and a municipal airport. The airport design was particularly unique and effective and inspired a full measure of favorable comment in the scientific press as well as in newspapers of the State.

The one achievement for which the community of Fresno will always be grateful, was Mr. Jensen's initial proposal that the municipality purchase the water-works system, which, at the time, was owned and operated by a private corporation. Before resigning from his office, he was responsible for the accumulation of a large amount of statistical data, including a complete appraisal of the system, in conjunction with the State Railroad Commission, and also for an extensive publicity and educational program, resulting, eventually, in a favorable election and subsequent purchase of the system.

---

[1] Memoir prepared by Christian P. Jensen and C. G. Gillespie, Members, Am. Soc. C. E.

Just two years before his death, he resigned from his office as Commissioner of Public Works, to engage in private engineering practice in San Francisco, Calif. At the time of his tragic death he was working on an assignment from the Clay Products Institute of California. He was examining a sewer system at El Centro, Calif., and was overcome by sewer gas while in a deep manhole. Thus was brought to an end the life of one who had always been extremely careful to protect others from the very circumstances which led to his own death. He was always solicitous for the welfare of others, before his own, and never permitted his associates to undertake any hazardous investigation unless he himself was in the front line.

Mr. Jensen was favorably known among the members of the Engineering Profession in California, and his death came as a distinct shock to them, knowing that his work was his hobby, that to it he devoted all possible energy and earnestness, and that most of his life was given to public service.

Mr. Jensen was a member of the Sigma Zi and Tau Beta Pi (honor) Fraternities, and was a Thirty-third Degree Mason.

He is survived by his widow, Lillian M. Jensen, two sons, Philip and Martin, one daughter, Mildred Ann, and a brother, Christian P. Jensen, of Fresno.

Mr. Jensen was elected a Member of the American Society of Civil Engineers, on March 5, 1928.

WILLIAM HENRY JONES, M. Am. Soc. C. E.[1]

DIED APRIL 22, 1932

William Henry Jones, the son of John and Elizabeth Jones, was born on December 1, 1859, in London, England.

His education was obtained in London, and, at the age of twenty-one, he was employed as a Rodman on a Government survey in South Australia.

In 1882, Mr. Jones returned to England and came to the United States in 1883. From 1883 to 1887, he was in the employ of the Atchison, Topeka and Santa Fé Railroad Company, first (1883 to 1885) as Bridge Foreman and from 1885 to 1887, as Inspector of Bridges during construction.

In January, 1887, he entered the employ of The Missouri Valley Bridge and Iron Works, of Leavenworth, Kans., and was still actively engaged in work for the same Company at the time of his death. He had been in the employ of the Company for forty-five years, and had served as Principal Assistant Engineer for the past thirty-seven years.

Some of the larger projects on which Mr. Jones was engaged during this time, were: The bridge over Red River, Torras, La.; the bridge over Cañon de la Mauo, Mexico; Tampico wharf, Tampico, Tamps., Mexico; St. John's River Bridge, Jacksonville, Fla.; and the Broadway and Main Street Bridges, Little Rock, Ark.

---

[1] Memoir prepared by Clarence S. Jones, M. Am. Soc. C. E.

Mr. Jones was gifted with a marked ability in original design, and many projects completed by the Company bear evidence of his good judgment and engineering skill.

He took a personal interest in assisting young engineers under his charge, and his willingness and thoroughness in imparting practical knowledge will long be remembered by those who worked under him. He was of a genial disposition, and his many friends and business associates mourn his loss.

In 1886, Mr. Jones was married to Erminie J. Strain, of Lawrence, Kans., and they had lived in Leavenworth, Kans., for the past forty-six years. He is survived by his widow and a son, Clarence S. Jones, M. Am. Soc. C. E.

Mr. Jones was elected a Member of the American Society of Civil Engineers on May 4, 1904.

ALFRED LAWRENCE KEHOE, M. Am. Soc. C. E.[1]

Died October 17, 1931

Alfred Lawrence Kehoe, the son of Alfred L. and Christiana (Welde) Kehoe, was born on July 18, 1889, in New York, N. Y., where his father had practiced architecture for many years.

Mr. Kehoe attended the public schools of New York City, and at the age of 14 entered the employ of the American Bridge Company where he worked as a Draftsman on steel design and, later, on detail shop drawings. He remained with this Company for four years, during which time he took special work in Structural Engineering at Columbia University.

In 1908, he was employed by J. J. Smith, General Contractor, as Architectural Draftsman and Assistant to the Building Superintendent. He remained with Mr. Smith until the spring of 1909.

In the fall of 1909, Mr. Kehoe entered the service of Balcom and Darrow, Consulting Engineers, New York City, where he remained until the firm dissolved partnership on January 1, 1916. During this time, he was employed first as a Draftsman and, later, as Assistant Designing Engineer, working a large part of the time on buildings for the Grand Central Terminal Improvement.

When H. G. Balcom, M. Am. Soc. C. E., took over the business of Balcom and Darrow, Mr. Kehoe was made Engineer-in-Charge of the office, which position he held until 1919, when he became a member of the firm. During these years, he was connected with many important buildings, not only in New York City, but in many parts of the United States, including the Bowery and Greenwich Savings Banks, the Pershing Square, Johns-Manville, and Liggett-Winchester Office Buildings, and the Fifth Avenue Hospital, in New York City; the Allegheny General and Children's Hospitals, in Pittsburgh, Pa.; the Tennessee War Memorial and the Peabody Demonstration School, in Nashville, Tenn.; also, a large number of college buildings for

---

[1] Memoir prepared by H. G. Balcom, M. Am. Soc. C. E.

Columbia University, Barnard College, College of the City of New York, Hunter's College, Connecticut College for Women, University of Michigan, and Wellesley College. Mr. Kehoe also had charge of many more buildings too numerous to mention.

He was one of the founders and the first Secretary of the New York Chapter of the New York State Society of Professional Engineers and Land Surveyors. He was a member of the Leewood Country Club, and, in 1931, he was President of the Hundred-for-One (100 for 1) Club. He was also a member of Kane Lodge No. 454, F. and A. M.

Alfred Kehoe was of a genial disposition and a host of friends mourn his loss, not only as a loyal and pleasing friend, but as a man of exceptional ability.

In 1915, Mr. Kehoe was married to Grace Stearn, of New York City. They lived in Washington Heights until 1926, when they removed to Scarsdale, N. Y. It was here that he died suddenly of pneumonia, on October 17, 1931.

He is survived by Mrs. Kehoe, a daughter, Grace, a brother, Edward S. Kehoe, and two sisters.

Mr. Kehoe was elected an Associate Member of the American Society of Civil Engineers on September 10, 1918, and a Member on June 16, 1924.

SENTARO KONDO, M. Am. Soc. C. E.[1]

Died January 22, 1931

Sentaro Kondo was born at Kanazawa, Japan, on April 24, 1859. He received his technical education at the Imperial University of Tokyo, Japan, and was graduated therefrom on July 10, 1883, with the degree of Bachelor of Science.

In September, 1883, following his graduation from college, Mr. Kondo entered the Government Service and was appointed Resident Engineer on the Mogami River Improvement. From 1885 until he retired in 1910 on account of ill health, he was connected with the Tokyo District, Home Department, where he served as Principal Assistant Engineer from 1885 to 1910 on the improvement of the Tonegawa River, as well as Resident Engineer on the Tone Canal. In 1887, he was also appointed Inspecting Engineer of Public Works, and as such was connected with all the public works, except railroads, in the Tokyo District.

In 1896 and 1897, Mr. Kondo gave a course of lectures at the Tokyo Imperial University, on River and Harbor Work, and in March, 1900, he was sent to Europe and the United States by the Japanese Government to study European and American methods in engineering.

In addition to his work as Director of Public Works in the Tokyo District of the Home Department, to which office he was appointed in 1906, Mr. Kondo was in charge of the Chair of Agricultural Engineering in Tokyo Imperial University from June, 1906 to March, 1922.

---

[1] Memoir prepared from information on file at the Headquarters of the Society.

In March, 1910, he was placed in charge of a land improvement project by the Department of Agriculture and Commerce, in which work he continued until March, 1925. He also served as Chief Engineer of the Toshin Water-Utilization, at Kintei, Korea, from 1920 to 1922, and from 1925 until ill-health compelled him to retire, he was again in charge of land improvement for the Department of Agriculture and Forestry.

In June, 1898, Mr. Kondo had conferred upon him the Sixth Order of the Sacred Treasure and in June, 1908, the Third Order. This decoration is given by the Emperor only to those who, for many years, have had full charge of important work under the Government. In 1912, he received the degree of Doctor of Engineering from the Department of Education.

Mr. Kondo devoted his life to the practice of hydraulics, irrigation, and drainage, in the service of the Japanese Government, his most important work having been the improvement of the Tone River

He was a member of the Engineering Society of Japan, the Civil Engineering Society of Japan, and an Associate Member of the Institution of Civil Engineers of Great Britain.

Mr. Kondo was elected a Member of the American Society of Civil Engineers on November 7, 1900.

WILLIAM HENRY LAWTON, M. Am. Soc. C. E.[1]

DIED NOVEMBER 4, 1931

William Henry Lawton, a son of William H. and Charlotte Amelia (Tilley) Lawton, was born in Newport, R. I., on April 14, 1853. After his primary education, he attended the Newport High School for a time. In 1872, he received his first training in engineering when at the age of 19 he entered the office of a local engineer, remaining there about a year.

This work, although perhaps elementary in character, must have induced in him the desire for a real education, because he determined to continue his studies through high school and college. In 1873, the City of Newport constructed a fine new High School, the gift of Mr. William Sanford Rogers. The first class to be graduated from this new school was that of 1874, and Mr. Lawton, after his one year of further study, was of the eight then graduated. In September, 1874, he entered the Massachusetts Institute of Technology as a Sophomore and continued with his class at the Institute until May, 1876, completing the second and third years of the Civil Engineering Course.

Newport was then and is now an important military and naval center. For a year Mr. Lawton was in the employ of the City of Newport; but in April, 1878, he was appointed to a position in the United States Engineer

---

[1] Memoir prepared by George T. Seabury, M. Am. Soc. C. E.

Department and sent to superintend the construction of the Block Island Breakwater. For three years he was engaged in this branch of the Government service, at Block Island, on the Providence River improvement, and on surveys, until in April, 1881, he was made Assistant United States Engineer by Gen. G. K. Warren, U. S. A., and placed in charge of the construction of jetties at the entrance to Nantucket Harbor, Massachusetts. He continued there until February, 1884, after which, until the time of his death, he practiced civil engineering in Newport, specializing in sanitary engineering and in road work.

During this interval Mr. Lawton twice held a public engineering office; from 1885 to 1889 as Street Commissioner for the City of Newport, and from 1903 to 1914 as its City Engineer. He retired from active practice in 1922.

It was in the interval between these official connections and during the writer's first summer vacation of his college course that, wanting to do some practical work, he appealed to Mr. Lawton, who promised some day to give him a job. The promise was kept and one afternoon soon afterward his chance came to hold the zero end of the tape on a small survey. At the end of the afternoon Mr. Lawton generously gave him fifty cents. He demurred but Mr. Lawton insisted, saying the rate of pay for that position was $1.00 per day; the money was his and he must take it. Mr. Lawton was just as scrupulously punctilious in all business transactions to the day of his death.

Newport at the time of Mr. Lawton's greatest activity in private practice was developing as a "summer colony" for "the Four Hundred," and their magnificent estates on the rock-bound New England Coast presented many private sewage disposal problems the solution of which fell to Mr. Lawton. Access roads and grading, too, called for his advice, design, and supervision.

He loved his work for its own sake and for the sake of those with whom it brought him in contact. Sometimes it was only a farm to be surveyed, but the work was studied as meticulously as if it were in the heart of the metropolis.

He had a sense of humor that was delicious. On one farm survey it was reported to him that a boundary was of a certain length. He told his assistants that they must have made a mistake because the records of an earlier survey, made by a lame man, showed it to be 100 ft. shorter. His party re-measured the line, reporting their figure as correct and those of the earlier survey as incorrect. Mr. Lawton sighed and said "Well, maybe he paced it and lost that hundred feet with his short leg." However, he checked it again himself to be sure.

Mr. Lawton joined the Society when the total membership was only about 1 025. His Society number, 972, and his name were engraved on the back of an old-style Society badge which he wore as a necktie pin. On February 1, 1931, he suffered a paralytic stroke from which he never wholly recovered, dying on November 4, 1931, at the age of 78; but in that interval he sent the pin to the writer with the request that he wear it as his own after he had had the new name and number engraved on it. It has been an honor to write this memoir at Mr. Lawton's own request—to tell, with enthusiasm, of a generous, kindly, humor-loving man and withal a most scrupulous and capable engineer.

Mr. Lawton was married on December 4, 1889, to Mary J. Becar who, with a son, Charles S. Lawton, a daughter, Mrs. Evelyn Hubbard, and a sister, Mrs. B. B. H. Sherman, survives him. He was a member of the Protestant Episcopal Church, and Secretary of the Seamen's Church Institute.

Mr. Lawton was elected a Member of the American Society of Civil Engineers on June 2, 1886.

GEORGE HERBERT LELAND, M. Am. Soc. C. E.[1]

Died February 11, 1931

George Herbert Leland was born in Cavendish, Vt., on May 16, 1849. He was the oldest son of Octavius A. and Adeline P. Leland (*née* Burnham), both of Lowell, Vt. His parents were direct descendants of Henry Leland, who settled in Grafton, Mass., in 1752. The boy's mother died in 1853, and for a time thereafter he was cared for by his Grandmother Leland.

In 1855, after his father had taken Martha J. Hayden as a second wife, the family moved from New England to Lambert, Wis., where they remained only a short time and then established their home on a farm a short distance west of Waukegan, Ill. In 1860, the family with goods and chattels in three "prairie schooners" went to a farm in Elgin, Minn., by way of the Overland Route, crossing the Mississippi River at Prairie La Crosse, and following the line of the present Winowa and St. Peters Railroad. Here, Mr. Leland remained for a time, taking advantage of such benefits as were offered by a pioneer country school. Meantime, the Civil War having broken out, his father had enlisted in the Union Army and was engaged in the military activities around Nashville, Tenn. His father died on his way home from the war; his stepmother had died in 1863. In November, 1865, as soon as business matters could be disposed of at Elgin, Mr. Leland went back to New England, to live with his grandfather at Athens, Vt. Here, he attended the district school and worked for his board.

In the spring of 1866, Mr. Leland entered the employ of the Lampson Goodnow Company, Machinists, at Windsor, Vt., with which Company he served a three-years' apprenticeship and then worked as a Journeyman covering a period of about fifteen years. In the autumn of 1881, he went to the Brown and Sharpe Manufacturing Company, at Providence, R. I., where he worked in the Tool Department until the following spring. Notwithstanding the fact that he was offered a responsible position with this Company, he decided, after careful consideration, to change from mechanical work to civil engineering.

---

[1] Memoir prepared by O. Perry Sarle, M. Am. Soc. C. E., from data assembled by Mr. Leland.

Early in 1882, Mr. Leland entered the office of the late J. Herbert Shedd, M. Am. Soc. C. E., as a student in Civil Engineering, and remained with him for about eight years. He then accepted a position as Engineer for the construction of a water-works plant at Troy, Ala. In 1891, he was in charge of construction of a system of sewers at Berkely, R. I. During the latter part of this year he accepted a position as Chief Assistant to the late Samuel M. Gray, M. Am. Soc. C. E., which he held for about thirty years. In this position Mr. Leland was engaged in engineering work on many important projects in the United States, Mexico, and Cuba.

Mr. Leland was a member of the New England Water Works Association, having been elected to that body in 1914, and of the Providence Engineering Society. He was a member of the First Baptist Church of Providence.

He was also a member of the New England and Rhode Island Botanical Clubs and was especially interested in botanical studies and in making collections of specimens of various sorts. His collection comprised about 4 000 specimens, including 400 ferns.

Mr. Leland was married, in 1870, to Amanda L. Harris, of Windsor, Vt. There were no children and, as his half-brother and sister had died a few years before, he was the last surviving member of his immediate family. He died in Providence on February 11, 1931.

Mr. Leland was elected a Junior of the American Society of Civil Engineers on March 2, 1887, and a Member on February 7, 1893.

MILO STUART MacDIARMID, M. Am. Soc. C. E.[1]

DIED JUNE 6, 1929

Milo Stuart MacDiarmid was born at Truxton, N. Y., on July 27, 1872. He was the son of Hugh Stuart and Lucy Louise MacDiarmid.

After graduation from Homer Academy, at Homer, N. Y., Mr. MacDiarmid entered Cornell University, from which he was graduated in 1895, with the degree of Bachelor of Science in Civil Engineering.

Nearly all Mr. MacDiarmid's engineering work was done in the service of the United States Government. This service began in 1900 as Inspector on Government projects at Chicago, Ill. He was employed by the United States Lake Survey, with headquarters at Detroit, Mich., in 1902, and continued in that service until his death, with the exception of several months when he was engaged on the survey of the Des Moines River, in Iowa.

In 1921, Mr. MacDiarmid was appointed Assistant Engineer in charge, at the headquarters of the Lake Survey, in Detroit, and, in 1926, he was made Associate Engineer. He was stricken with the illness which caused his death, on the U. S. Steamer *Margaret,* while actively engaged in deep-water soundings on Lake Superior, off the shore of Isle Royale.

---

[1] Memoir prepared by Charles Y. Dixon, M. Am. Soc. C. E.

Mr. MacDiarmid appreciated greatly the finer things of life and with him there was no compromise between right and wrong. His associates knew him as a remarkably splendid character, with a pleasing personality. Although others are carrying on his work, a void will long remain in the U. S. Lake Survey personnel who knew and respected him. His death is a distinct loss to the Engineering Profession.

He held the rank of Major in the Officers Reserve Corps, and was a member of the Presbyterian Church, the Masonic Order, Cornell University Club, and the Army and Navy Club.

He was married on May 5, 1900, to Katherine E. Cobb, who, with a son, Hugh Stuart, and a daughter, Louise, survives him.

Mr. MacDiarmid was elected an Associate Member of the American Society of Civil Engineers on September 4, 1907, and a Member on April 5, 1910.

ERNEST McCULLOUGH, M. Am. Soc. C. E.[1]

Died October 1, 1931

While newspapers were carrying complimentary reviews of his latest book, Colonel Ernest McCullough, engineer, architect, soldier, author, and journalist, died October 1, 1931, at the age of 64. His death marked the end of a versatile career, but his dynamic personality lives on in the memory of the many who prized his friendship and who respected his abilities as engineer, teacher, economist, and writer.

Throughout his life his friendships increased as his accomplishments extended to varied fields. Men admired his wealth of knowledge on many subjects gained through his intensive reading, study, and ability to retain what he read; they liked him for his kindly interest in and willingness to help young engineers plan their careers; and they acknowledged his professional ability as demonstrated on the many important projects with which he was associated.

Born on Staten Island, New York, on May 22, 1867, Ernest McCullough was the son of James and Caroline (McBlain) McCullough. After graduating from the Institute of Technology in Chicago, Ill., he went to the Pacific Coast where he received his engineering degree from the Van der Naillen School of Practical Engineering, in San Francisco, Calif. He also completed an Architectural Course at this school.

Originally, Mr. McCullough specialized in municipal work, acting as Consulting Engineer of the Merchants Association of San Francisco. There, he was Chief Engineer for the Midwinter Exposition and built the Sutro Baths. In 1898, he went to Lewiston, Idaho, where he held the office of City Engineer and was also engaged in private practice. From there, he moved to Chicago in 1903, remaining until 1917.

---

[1] Memoir prepared by B. F. Affleck, Esq., Chicago, Ill.

During his years in Chicago, Mr. McCullough made many new friendships and enjoyed a large private practice as a Reinforced Concrete Specialist. He was for a time, Associate Editor of *Engineering and Contracting* and, later, held the same position with *Railway Age Gazette* (now *Railway Age*). He also passed the State examinations for Architects and received a license to practice architecture.

He was one of the men who worked unceasingly for the passage of a Structural Engineers' License Law, and after much opposition finally succeeded in obtaining the passage of the State Law in 1916. In this campaign, he sacrificed much of his time and personal funds.

In addition to these activities, he taught night classes at the Young Mens' Christian Association College and at Lewis Institute, where he was well liked because of his ability to impart sound advice to students in a form easy to remember. His knowledge was more practical than theoretical. Students learned from him a number of "short cuts" and practical fundamentals which he had mastered while on construction and which, later, were valuable to them in their own work.

While in Chicago Mr. McCullough was employed by the City Building Department as a member of a Committee of Three to prepare regulations for concrete flat-slab design. He also served as Chief Engineer of the Municipal Engineering and Construction Company. He constructed more than 16 miles of sewers in St. Louis, Mo., and superintended the building of water purification plants for the Union Stock Yards, in Chicago. For a time he was employed as Engineer by the City of Cedar Rapids, Iowa. In 1916, he went to the Portland Cement Association, in charge of its Fireproof Construction Bureau; he left Chicago in 1917 to take a position with the Stone and Webster Corporation, in Boston, Mass.

However, the World War was raging in Europe, and Mr. McCullough was eager to do his share. Twenty-three members of the McCullough Clan in Ireland had been killed in action, and he felt that his place was on the battlefields where they had fought and fallen. In June, 1917, he was ordered to France as Acting Chief Engineer of the American Red Cross, later becoming a Student Officer in the Gas Schools of the French and British Armies. His wife, Elizabeth Townsend Seymour McCullough, died while he was in France.

Feeling that his fellow officers were making a mistake in not mastering the French language, Major McCullough mingled with the French and, after a time, was able to address French engineering groups in their own tongue. He was gassed at the Battle of Cambrai in 1917.

In 1919, he was married to Therese Claquin, at Tours, France. At that time, he was a Lieutenant-Colonel in the Chemical Warfare Service.

After the World War, his mastery of the French language made him valuable in handling damage claims in France. In August, 1919, he returned to America to become Assistant Commandant of the Lakehurst Proving Ground and Director of the Service School for Officers of the Chemical Warfare Service. In 1920, Oskaloosa College, Iowa, conferred upon him the degree of Doctor of Philosophy.

After resigning from the Army in July, 1920, Colonel McCullough was associated for a time with the Semet-Solvay Company as Structural Engineer and, later, was Associate Editor of the *American Architect,* in New York, N. Y. In 1923 and 1924, he was with the construction firm of Dwight P. Robinson and Company, Incorporated, in New York City, leaving this association to become Chief Structural Engineer for Vickers and International Combustion, Limited, London, England. During his connection with this organization in 1925, Colonel McCullough was awarded a medal for a paper presented to the British Institute of Structural Engineers. The paper dealt with American structural engineering practices, in which field he was an acknowledged authority.

Afterward, he became Editor-in-Chief of *Building Age* (now *American Builder and Building Age*), leaving, in 1928, to engage in writing, in addition to his engineering work. Two of his best-known books are "Practical Structural Design" and "Engineering as a Vocation." His last book, "How to Spend Your Money," published only a short time before his death, is described by reviewers as being full of practical advice on investments. He also wrote articles for magazines, being a frequent contributor to *Forbes* and other financial publications.

For twenty years, Colonel McCullough made a study of economics, with particular reference to the business cycle and possible means of eliminating the peaks and depressions. As a result of this research, he wrote during the last ten years a number of articles advocating Professor Irving Fisher's theory of currency control as a means of stabilizing business conditions.

At the time of his death, Colonel McCullough was making a study of the engineering aspect of package freight handling in connection with terminal warehousing. The result of these studies was to be embodied in a book dealing with terminal freight handling in all its aspects. His ability to write authoritatively and interestingly on many subjects made his books and articles widely read.

Colonel McCullough was a Member of the Société des Ingénieurs Civils de France and the Institute of Structural Engineers (Great Britain).

Surviving him are his widow and three children—Captain George Seymour McCullough, 16th Infantry, U. S. Army, Fort Jay, N. Y.; James David McCullough, of Staten Island; and Mrs. Paul C. Galleher, of Los Angeles, Calif.

Colonel McCullough was elected a Member of the American Society of Civil Engineers on May 31, 1910.

HORACE MILLER MARSHALL, M. Am. Soc. C. E.[1]

Died October 3, 1930

Horace Miller Marshall, the son of Thomas Alexander and Letitia (Miller) Marshall, was born in Vicksburg, Miss., on August 18, 1854.

---

[1] Memoir prepared by Charles M. Kerr, Assoc. M. Am. Soc. C. E.

His early education was obtained under private tutors, and at the age of fourteen he entered Lyons Academy, at Vicksburg. He then attended Bellevue High School, at Lynchburg, Va., later enrolling in the University of Virginia, from which he was graduated in June, 1877, with the degree of Civil Engineer.

Returning to Vicksburg after his graduation, Mr. Marshall entered into the private practice of his profession, his first engagement being a survey of the harbor and water-front. From 1879 to 1883, he managed his father's plantation, "Aubrey," and in the early part of the latter year entered the employ of the Louisville, New Orleans, and Texas Railroad Company (subsequently, the Yazoo and Mississippi Valley Railroad Company), in charge of location, and, later, construction, south of Clarksdale, Miss. In the summer of 1884, Mr. Marshall became associated with the United States Engineer Office at Vicksburg. He returned to private practice in the spring of 1885, and was engaged in research and levee work in Warren, Coahoma, and Tunica Counties, Mississippi. In the summer of 1887 he had charge of railroad work in Arkansas, with the Memphis, Arkansas, and Texas Railroad Company, between Memphis, Tenn., and Pine Bluff, and from Marianna to Clarendon. In the fall of that year he re-entered the employ of the United States Engineer Office at Vicksburg, where he remained until his retirement on August 18, 1924.

During this period, he was Assistant Engineer in charge of all survey work on the Red and Ouachita Rivers in Louisiana, and on the Yazoo and Big Sun Flower Rivers in Mississippi. During the term of his active Government service, Mr. Marshall had charge of the design, as well as the general supervision, of many important public improvements, principal among which was the work of diverting the waters of the Yazoo River into Lake Centennial, which restored the Harbor of Vicksburg; the plan for the improvement of Red River; the installation of the locks and dams on the Ouachita River; and the plans for a system of locks and dams on the Big Sun Flower River. To Mr. Marshall is credited the first successful attempt at tying the ends of crevasses. He did this first at the Grand Lake Crevasse in Arkansas, in 1888; and, later, in 1890, at the Duncansby Crevasse, in Mississippi, he prevented the natural widening of the break in the levee line by his personal efforts.

After his retirement in 1924 from the Government service, he resumed the private practice of his profession, in the capacity of Consulting Engineer. Mr. Marshall's efforts in the planning of the diversion of the Yazoo River into Lake Centennial, and in the subsequent successful restoration of Vicksburg Harbor, brought him widespread recognition in engineering circles, and he was accredited with the success of this scheme.

He was an acknowledged leader in his profession, and was considered an authority upon the subject of his special life work—flood control and the improvement of inland waterways. He conceived and developed a general plan for the establishment of the Industrial Canal and Inner Harbor at New Orleans, La., many years before a similar scheme was adopted and put into operation. He also planned for the development of Red River along ambitious lines, but lack of Government appropriations and funds prevented a realization of his well-conceived and thoroughly practical ideas.

Mr. Marshall was endowed by inheritance with a refinement of sentiment and manner, and was known for his devotion and loyalty to his friends and associates. He was possessed of a keen and analytical mind, and was well versed in the higher branches of mathematics. He was a deep and studious reader and, outside his books, his chief means of recreation lay in his flower garden, in which he spent his hours of leisure.

During 1895 and 1903, he served as Alderman, and, from 1903 to 1905, as Mayor, of the Town of Speeds, Miss. During the Spanish-American War, he served as a Colonel on the Staff of the Governor of Mississippi, and was appointed Chief State Engineer, and had charge of the protection of the mouth of the Mississippi River by the laying of bombs to prevent a possible invasion by the enemy fleet. Mr. Marshall was a member of Theta Delta Chi Fraternity, and was admitted into the Masonic Order in 1892.

On January 15, 1880, he was married to Elizabeth Taylor Henry, of Vicksburg. He is survived by Mrs. Marshall, and five daughters—Mrs. Kingsland Spencer, of Tarrytown, N. Y.; Mrs. Frederick Gray Hudson and Mrs. Harry Russell, of Monroe, La.; Miss Letitia Marshall, of Vicksburg, and Mrs. Henry Charles Yaeger, of Denver, Colo.

Mr. Marshall was elected a Member of the American Society of Civil Engineers on December 3, 1890.

MONTGOMERY MEIGS, M. Am. Soc. C. E.[1]

DIED DECEMBER 9, 1931

Montgomery Meigs, for forty years always called "The Major," was born at Rouses Point, N. Y., on February 28, 1847, the son of General Montgomery Meigs, Quartermaster of the Union Army during the War of the Rebellion, and Louisa (Rodgers) Meigs. Mrs. Meigs was the daughter of Commodore John Rodgers, of the United States Navy, and Commander of the famous old frigate, *Constitution*. After a distinguished career in the war, General Meigs was intensively engaged with public work in the National Capital, and, among other things, built the Washington Aqueduct.

Montgomery Meigs' early education was secured in private schools in Washington and Philadelphia, Pa., and he matriculated at Harvard University where he studied engineering for two years. After being graduated from Harvard, he studied in the Polytechnical School at Stuttgart, Germany.

Upon his return to the United States, he accepted a position with the Northern Pacific Railroad Company, then engaged in pioneer work from Lake Superior to Puget Sound. He located and built early sections of track between Jamestown, N. Dak., and Bismarck, and laid out the first squares of what is now the City of Bismarck, S. Dak. During his two years with the

---

[1] Memoir prepared by Hugh L. Cooper, M. Am. Soc. C. E.

Northern Pacific Railroad Company, he was with two surveying expeditions up the Yellowstone River and into the Little Big Horn country, where Custer's command was lost.

The panic of 1873 brought about the disbandment of the engineering corps of the railways, and Major Meigs then went to Rock Island, Ill., where he joined an expedition to the West and Southwest. He afterward returned to Washington, D. C., where he was located for some time in the Coast Survey Office of the Bureau of Weights and Standards.

He was next appointed by the Secretary of War as United States Civil Engineer, and was stationed at Rock Island. The position of United States Civil Engineer was created by Act of Congress and Major Meigs was one of four appointed under the provisions of this Act.

In 1876, he was married to Grace Lynde, of Rock Island, whose death occurred many years ago. There were six daughters born to this union, all surviving but one, Dr. Grace (Meigs) Crowder, whose death occurred about 1926. The daughters surviving are: Mrs. Louisa (Meigs) Green, of Winchester, Va.; Mrs. Mary (Meigs) Atwater, of Helena, Mont.; Mrs. Alice (Meigs) Orr, of St. Charles, Ill.; Mrs. Frances (Meigs) Fales, of Bryn Mawr, Pa.; and Miss Cornelia Meigs, of Keokuk, Iowa. Ten grandchilren of Major Meigs were living at the time of his death.

Major Meigs went to Keokuk, Iowa, on January 1, 1882, from Rock Island, and was given charge of that section of the Mississippi River from that date until he retired on September 20, 1926, thus completing a continuous service of forty-four years. He had supervision over all the Mississippi River work and its navigation facilities between Burlington, Iowa, and Hannibal, Mo. In addition to his regular duties in charge of this section of the river, he was given general supervision of the interests of the Federal Government during the time of the construction of the Mississippi River Power Company's power plant and its lock and dry dock at the foot of the Des Moines Rapids. This service was of great interest to Major Meigs, and his judgment on all matters coming under his review was of great value, not only to the Government, but to the engineers of the Power Company. His loyalty to the river interests and to the responsibilities imposed upon him by the Government was always of first importance to him, and his constant attention to every detail of the design and construction was a distinct contribution to the successes which have attended the operation of this entire installation.

Major Meigs was especially interested in the upper gate for this lock, built to take a submerged position when boats were entering from the upper pool. This submerged gate was operated by compressed air, and Major Meigs' interest in the working out of its details constituted a distinct engineering service.

Major Meigs' entire life was distinguished by devotion to every class of duty that is found in the ideal citizen. He was frequently confronted with offers of promotion, but they were always declined because of his devotion to his six daughters, and his belief that they could be given better foundations for their life work if they were freed from the setbacks that are always incident to moving the home from place to place. He took great pride in the achievements of his daughters in the various fields of endeavor in which they were engaged.

His retirement on September 20, 1926, came at a time when he was 79 years of age. This retirement was a distinct recognition of his splendid service to his Government, and to the unusual mental and physical capacity which had been in such full evidence during his extended public service.

Many interests occupied Major Meigs during the years after his retirement from service. He was a most delightful conversationalist and one of the best read and best informed men in his vicinity. He read widely, and his interest in books is shown in the unusually fine library which he possessed. With the late Howard Elliot, Affiliate, Am. Soc. C. E., Major Meigs organized the Keokuk Book Club forty-nine years ago, and it was one of his characteristics never to abandon an effort after he had once started it.

In his retirement he was greatly interested in bird life. He helped to band specimens of birds, and was identified with this work in other ways. Major Meigs was a photographer of considerable skill, and used his camera to make records of many happenings along the Mississippi River, both in an official and an unofficial capacity. He was an early devoteé of golf, and a member of the old Keokuk Bicycle Club.

In his religious life, Major Meigs attended St. John's Protestant Episcopal Church, of Keokuk. He was absolutely devoted to his family and his home life was ideal. He found a deep pleasure in what his numerous friends were doing, and they will always revere the memory of one who had a fine understanding of scientific principles and prime citizenship, and whose life made the world better.

Major Meigs was elected a Member of the American Society of Civil Engineers on March 5, 1879.

JOSEPH DAVIS METCALFE, M. Am. Soc. C. E.[1]

Died February 2, 1931

Joseph Davis Metcalfe was born on January 21, 1886, at Georgetown, Tex., the son of J. A. Metcalfe. In 1906, he was graduated from the Agricultural and Mechanical College of Texas at which time he received the degree of Bachelor of Science in Civil Engineering.

In September, 1906, Mr. Metcalfe accepted a position with the Great Southern Lumber Company and the New Orleans Great Northern Railway Company as Masonry Inspector. He was also Instrumentman in charge of field work, and, later, in charge of detail work in the office of the Construction Engineer on the erection of saw-mill plant and railway shops at Bogalusa, La. He was thus employed until December, 1907.

---

[1] Memoir prepared by W. D. Dockery and G. R. Burtner, Assoc. Members, Am. Soc. C. E.

For the next three years, he was associated with the Altus, Roswell and El Paso Railway Company, and the Wichita Falls and North Western Railway Company, as Instrumentman and Assistant Engineer on surveys and in charge of construction. Mr. Metcalfe was a very capable engineer, and received a wide range of experience during the next six years. His dependability made him most acceptable as one to have charge of construction work.

In March, 1912, he was Instrumentman for the Quanah, Seymour, Dublin, and Rockport Railway Company. From April, 1912, to December, 1913, and from July to October, 1914, he was with the Houston and Texas Central Railway Company, as Instrumentman and Assistant Engineer in actual charge of construction, including roadbed, yards, bridges, and track. From January to July, 1914, he was Engineer in charge of construction on the Brazos River protection levee. In October, 1914, Mr. Metcalfe undertook a greater responsibility by accepting a position as Division Engineer in charge of highway construction in McLennan County, Texas. He remained there until July, 1915, when he became Assistant Highway Engineer in Bell County, Texas, for one year; during this time, he was also engaged in the preparation of plans.

From August, 1916, to April, 1917, Mr. Metcalfe increased his experience by doing valuation work with the Gulf, Colorado, and Santa Fé Railway Company. From May to July, 1917, during the planning of the road system, he was Highway Engineer on Road District No. 10 in Navarro County, Texas; and from August to November, 1917, he was Assistant Engineer and Superintendent on the construction of Camp MacArthur and Rich Field, at Waco, Tex. During the following year he filled the position of Assistant County Engineer in Dallas County, Texas, and prepared plans on highway projects.

In March, 1918, Mr. Metcalfe became a member of the firm of Isbell and Metcalfe, Civil Engineers, at Wichita Falls, Tex. The work of this firm included the location of pipe lines, the supervision of construction, refinery layouts, city and rural subdivisions, paving, the location and construction of roads and bridges, and surveys. The firm was in business about two years when in December, 1921, Mr. Metcalfe accepted a position as County Engineer in Frio County, Texas, with responsibility for the design and construction of the highway system. From 1923 to 1925, he served as Resident Engineer in the Texas Highway Department on highway construction. From 1925 to 1929, he was Consulting Engineer in Wichita Falls, and from March, 1929, until the time of his death, Mr. Metcalfe was Division Engineer in the Texas Highway Department, with headquarters at Paris, Tex.

As life is measured to-day, Mr. Metcalfe was a comparatively young man; in fact, his span was twenty-five years short of the three-score and ten allotted to men; but measured by events and achievements he had lived a life of much greater length. This untimely end cut short a career which promised great success in the engineering field. He had a high sense of responsibility and devotion to duty. He was energetic, resourceful, and all work which was entrusted to him, was fulfilled, with painstaking care.

In March, 1914, he was married to Mary Hudson, of Pearsall, Tex., and he is survived by his widow and two children, Joseph Davis and Robert Pryse Metcalfe.

Mr. Metcalfe was elected an Associate Member of the American Society of Civil Engineers on April 2, 1913, and a Member on October 22, 1924.

EUSEBIUS JOSEPH MOLERA, M. Am. Soc. C. E.[1]

Died January 14, 1932

Eusebius Joseph Molera was born at Vich, Spain, on November 14, 1846. He received his technical education at the Royal Academy of Engineers at Madrid, from which he was graduated in 1867.

Two years later Mr. Molera came to America in the employ of the Spanish Government, collecting data relating to the manufacture of war materials. As early as 1870 he found employment with the United States Corps of Engineers on harbor work at San Francisco, Calif., his name being connected with the surveys of Blossom Rock preceding its removal as an obstruction to the navigation of San Francisco Bay. Thereafter, until 1876, he was Assistant Lighthouse Engineer of the 12th District, with headquarters at San Francisco.

Mr. Molera then established himself permanently in private practice as a Consultant Civil Engineer at San Francisco, making topographic surveys, planning irrigation works, etc. He was called to Mexico in 1881 by President Gonzales to outline a project for the drainage of the Valley of Mexico. A few years later, he was employed by a syndicate of capitalists as Consultant on the completion of the Tehuantepec Railroad. This work included studies for harbor terminals on both the Atlantic and Pacific Oceans. His professional practice covered not only a wide range in engineering, but extended, too, into the architectural field.

Mr. Molera was a student of early Mexican history and from time to time gave delightful accounts of the results of his studies to his favorite technical organization—the Technical Society of the Pacific Coast. He took great interest, too, in the advancement of science, as evidenced by his activities in the California Academy of Sciences of which he was long a member and which he had served as President from 1903 to 1909.

Mr. Molera was a polished gentleman, courteous to all and pleasant to meet, a sincere and dependable friend, an engineer of recognized standing, an esteemed citizen.

He was married on April 28, 1875, to Amelia Cooper, of Monterey, Calif., who died on August 19, 1918. Of his two children, Andrew J. and Frances M., the former passed away a few months before the father's death.

Mr. Molera was elected a Member of the American Society of Civil Engineers on October 5, 1904.

---

[1] Memoir prepared by C. E. Grunsky, Past-President, Am. Soc. C. E., and D. C Henny, M. Am. Soc. C. E.

RICHARD MONTFORT, M. Am. Soc. C. E.[1]

DIED FEBRUARY 7, 1931

Richard Montfort was born in County Carlow, Ireland, on March 4, 1854. He was the son of Henry Montfort, M. D., who was a nephew of the Right Hon. Abraham Brewster, Lord Chancellor of Ireland, in 1868, and of Elizabeth (Colles) Montfort, who was a niece of Dr. Abraham Colles, of Dublin, Ireland.

Mr. Montfort was educated in Kingstown School, County Dublin, and at the Royal College of Science, Dublin, in which he held a scholarship. He was graduated in Civil Engineering in 1876 and sailed for the United States in the same year.

His first professional engagement was with the Louisville Bridge and Iron Company, of Louisville, Ky., as Draftsman, Inspector, and Assistant Engineer until 1880, at which time he entered the service of the Louisville and Nashville Railroad Company as Bridge Engineer. He was employed in this capacity until 1883, when he became Resident Engineer of the System in charge of roadway, bridges, and buildings. In 1887, his title was changed to Chief Engineer, with increased duties.

On January 1, 1905, Mr. Montfort resigned his position as Chief Engineer of the Louisville and Nashville Railroad Company, on account of ill health, and the position of Consulting Engineer of the same Company was created for him, which position he held until his death.

Mr. Montfort was a Charter Member of the American Railway Engineering Association and served for many years on its Rail Committee. He was also a Charter Member of the Engineers and Architects Club of Louisville, and a member of the Pendennis Club of that City.

He was married to Henrietta Barret, of Louisville, who predeceased him many years. He left one son, Mr. Barret Montfort, who is Vice-President of the Chemical Bank and Trust Company of New York City.

Mr. Montfort was elected a Member of the American Society of Civil Engineers on June 6, 1888. He served as a Director of the Society from 1914 to 1916, and as Vice-President in 1916.

STEPHEN HENLEY NOYES, M. Am. Soc. C. E.[2]

DIED JANUARY 21, 1932

Stephen Henley Noyes was born on November 26, 1881, at Newport, R. I He was the son of Lieut. Boutelle Noyes, U. S. N., and Charlotte B. (Luce) Noyes. His grandfather was Rear Admiral Stephen B. Luce, U. S. N., Founder of the Naval War College and the Apprentice System of the United

---

[1] Memoir prepared by W. H. Courtenay, M. Am. Soc. C. E.

[2] Memoir prepared by Robert Farnham, M. Am. Soc. C. E.

States Navy. His great-grandfather was Commodore John Dandridge Henley, U. S. N. His paternal great-grandfather was the Hon. Timothy Boutelle, who was one of the organizers of the first railroad in Maine that, later, became the Maine Central Railroad. On both his father's and his mother's side, there were nine generations in America.

Mr. Noyes first attended school at the Chateau de Lancy, Geneva, Switzerland, then, later, he was for four years at St. Mark's School, Southboro, Mass. He was graduated from Harvard University with the degree of Bachelor of Arts in 1903, and that of Bachelor of Science "Cum laude" in 1905. While at Harvard, he was a member of the Zeta Psi, The Dickie, Institute of 1770, and the Hasty Pudding Club; he was also Editor-in-Chief of the *Harvard Engineering Journal.* He played on and captained his class football team in 1902, which won the Class Championship, and, later, played quarter-back on the University team. In 1904 and 1905, Mr. Noyes was a member of Battery A of the Massachusetts Light Artillery. During 1905, he traveled in the East and shot big game in India.

After his graduation from college, he was in the employ of L. J. Johnson, M. Am. Soc. C. E., engaged on making tests of reinforced concrete beams. He then went as a Draftsman with the Underwriters Engineering and Construction Company, of New York, N. Y., being employed on the design of reinforced concrete buildings. From October, 1906, to July, 1907, he was employed as a Civil Engineer by the Kittle Construction Company, of San Francisco, Calif., on the design and methods of constructing reinforced concrete mill buildings.

From September, 1907, to October, 1908, Mr. Noyes had experience with the American Bridge Company, at its Long Island City, N. Y., plant, detailing and checking shop drawings for structural steel buildings. In 1908, he was a member of the crew of the old Cup Defender, *Mayflower,* wrecked in a hurricane in the West Indies and abandoned at sea.

Mr. Noyes was with the Pennsylvania Steel Company from 1908 to 1913 detailing and checking shop drawings for steel bridges; he then served as Assistant to the Chief of Drafting-Room on methods of bridge erection, and, later, was in responsible charge of designing falsework and travelers. He was afterward placed in the field, in responsible charge of engineering, in connection with the erection of three large bascule bridges, and made a comprehensive study and estimates of costs of bridge erection of all kinds.

In 1913, he made an expedition into the little known interior of the Kamchatka Peninsula, in Siberia. In December, 1913, he entered the service of the Pennsylvania Railroad Company.

In 1916, believing that the entry of the United States into the World War was inevitable, Mr. Noyes took lessons in aviation, and was the first man to be graduated from the Philadelphia School of Aviation, at Essington, Pa. He was named a non-commissioned officer in the Air Service Reserve before the United States entered the war. On the declaration of war by the United States, he was sent to Kelly Field, Texas, and left for France in May, 1917, as First Lieutenant Flight Commander of the 1st Aero Squadron. He served, in turn, as Commanding Officer, 12th Aero Squadron, Commanding

Officer, 5th Corps Observation Group, and Commanding Officer, Corps Observation Group, 1st Army. He received the following promotions: Sergeant, February 5, 1917, Air Service Reserve Corps; First Lieutenant, May 10, 1917, Air Service Reserve Corps; Captain, August 1, 1918, Air Service; and Major, April 23, 1919, Air Service. He was honorably discharged on May 27, 1919. He took part in the following engagements: Marne-Aisne, St. Mihiel, and Argonne-Meuse.

In July, 1918, Captain Noyes was awarded the Croix de Guerre, with the following citation:

> "Pilote de premier ordre, calme et brave, modele de devoir pour son escadrille. Le 6 juillet 1918, attaque une premiere fois par une patrouille ennemie, la dispersa par sa manoeuvre hardie et permit a son observateur de prendre les photographies desirees. Attaque une deuxieme fois, a abattu un de ses adversaires au cours d'un severe combat; a termine son vol par une reconnaissance a 500 metres d'altitude dans les lignes allemandes."

In October, 1918, he was given the Distinguished Service Cross:

> "For extraordinary heroism in action near Chatel Chehery, France, October 16, 1918. Capt. Noyes volunteered under the most adverse weather conditions to stake the advance lines of the 82nd Division. Disregarding the fact that darkness would set in before he and his observer could complete their mission, and at the extremely low altitude of 150 feet, Capt. Noyes proceeded, amid heavy aircraft and ground machine-gun fire, until the necessary information was secured. On the return, due to darkness, he was forced to land on a shell-torn field, and proceeded on foot to Headquarters with valuable information."

After being discharged from the Service, Mr. Noyes again entered the employ of the Pennsylvania Railroad Company, where he remained until 1920. During his service with this Company, he made designs of all classes of railroad bridges, and had charge of the inspection and repair of existing highway bridges throughout the System.

From July, 1920, to February, 1927, he was head of the Bridge Department of the City of Philadelphia, in which position he had charge of the design and erection of all bridges built by the City. The outstanding bridges which he designed and erected while in the municipal employ are the South Street Bridge and the University Avenue Bridge over the Schuylkill River.

From 1927 to the day of his death, Mr. Noyes was Assistant to the Chief Engineer of the Philadelphia Improvements of the Pennsylvania Railroad, and, in this capacity, had complete charge of the design of all structural steel and reinforced concrete, as well as all other types of construction.

He was always a tireless worker, and was noted for his accuracy and sound judgment. He was recognized by his associates as an authority in his particular line of work, and his unfailing and absolute honesty of purpose was recognized and admired by all his co-workers. He had a wonderful sense of humor, was a delightful companion, and could play just as hard as he could work.

His principal recreation was golf, at which he excelled, and, during the last years of his life, he could generally be found on the golf links if he was not in the office.

Mr. Noyes was a member of the following clubs: Philadelphia Club, Philadelphia Cricket Club, Racquet and Tennis Club, Philadelphia; Metropolitan Club, of Washington, D. C.; University Club, and Harvard Club, of New York, N. Y.; the Military Order of the Loyal Legion; and the Mayflower Society.

His sudden death was a great shock to a host of friends in all parts of the country.

Mr. Noyes was elected a Junior of the American Society of Civil Engineers on October 1, 1907, an Associate Member on February 6, 1912, and a Member on January 20, 1922.

FREDERICK SYLVESTER ODELL, M. Am. Soc. C. E.[1]

Died October 20, 1931

Frederick Sylvester Odell, the son of Harry and Elizabeth Ward (Tompkins) Odell, was born at Mt. Kisco, N. Y., on June 8, 1850. He was educated at private schools and at Cooper Union, New York, N. Y.

Mr. Odell's first entry into the field of engineering in 1870 was as Assistant Engineer under Thomas C. Cornell, Civil Engineer, of Yonkers, N. Y., engaged in highway and dock construction and in general practice. In 1871, he was appointed Assistant Engineer in the Department of Public Parks, New York City. He remained in the employ of the City of New York until 1873, when he was placed in charge of highway and park development in the City of Cohoes, N. Y., under the direction of Robert Weir, Civil Engineer. In 1874, he returned to Yonkers and was in responsible charge of the preliminary surveys for a water supply for that city.

In 1875 Mr. Odell was re-employed by the New York City Park Department on the construction of Riverside Drive, remaining on this work until 1879, when he became Resident Engineer on the construction of the southerly end of the Putnam Division of the New York Central Railroad, completing this work. In 1880, he was placed in charge of the construction of sewers at Memphis, Tenn., under George E. Waring, Consulting Engineer. From 1881 to 1890, he was associated with the late J. James R. Croes, Past-President, Am. Soc. C. E., as Principal Assistant Engineer on surveys for the Suburban Rapid Transit Railways, and the Princeton, N. J., Water-Works, acting also as Engineer in Charge of Design and Construction of the sewerage systems for Lawrenceville, Seabright, and East Orange, N. J.

In 1890, Mr. Odell became associated with the office of the late Charles B. Brush, M. Am. Soc. C. E., and was actively engaged in the construction of water-works at New Rochelle, N. Y., and in North Hudson County, New Jersey. Also, during this period, he was employed on preliminary work for the proposed Hudson River Bridge. In 1892, he was appointed Commissioner of Public Works for the City of Mount Vernon, N. Y., and was instrumental in the design and construction of the many municipal improvements then being undertaken in that city. He remained in this position until 1898 when he resigned to become associated with the Engineer in charge of "Montreat," a large real estate development in the mountains of North Carolina. Completing this work, Mr. Odell returned north and entered general practice as a professional engineer, with an office at Port Chester, N. Y., where he remained actively engaged until 1916. During this period he designed and built the sewerage system and disposal works for that village.

---

[1] Memoir prepared by James R. Rundell, Esq., Port Chester, N. Y.

In 1916, Mr. Odell organized the F. S. Odell Engineering Corporation, and as its President specialized in large real estate developments, landscape engineering, and general surveying practice, being also one of several engineers employed in the real estate surveys and land acquisition for the Westchester County Park Commission.

In 1927, he retired to private life, spending his last remaining years at his home in Mount Vernon, and his country home at Wahackme Woodland, New Canaan, Conn. Able of mind and active of body until only a few months before his death, he suffered a general breakdown which led to a complication of diseases causing his death in the Mount Vernon Hospital, on October 20, 1931, at the age of 81 years. He was buried in Oakwood Cemetery, Mt. Kisco, N. Y.

He was married in June, 1888, to Carrie McLane Davis, of Mount Vernon, who died on November 21, 1914. He was married a second time to Mary Lyman, also of Mount Vernon. He is survived by a niece, Mrs. Grace Odell Burt, of Brooklyn, N. Y.

A deep student and of brilliant mind, Mr. Odell's retiring nature and modesty did not allow the world to know the fineness of the man. A gentleman of the old school, genial and friendly to his intimates, brave in adversity, the soul of honesty, and a most thorough and capable engineer, the profession and his associates will deeply feel his loss.

Mr. Odell was elected a Member of the American Society of Civil Engineers on March 5, 1884. He was also an Honorary Member of the Westchester Society of Civil Engineers.

ARTHUR ONDERDONK, M. Am. Soc. C. E.[1]

Died January 22, 1932

Arthur Onderdonk, the son of Andrew Onderdonk and Sarah (Hillman) Onderdonk, was born at Yale, B. C., Canada, on January 29, 1881. His father was a noted engineer and contractor.

After attending McGill University, in Montreal, Que., Canada, and Columbia University, in New York, N. Y., each for one year, Mr. Onderdonk started his engineering career in 1900 under the late Ira A. Shaler, M. Am. Soc., C. E., Contractor. His work consisted principally in measuring materials and cross-sectioning in the tunnels of the New York City Rapid Transit Commission.

---

[1] Memoir prepared by John G. Claybourn, M. Am. Soc. C. E., and L. B. Moore, Assoc. M. Am. Soc. C. E.

From 1901 to 1903, as Assistant Engineer for his father, he was engaged on contract work and estimating. From 1903 to 1907 he was Assistant to his father's Chief Engineer on subaqueous tunnel works, mainly on the East River Tunnel and the Rapid Transit Loop, at Battery Park, New York City.

During parts of 1907 and 1908, Mr. Onderdonk was employed in different capacities on various projects as follows: Timber Superintendent, Philadelphia, Pa., Rapid Transit; Foreman and, later, Levelman, Panama Canal; Contractor's Assistant Engineer on railways in Costa Rica; and Civil Engineer on surveys and design of hydro-electric plants for the H. T. Purdy Engineering Company, at San José, Costa Rica.

For the next six years (1908–1914), Mr. Onderdonk was Engineer in charge of construction for the Abangarez Gold Fields of Costa Rica. He supervised the design and construction of roads, buildings, narrow-gauge railroads, aerial tramway, and a modern 60-stamp mill, with accessory and auxiliary plants.

During 1914 and 1915, he was engaged in the private practice of surveying for land improvements at Oyster Bay, N. Y.

From July, 1915, until January, 1916, he was Assistant Engineer for the Eden Mining Company, in Nicaragua, on the survey for and design of a new installation. From January to September, 1916, he was Assistant Engineer on surveys and location for the Tela Railroad, in Honduras. For a few months in 1916 and 1917, he assisted in installing plant on the East River Tunnel, New York City, for the Contractor, Patrick McGovern.

In March, 1917, Mr. Onderdonk returned to the Abangarez Gold Fields of Costa Rica as Superintendent and Assistant Manager, and, later, as Acting Manager. His work included the design and construction of structures for the San Rafael Mine. He remained in this position until November, 1919.

From December, 1919, to January, 1921, he was Chief Engineer and Manager of the Piermont Mines Company, in Nevada. His duties included the supervision of new installation and surveys, as well as examinations of various claims, properties, and structures.

From January, 1921, to April, 1924, he was Consulting and Chief Engineer for Mr. J. N. Popham in connection with the latter's development of manganese mines in Panama.

For a few months in 1924 Mr. Onderdonk assisted the Contractor on the Bear Mountain Bridge over the Hudson River. From December, 1924, to April, 1926, he was Estimator on the Canal Zone for the Constructing Quartermaster, U. S. Army. Since April, 1926, he had been engaged in structural design work for the Panama Canal. During this period he had also served as Engineer in charge of the Barraza Fill Development, in Panama City, and had done some work for the Panama Corporation, a gold mining company with extensive properties in the Republic of Panama.

During his long and varied career as an engineer over a period of thirty-one years, Arthur Onderdonk made an unusually large number of friends among whom his loss is deeply felt. He was a member of the Century Club, of Panama City.

He was married in 1911 to Gertrude Bruce, of Mount Vernon, N. Y., and is survived by his widow and two sons, Andrew and Arthur Bruce.

Mr. Onderdonk was elected an Associate Member of the American Society of Civil Engineers on January 6, 1915, and a Member on March 16, 1925.

WILLIAM COLLINS PHELPS, M. Am. Soc. C. E.[1]

DIED JUNE 19, 1931

William Collins Phelps was born on December 19, 1867, at Claremont, N. H. He was a descendant of Edward Phelps who came to America from Bolton, England, in 1634, and settled in Andover, Mass., and, on his mother's side, from the Denio family, connected with the early history of Deerfield, Mass., and the Allens, prominent in the history of Vermont in Revolutionary times.

Mr. Phelps attended Stevens High School, in Claremont, and was graduated from Dartmouth College in 1893, with the degree of Bachelor of Science, and from the Thayer School of Civil Engineering in 1895, with the degree of Civil Engineer.

During his vacation periods, while still attending college, Mr. Phelps worked as a Draftsman for the Boston Bridge Works, and as a Transitman for the City Engineer of Cambridge, Mass. Following his graduation, he went with the United States Engineer Corps on surveys in Northern Virginia. From September, 1895, to August, 1897, he was a Structural Steel Draftsman for C. L. Strobel, M. Am. Soc. C. E., in Chicago, Ill., and for the firms of Purdy and Henderson, and Post and McCord, in New York, N. Y.

From 1897 to 1923, Mr. Phelps was engaged in work on street railways, elevated lines, and subway lines in and around New York City. He started as a Draftsman with the Metropolitan Street Railway Company and one year later, 1898, became Assistant Engineer for the Edison Electric Illuminating Company of New York, preparing plans for central stations. In 1899, he was engaged by the Manhattan Railway Company as Assistant Engineer on the preparation of plans for the electrification of the elevated railroad lines. This work included the structural design of the main power station at 74th Street and the East River, and of seven sub-power station buildings.

In 1901, he became Assistant Engineer in the Mechanical Engineer's Department of the Rapid Transit Subway Construction Company and the Interborough Rapid Transit Company. In this capacity he was in charge of the structural design of the power station at 59th Street and Eleventh Avenue, nine sub-power stations, and repair shops, car sheds, and auxiliary buildings, at the Lenox Avenue and West Farms Terminals. He served with the Interborough Rapid Transit Company in the development, estimates, and construction of new subway lines until 1918. From 1918 to 1923, he was engaged on similar work with several independent lines in New Jersey. In 1923, he was with Post and McCord, in New York, on the Edison Power Station at 14th Street.

---

[1] Memoir prepared by A. J. Wilcox, M. Am. Soc. C. E.

From July, 1927, until his death, Mr. Phelps was employed by H. G. Balcom, M. Am. Soc. C. E., Consulting Engineer, New York City, as a Structural Engineer. In this position he was engaged on the design of various buildings and projects, which included work on some of the highest structures in New York City, and, notably, the framing for the elaborate stone work on the Department of Commerce and Post Office Department Buildings in Washington, D. C.

Mr. Phelps' natural inclination for painstaking attention to detail and thoroughness of analysis, made him especially suited for the most intricate design. He showed a conscientiousness and completeness in his work that was a satisfaction to all who had any occasion to deal with him or his efforts.

He was a great lover of Nature and of the out-of-doors. Camping was a favorite recreation with him. One of his camping trips had taken him to British Columbia a number of years ago.

Mr. Phelps was a member of the Thayer Society of Engineers of Dartmouth College, a life member of Prince of Orange Lodge, and a member of Constitution Chapter, Royal Arch Masons, New York City.

He died in Brooklyn, N. Y., after an illness of only a few weeks. The interment was at his boyhood home at Claremont, N. H. He never married, and the only surviving member of his immediate family is his sister, Elizabeth G. Phelps.

Mr. Phelps was elected a Member of the American Society of Civil Engineers on October 2, 1907.

HENRY TEGMEYER PORTER, M. Am. Soc. C. E.[1]

Died January 11, 1932

Henry Tegmeyer Porter was born in Piedmont, W. Va., on January 10, 1859, the son of William E. and Sarah (Paxson) Porter.

Mr. Porter was graduated from the Baltimore (Md.) City College in 1879, and began his engineering career in 1881 as Chainman with the West Virginia Central and Pittsburg Railway Company. In December of the same year, he became Transitman and Assistant Engineer with the New York, West Shore and Buffalo Railway Company, remaining in this position until February, 1884, during which time he was engaged largely on construction work.

In 1884 and 1885, he was Transitman with the West Virginia Central and Pittsburg and the South Pennsylvania Railway Companies and, during part of 1885 and 1886, was Contractor's Engineer for Beckwith, Quackenbush, and Company, on the construction of the Howard University Tunnel, Washington, D. C.

---

[1] Memoir prepared by W. S. McFetridge, M. Am. Soc. C. E., and F. R. S. Layng, Assoc. M. Am. Soc. C. E.

From 1886 to 1896, Mr. Porter was Resident Engineer and General Roadmaster of the Toledo, St. Louis and Kansas City Railroad Company, during which time the road was largely rebuilt and the track relaid with heavier rails. For a short time in 1897, he was Chief Engineer of the Chicago, Peoria and St. Louis Railroad Company, and then served as Engineer with the Continuous Rail Joint Company of America. In October, 1897, he entered the service of The Pittsburg, Bessemer and Lake Erie (now the Bessemer and Lake Erie) Railroad Company, as Engineer, Maintenance of Way, and, in 1898, he was appointed Chief Engineer of the same Company, which position he held until his retirement from active service on April 30, 1931.

From 1902 to 1906, Mr. Porter was also Chief Engineer of the Western Allegheny Railroad Company, extending from Kaylor to Newcastle, Pa. This road was located and constructed under his direction.

During Mr. Porter's long service of nearly thirty-four years with the Bessemer and Lake Erie Railroad Company, many major projects, changes of line, and other improvements were carried out under his direction. He was an early advocate of the use of heavier loadings in the design of bridges, and one of the first bridges, an 154-ft. through truss bridge, built shortly after he became Chief Engineer, was designed for Cooper's E-60 loading, and the Osgood Viaduct, built in 1901, was designed for the same loading.

Among the many projects carried out under his direction may be noted the following: The principal repair shops at Greenville, Pa., occupying 61 acres of land and constituting a modern up-to-date shop layout; the construction of the Bessemer and Lake Erie Railroad from Kremis to K O Junction, Pa., in 1901 and 1902 (this Company later took over the operation of The Pittsburg, Bessemer, and Lake Erie Railroad); the change of line from Culmerville to Cunningham, Pa., to improve alignment and grades, and which includes the Bull Creek Fill, 180 ft. high, containing 5 000 000 cu. yd. of material; and the replacement of the single-track bridge over the Allegheny River, at River Valley, Pa., with a double-track bridge built for Cooper's E-75 loading. The single-track bridge had a viaduct approach at the north end and three 350-ft., one 520-ft., and one 207-ft. deck truss spans over the river; the total length, including the viaduct, was 3 538 ft. The new bridge had the same length of spans over the river, with one 273-ft. span, one 153-ft. span, and one 60-ft. span added at the north end; the remainder of the viaduct was filled. The new bridge was erected alongside the old one, on the extensions of piers required for double-track, and the main spans were built in two continuous sections erected as cantilevers, one section, 1 140 ft. long, and one section, 969 ft. long, each covering three spans; the other short spans at the north end were erected in the usual manner. Each section was moved laterally into place after the old bridge was torn down. The total weight in the 1 140-ft. section was 13 000 000 lb. and this section was moved into position in 27 min. In the 969-ft. section, the weight moved was 10 200 000 lb. The horizontal movement was 16 ft. 3 in. The embankment replacing the viaduct contains 1 382 000 cu. yd. This bridge was completed in 1918.

Another project was the enlargement of the Inner Basin at Conneaut Harbor, Ohio, where the ore docks of the Railroad Company are located. This work was completed in 1926 and included one of the heaviest and strongest reinforced concrete docks built on the Great Lakes. The dock front is constructed on piers and caissons, all of reinforced concrete, with their foundations carried to rock, the greatest depth being 41 ft. below mean lake level. This dock was built to carry ore-unloading machines, much larger and heavier than any used at the Harbor up to that time.

Other work on which Mr. Porter was engaged included: The new line from Filer to Coolspring, Pa., completed in 1929, which was named the Porter Cut-Off in his honor; in addition, many other smaller projects and changes were made, the road was double-tracked from North Bessemer to Conneaut Harbor and largely rebuilt, and the work done under his direction had much to do with enabling the Bessemer and Lake Erie Railroad to take its present position as a heavy tonnage line.

Mr. Porter was frequently consulted on engineering projects, especially those concerning his own community. He was Consulting Engineer on the Ohl Street Bridge, over the Shenango River, for the Borough of Greenville, and he was also consulted in regard to some of the highway bridges in county and other projects.

He was one of the original workers on the Pymatuming Conservation Project for building the Pymatuming Dam and Storage Reservoir, near Linesville, Pa., to provide flood control and water conservation for the Shenango Valley, and as a member of the Executive Committee of the Beaver and Shenango Water Conservation Association, he supported it from the start, about 1912, to its ultimate consummation and the beginning of construction work.

As a member of the Borough Council of Greenville for four years, he rendered valuable service to the community. He was a member of the Presbyterian Church of Greenville and always took a deep and sincere interest in its work.

Mr. Porter was a member of the International Railway Congress, American Railway Engineering Association, Engineers Society of Western Pennsylvania, and the Railway Club of Pittsburgh. Other organizations and clubs of which he was a member were: The Pennsylvania Society, Keystone Athletic Club of Pittsburgh, and American Iron and Steel Institute.

Locally, Mr. Porter belonged to the Greenville Country Club, Kiwanis Club, and Railway Club of Greenville. He was also a Director of the Greenville National Bank. Among Masonic Bodies he was affiliated with Eureka Lodge No. 290, F. and A. M., Mount Royal Chapter No. 212, Mount Calvary Commandery No. 67, Knights Templars, and the Acacia Club.

Mr. Porter exemplified and advocated high standards of honor, and diligent work for his profession. He was always active in, and gave of his time and experience to all, community affairs, and his public spirit led him into active participation in the activities of church, town, and business groups.

On September 23, 1886, he was married to Annie Hall, who died in Greenville on December 13, 1930. One son, William Hall Porter, of Youngstown, Ohio, and one daughter, Margaret E. Porter, at home, survive him.

Mr. Porter was elected a Member of the American Society of Civil Engineers on April 1, 1903.

HARRY LONGYEAR PRESTON, M. Am. Soc. C. E.[1]

Died March 25, 1930

Harry Longyear Preston, the son of Otis Marshall and Angeline (Lawrence) Preston, was born in Roxbury, N. Y., on November 29, 1877.

He was a descendant of Thomas Rogers who came over in the *Mayflower,* the same Thomas Rogers who is mentioned in Governor Bradford's Memoirs. The first Preston came to this country on April 8, 1635, from Cripplegate, London, on the ship *Elizabeth of London,* William Slagg, Master, An ancestress, named Sarah Lord, suffered a long imprisonment on the charge of witchcraft in 1692. Mr. Preston was a son of the American Revolution, with five ancestors who fought in that particular war. His great-grandfather was a Major General serving on the staff of Col. Jonathan Holman, when the regiment marched at the Rhode Island Alarm. The first of the family to settle in Roxbury, N. Y., was John Moore, who was a great friend of Joseph Brant, the Indian Chieftain, and credit is given to John Moore for saving Roxbury from destruction by Walter Butler and Brant at the time of the Cherry Valley Massacre. John Moore's daughter, Jean, was Mr. Preston's great-great-grandmother.

Mr. Preston was graduated from Sheffield Scientific School of Yale University in 1900 with the degree of Bachelor of Philosophy in Civil Engineering. In July 1900, he entered the service of the Pennsylvania Railroad, Lines West of Pittsburgh, beginning his engineering experience as a Rodman. In April, 1901, he left the Pennsylvania Railroad Company to accept a position as Assistant Engineer on construction for Jones and Laughlin, Limited, of Pittsburgh, Pa., in which position he had charge of a field party on steel mill and open-hearth furnace construction.

From March, 1902, until May, 1905, Mr. Preston was an Assistant Engineer for the Pittsburgh and Lake Erie Railroad Company, in charge of the construction of 10 miles of third and fourth-tracking, gravity yard, and shops, together with other general work.

In May, 1905, he accepted a position with the New York Central and Hudson River Railroad Company (later The New York Central System), acting as Transitman and Draftsman until November of that year, when he was made an Assistant Engineer in charge of construction work. He remained in the service of the New York Central and Hudson River Railroad Company until April, 1913, and during the period, May, 1905, to July, 1909, was in charge of the following construction work: Grade-crossing elimination, Tilly Foster Mines, Putnam Division; double-tracking, Goldens Bridge to Brewster, Harlem Division; Poughkeepsie improvement, Hudson Division; double-tracking, Salina to Liverpool, Rome, Watertown, and Ogdensburg Division; grade-crossing elimination, Grant Avenue, Sennett, Auburn Branch; and a 20-stall engine house, at Syracuse, N. Y. In July, 1909, Mr. Preston was made Assistant District Engineer, which title was changed to Resident Engineer on January 1, 1910, which position he held until he resigned on April 15, 1913. During the period from July, 1909, to April, 1913, he had charge of all the construction work in the vicinity of Syracuse, including third and fourth-tracking and grade revision of the Syracuse Junction Railroad, the construction of the Belle Isle Yard, the Barge Canal crossing of the West Shore Railroad, at Montezuma, N. Y., and a car repair shop, at Oswego, N. Y.

---

[1] Memoir prepared by E. B. Menuez, Valuation Engr., N. Y. Central Railroad, Lines Buffalo and East.

In April, 1913, Mr. Preston became Owner and Manager of the Jordan Wheelbarrow Company, engaged in the manufacture of agricultural implements, and continued in this work until the Company was discontinued in 1917.

On May 16, 1917, he returned to the New York Central Railroad Company as Assistant Engineer in the Valuation Department, taking charge of the field inventory of the New York District, which inventory was made by the Railroad Company at the request of the Bureau of Valuation, Interstate Commerce Commission. In September, 1917, Mr. Preston was promoted to the position of Field Engineer, Lines Buffalo and East, in charge of the Pilot Engineers and forces accompanying the field parties of the Bureau of Valuation, that were making an inventory of the railroad property.

On August 9, 1918, he was given a leave of absence for military duty and entered the military service of the United States as Captain of Engineers, U. S. Army, in command of Company K, 22d Engineers. In February, 1919, he was made Supply Officer, 4th Battalion, 22d Engineers, American Expeditionary Forces, France, Light Railway Division, Second Army, Toul Sector.

In July, 1919, Mr. Preston returned to the service of the New York Central Railroad Company, in the Valuation Department, Lines Buffalo and East, as Assistant Engineer in charge of grading distribution and reproduction program, and in January, 1925, was made one of the Assistant Valuation Engineers. During 1924, he was stationed in Washington, D. C., in charge of the forces co-operating with the Bureau of Valuation, in determining the quantities to be included in the proposed engineering report, and in 1926, during the conference with the Bureau of Valuation, in connection with the revision of the preliminary Engineering Report, he was in charge of certain negotiations and checking principally in regard to grading and allied items.

In 1928, he was in charge of the Railroad Company's forces engaged in the field inventory of the Hudson River Connecting Railroad which, having been constructed subsequent to the valuation date of the New York Central, was inventoried by the Bureau of Valuation as a separate corporate body. At the time of his death, Mr. Preston was engaged on certain details of this work.

Mr. Preston was a loyal friend and was highly esteemed and respected by all who came in contact with him. His personality was of a superior type and his integrity and sincerity without a blemish. At his death his family and many friends suffered a severe loss.

R. E. Dougherty, M. Am. Soc. C. E., Vice-President, New York Central Lines, who brought Mr. Preston into that service, writes as follows:

> "It was my privilege to initially engage Mr. Preston for his New York Central service shortly after I had been appointed in charge of construction in the Eastern District of the New York Central. It was my own first appointment to responsibility and I was naturally much concerned about those who should collaborate with me.
>
> "Mr. Preston quickly proved to be a man of keen intelligence, good judgment, and fine character. Outside of our business relations he and I established a personal friendship which continued until his death.
>
> "His passing is a very distinct loss to the New York Central and to his friends who will not forget him."

Another of his many friends writes:

> "My acquaintance with him dates back to the early days of Federal Railway Valuation work. My association with him was of a peculiarly intimate nature, and in my acquaintance with thousands of engineers engaged in valuation work, I have found no one endowed with a greater spirit of co-operation, fairness, and desire to intelligently arrive at facts in connection with the work at hand.
>
> "Mr. Preston was not only a splendid engineer, thoroughly equipped with a knowledge of his road, but of fundamentals which go to make up a successful valuation engineer. All of his conferences were actuated with a spirit of fairness to the public as well as to the railroad that he served. He possessed to a high degree that engineering element known as diplomacy, and at the same time was earnest and firm in his convictions as to what was right and just in connection with his work. The engineering profession loses a splendid member in the passing of Mr. Preston."

From a letter written by another friend, the following is quoted:

> "I will say that my acquaintance with Mr. Preston covered a term of perhaps eight years. Prior to that time I had heard of him as being an outstanding man among a group of men of the highest character. In my contact with the various valuation men from all over the country I have become acquainted with many men of the highest character and among them Mr. Preston was perhaps the outstanding man as a gentleman, a man who said nothing but good of everybody and who had the ability to play the game in this work."

He was married on September 8, 1903, to Ellen Marie Tracy, who died November 16, 1916. On September 15, 1920, he was married to Nona Nelson, who survives him.

Mr. Preston was elected an Associate Member of the American Society of Civil Engineers on April 1, 1908, and a Member on October 3, 1922.

ALBERT REESOR RAYMER, M. Am. Soc. C. E.[1]

DIED AUGUST 10, 1931

Albert Reesor Raymer, the son of John N. and Christina Raymer, was born on December 1, 1862, at Markham, Ont., Canada. He attended the Markham High School and was graduated from the University of Toronto, Toronto, Ont., Canada, in 1884, with the degree of Civil Engineer, entering at once into the practice of his profession.

From 1884 to 1887, Mr. Raymer was Rodman on Location and Resident Engineer on Construction of the Northern and Pacific Junction Railway (later, the Canadian National Railway); 1887 and 1888, Leveler on Location and Office Engineer in the office of the Chief Engineer on Construction, International Railway of Maine (later, the Canadian Pacific Railway); 1888, Office Engineer on Location, Toronto, Hamilton and Buffalo Railway, with headquarters at Hamilton, Ont., Canada; 1889, Locating Engineer, Grand Trunk Railway (later, the Canadian National Railway), from Waterloo to Elmira, Ont.; 1889 to 1891, Office Engineer on Construction, Cumberland Valley Extension of the Louisville and Nashville Railroad, from Cumberland Gap, Tenn., to Big Stone Gap, Va.; and 1891 to 1896, Assistant Engineer in charge of office and field work on maintenance, Lake Shore and Michigan Southern Railway (later, the New York Central Railroad), Toledo, Ohio. In 1896, he was naturalized as a citizen of the United States.

Mr. Raymer went to the Pittsburgh and Lake Erie Railroad Company (New York Central Lines) on August 19, 1896, as Assistant Engineer. On February 1, 1901, he was appointed Assistant Chief Engineer and held that position until March 1, 1920, at which time he was made Chief Engineer. He was appointed Assistant Vice-President and Chief Engineer on July 1, 1926, which position he held until July 1, 1931, when he was made Assistant Vice-President and continued as such until his death.

During his tenure of office as Assistant Chief Engineer Mr. Raymer was directly in charge of all engineering design which included the design and construction of large terminal, storage, and classification yards, with roundhouses, locomotive and car repair shops, etc., at various points along the road.

One of the major engineering structures built during that time was the pin-connected cantilever bridge over the Ohio River, at Beaver, Pa. This bridge, on account of the many novel features embodied in its design, attracted the attention of the Engineering Profession at the time of its construction. The substructure was designed under Mr. Raymer's personal supervision, and he prepared and presented a paper on the subject, entitled "The Substructure of the Pittsburgh and Lake Erie Railroad Bridge Over the Ohio River at Beaver, Pa.," before the Structural Section of the Engineers' Society of Western Pennsylvania.[2] He also prepared and presented a paper entitled "The Pittsburgh and Lake Erie Railroad Cantilever Bridge

---

[1] Memoir prepared by R. P. Forsberg and E. K. Morse, Members, Am. Soc. C. E.

[2] *Proceedings*, Engrs.' Soc. of Western Pennsylvania, Vol. 26, No. 1 (January 4, 1910).

Over the Ohio River at Beaver, Pa.," at the meeting of the American Society of Civil Engineers on March 1, 1911.[3]

Designs for other important engineering work made during his tenure of office included plans for a complete terminal layout in Pittsburgh, Pa., the principal items being a modern terminal passenger station and general office building, a power plant, and a large fireproof storage warehouse. Designs were also prepared by Mr. Raymer, covering the construction of several branch and tributary lines, the principal one of the latter being the Lake Erie and Eastern Railroad, a part of which is located through Youngstown, Ohio, crossing streets, railroads, several river crossings, etc., and involving many engineering problems. He designed, and under date of April 19, 1904, secured patents for a method of cleaning and restoring boilers to service condition.

Mr. Raymer was, in the strictest sense of the term, a Christian gentleman, always courteous, affable, and democratic. Inherently an Engineer, he derived genuine pleasure from the study and solution of all problems that came before him, usually treating them in an original manner. He possessed that trait which every engineer should covet, namely, the faculty of blending the ideal with the practical in his designs and in their execution.

He contributed his engineering knowledge and skill in a most generous manner, not only to the Company with which he was connected for a long term of years, but to the various organizations with which he was affiliated, and especially to any young engineer who came to him for counsel or advice.

He was President of the Beech Creek Railroad Company; the Beech Creek Extension Railroad Company; the Shenango Valley Railroad Company; and the Stewart Railroad Company; and a member of the Board of Directors of the Pittsburgh, McKeesport, and Youghiogheny Railroad Company; the Pittsburgh, Chartiers, and Youghiogheny Railway Company; the Chartiers Southern Railway Company; the Mahoning State Line Railroad Company; the Greene County Railroad Company; and the Pittsburgh and Clearfield Railroad Company.

Mr. Raymer was also a member of the Board of Directors and Past-President of the Standard Chemical Company of Pittsburgh, Pa.; Chairman of the Bridge Engineers' Committee of the New York Central Lines, which position he held continuously from the formation of that Committee in 1907 until his death; and a member of the Engineering Committee of the New York Central Lines.

He was a member and Past-President of the Engineers' Society of Western Pennsylvania; a member of the American Railway Engineering Association; the Duquesne Club, of Pittsburgh; and the Beaver Valley Country Club, of Beaver Falls, Pa.

He was a Thirty-second Degree Mason, a member of Pennsylvania Consistory, Valley of Pittsburgh, and A. A. O. N. M. S., Syria Temple, of Pittsburgh, and a member of the Methodist Episcopal Church, of Beaver, Pa.

Mr. Raymer was married to Frances Emmeline Hutcheson, who, with three children, Edith Alberta (Mrs. Frank T. Underhill), of Summit, N. J., Paul

---

[3] *Transactions*, Am. Soc. C. E., Vol. LXXIII (1911), p. 136.

Hutcheson Raymer, of New York, N. Y., and Dr. John George Raymer, of Norwich, Conn., survives him.

Mr. Raymer was elected a Member of the American Society of Civil Engineers on March 1, 1910, and served as a Director of the Society from 1925 to 1927.

ABRAHAM MOREAU REYNOLDS, M. Am. Soc. C. E.[1]

DIED APRIL 7, 1932

Abraham Moreau Reynolds was born in Newark, N. J., on December 1, 1869, the son of Abraham Moreau and Anna (Mason) Reynolds. He attended the Newark public schools and was graduated in a special mathematical course at Pingree Institute, Elizabeth, N. J., in 1888.

Mr. Reynolds began his engineering career, in February, 1888, with the firm of Earle and Harrison, Jersey City, N. J., which had an extensive business as Engineers and Surveyors in Northern New Jersey. While with this firm, he was engaged in a survey of the Raritan River Railway.

He left the employ of Earle and Harrison in the fall of 1892 to accept a position as Assistant Engineer with the Lehigh and Hudson River Railroad Company, at Warwick, N. Y., where he remained until March, 1895. At that time he was appointed Division Engineer on highway construction in Morris County, New Jersey, where he had charge of making surveys and plans for the improvement of about ten miles of county highways.

In August, 1895, Mr. Reynolds accepted a position with the Essex County Park Commission, at Newark, N. J., as Assistant Engineer. This Commission had just started its work of developing parks in Essex County and Mr. Reynolds continued with it until he retired in August, 1931, on account of ill health. From 1895 until December, 1901, he had charge of constructing three parks in the System and, at that time, was appointed Chief Engineer for the Commission in charge of all construction. In January, 1906, the Park Commission made him Superintendent of Maintenance, as well as continuing him as Chief Engineer, and he served in this capacity for more than twenty-five years, until his retirement.

The successful development, as well as the continued excellent state of maintenance of the parks of the Essex County Park Commission, was due to Mr. Reynolds more than any other individual connected with the System. His conscientious devotion to his work, his wonderful business ability, and his engineering skill were greatly appreciated by members of the Park Commission. This appreciation was expressed by the Commission in a handsomely embossed resolution presented to him at the time of his retirement.

Mr. Reynolds was a member of the American Society of Municipal Engineers, the New Jersey Society of Professional Engineers and Land Surveyors, and was on the Consulting Staff of The Regional Plan of New York and Its Environs, for several years prior to his retirement. He was also for many years a member of the Glen Ridge Country Club and the Down Town Club, of Newark.

---

[1] Memoir prepared by J. H. Philips, M. Am. Soc. C. E.

Besides his widow, Emily Sanford Reynolds, to whom he was married in 1899, Mr. Reynolds is survived by two sisters, Josephine and Clementine Reynolds, of Warwick, N. Y.

Mr. Reynolds was elected a Member of the American Society of Civil Engineers on November 30, 1909.

KNUD SOPHUS RISER, M. Am. Soc. C. E.[1]

Died November 1, 1931

Knud Sophus Riser was born at Horten, Norway, on August 15, 1858. His father was a lawyer, and for many years Chief of the Auditing Department in the Custom House at the Norwegian Capital. He had an older brother and one sister, who describe the home surroundings as unusually quiet and religious. He was graduated from the Polytechnic Institute at Christiania (now called Oslo), Norway, in 1880. He came to America soon afterward for, in 1881, he was employed on a railroad survey for the Pittsburgh, Alleghany, and McKeysport Coal Company, which he always spoke of as his "first job."

Subsequently, he served as a Draftsman with the Edgemoor Bridge Works, at Edgemoor, Del., and, later, with the Philadelphia (Pa.) Bridge Works. For three years Mr. Riser was employed as Assistant Engineer at the Milwaukee (Wis.) Bridge and Iron Works.

He became Chief Engineer of the Clinton Bridge and Iron Company, at Clinton, Iowa, in June, 1889, and among the larger of his works may be listed the design of a bridge across the Mississippi River, at La Crosse, Wis., consisting of three fixed and a single draw span of 450 ft.; also, the High Bridge, at Clinton, consisting of six spans of 150 ft. each, two spans of 210 ft. each, one span of 219 ft., and a cantilever span of 420 ft., resting on rocker towers, 55 ft. high, and which, together with an iron trestle approach, had a total length of 3 300 ft.

In 1893 he went to Detroit, Mich., and engaged in private practice, as a Consulting Bridge Engineer, until 1896 when he was appointed Engineer of Construction with the Penn Bridge Company, at Beaver Falls, Pa.

In 1901, Mr. Riser went to Grand Rapids, Mich., where he organized and became President and Chief Engineer of the Grand Rapids Bridge Company, which position he retained until 1907, when he again took up the private practice of engineering as a Civil and Architectural Engineer.

---

[1] Memoir prepared by his Fellow Members of the Society residing in Grand Rapids, Mich.

With his high regard for professional ethics Mr. Riser was never aggressive in seeking business. All work had to come to him, and he personally attended to every detail of it. In Grand Rapids, he earned the richly deserved reputation of "Court of Final Resort" in all problems involving steel design beyond the experience of local architects. For years, the City Building Inspector (who was not then a technically trained engineer) referred to Mr. Riser all difficult questions of structural design. Mr. Riser's reports defied political expediency. On one occasion he showed that with a few minor repairs a certain bridge was good for another fifty years' service, and local aldermen were compelled to employ outside talent to sanction the desired building of a new bridge on that site. The steel work for a new theater was delivered and in process of erection before he was called on to check the design, and the mistakes he compelled the steelwork sales engineer to rectify developed into a comedy when he found even the foundation reinforcement placed on the wrong side. He regarded it a mistake to print formulas in handbooks, for, in his opinion, unless each specific problem was sufficiently understood to derive the formula, the designer was not qualified to render judgment.

Mr. Riser achieved maximum economy of construction in designing the Street Railway Company's Bridge across the Grand River, using piers of twin steel cylinders sunk to firm bottom by interior mucking and then filled with concrete. The steel framework of many local high buildings, notably the Herpolsheimer Building, was his design, although his name was seldom mentioned with those of the architects. Another example is the steel work in the car-ferry dock of the State Highway Department, at Mackinaw City, Mich. The Ann Street Bridge, in Grand Rapids, was entirely his design.

In 1888, he was married to Sarah Evans, of Pottstown, Pa., who died on November 28, 1928. They had no children, and Mr. Riser felt her loss very keenly. At home, his greatest delight was in the perusal of his technical books.

His circle of intimate friends was small, but in that circle Mr. Riser was universally beloved. The social side of his nature was not developed sufficiently to overcome his innate modesty, and he avoided all publicity and seldom referred to his personal accomplishments. He could not be induced to attend Society meetings even when they were held in his part of the country, and he never attended the meetings of the Grand Rapids Engineers' Club, the requirements of which for membership failed to meet his high professional ideals.

Mr. Riser was killed on November 1, 1931, when the automobile he was driving was struck by a train at the Michigan Central crossing, at Dutton, Mich.

He was a member of the Masonic Fraternity, his Blue Lodge being York No. 410, in Grand Rapids, and his Chapter, Harmony No. 206, of Beaver Falls, Pa. He was a Knight Templar in De Molai Commandery, of Grand Rapids, which conducted his funeral services. In his passing, his professional associates mourn the loss of their ablest member.

Mr. Riser was elected a Member of the American Society of Civil Engineers on February 3, 1892.

EARL IVAN ROBERTS, M. Am. Soc. C. E.[1]

DIED MAY 4, 1932

Earl Ivan Roberts was born on September 5, 1890, at Bristol, Ohio. He was the son of Charles H. and Ella (Davis) Roberts.

Mr. Roberts attended the public schools and High School at McConnelsville, Ohio, from which he was graduated in 1910. Following a two-year period, during which he taught in a rural school near his birthplace, he entered Ohio State University, at Columbus, Ohio, and completed the course in the Sanitary Engineering Department, graduating in 1916 with the degree of Bachelor of Civil Engineering.

His first work after graduation was with W. J. Sherman, M. Am. Soc. C. E., Consulting Engineer, Toledo, Ohio, on street paving; later, Mr. Roberts became Topographer and Resident Engineer on sewer construction in the Sanitary Engineering Department of Lucas County, Ohio.

In March, 1917, he went with the Ohio State Department of Health as Assistant Engineer, where his duties required him to check designs and make inspections of water supplies, sewerage systems, and sewage treatment works.

In February, 1918, Mr. Roberts enlisted as a Private in the Medical Corps, U. S. Army, where his devotion to duty, cheerful disposition, and technical ability quickly won for him the attention of his superior officers, and, in March, he was promoted to Sergeant, First Class, in the Sanitary Corps, U. S. Army, in charge of the supervision of water-analysis laboratories. Soon after this promotion, Mr. Roberts was transferred to France. In October, 1918, he was commissioned Second Lieutenant in the Sanitary Corps and placed in charge of water laboratories and the supervision of operation of filtration plants, in which capacity he remained until May, 1919, when he was commissioned First Lieutenant. In June, 1919, his services no longer being required with the American Expeditionary Force, Lieutenant Roberts was returned to the United States, and was honorably discharged from the Army in July.

In August, 1919, Mr. Roberts again took up his work with the Ohio State Department of Health, and remained with the Department until March, 1924, in charge of the supervision of operation of water purification works.

From March, 1924, to March, 1927, he was associated with William G. Clark, Jun. Am. Soc. C. E., Consulting Engineer, of Toledo, during which period he was in responsible charge of the design and supervision of construction of water-works at Barberton, Piqua, and Fremont, Ohio, and Decatur, Ill.

In March, 1927, Mr. Roberts became an associate in the organization of H. P. Jones and Company, Engineers, of Toledo, and was with this firm until his death, as Engineer in charge of design and construction of sewerage, sewage treatment, and water purification works. During this period he played an important part in the design of works of large magnitude at Toledo, Findlay, and Lima, Ohio, all of which in no small degree bear silent witness to his skill as an Engineer, and his loyalty to the interests of his clients and business associates.

---

[1] Memoir prepared by Harvey P. Jones, M. Am. Soc. C. E.

Mr. Roberts met a tragic death in an heroic but futile attempt to rescue a plant operator at the sewage treatment works at Lima, Ohio. The plant operator had descended a shallow manhole alongside one of the digesters for the purpose of taking a sample of the sludge. After having taken the sample he came to the surface and passed it to one of the other employees who was assisting him, when he slipped back to the bottom, apparently having been partly overcome by gas which had accumulated in the manhole. Striking his head on the concrete floor, he suffered a fractured skull from which he later died. Mr. Roberts, who at the time was about a quarter of a mile away from the scene, hearing the alarm sent out by the operator's assistant, ran to the spot and after issuing orders that an ambulance and the rescue squad of the local gas company be sent for, descended into the manhole, hoisted the operator's body on his shoulders, and started out. He had almost accomplished his aim, when he himself was overome by the gas, slipped back into the chamber, and never regained consciousness despite all the efforts which were made to resuscitate him after his body was brought to the surface.

Mr. Roberts was admired and respected by all who knew him, and his friends loved him. His technical ability was rapidly winning high recognition in his profession to which he had always been an honor. He lived as unselfishly as he died, and his last act is by far the best eulogy to him that could be written.

He was married on June 15, 1922, to Marie S. Hoffman, at McConnelsville, Ohio. He is survived by his widow, and his daughter, Henrietta Jane, aged four, of Toledo; his parents, Mr. and Mrs. C. H. Roberts, of McConnelsville, and two sisters, Vera and Dorothy Roberts, of Cleveland, Ohio.

Mr. Roberts was elected a Member of the American Society of Civil Engineers on November 14, 1927.

WILLIAM LAWRENCE SAUNDERS, M. Am. Soc. C. E.[1]

Died June 25, 1931

William Lawrence Saunders, the son of William Trebell and Eliza (Morton) Saunders, was born on November 1, 1856, at Columbus, Ga. He was the grand-nephew of Robert Saunders, the fourteenth President of William and Mary College, at Williamsburg, Va., and a descendant of Sir Edward Saunders, one of the Knights of the Horseshoe, who discovered the Alleghany Mountains. His ancestors landed with the Jamestown Expedition, at Jamestown, Va.

---

[1] Memoir prepared from information supplied by the Ingersoll-Rand Co., New York, N. Y., and on file at the Headquarters of the Society.

Mr. Saunders was graduated from the University of Pennsylvania in 1876 with the degree of Bachelor of Science, and, in 1911, he received the degree of Doctor of Science, from the University. Previous to his graduation, he was Editor-in-Chief of *University Magazine* and the Class Poet. In 1925, he received the honor cup of the University of Pennsylvania, awarded annually to its most distinguished alumnus.

He was engaged in newspaper work in Philadelphia, Pa., from 1876 to 1878, but, in the latter year, he left this field for an engineering career which he began with the National Storage Company of Communipaw, N. J., as Engineer in Charge of Dock Construction at Black Tom Island, New York Harbor. He designed and patented apparatus for subaqueous drilling with a tube and water-jet system now in general use.

In 1882, he was appointed Engineer for the Ingersoll Rock Drill Company. Mr. Saunders subsequently served as Secretary, Vice-President, and Director of the Ingersoll-Sergeant Drill Company, and President of the Haesler Tool Company and the New York Imperial Tool Company. When the Ingersoll-Sergeant Drill Company was succeeded by the Ingersoll-Rand Company, he became President and, ultimately, Chairman of the Board of Directors of this firm, of which he was also Director.

In addition to his device for drilling rock under water, he was also the inventor of the Ingersoll track and bar channelers and gadders for quarrying dimension stone, marble, and limestone. He was interested particularly in the application of compressed air to engineering problems and relative to this pursuit made two balloon ascensions, reaching a height of 3½ miles, which necessitated his remaining above the earth over night. He also invented the radial axe system for coal mining and the method of pumping liquids by compressed air.

Mr. Saunders was for some time Editor of *The Compressed Air Magazine* and author of a number of books on compressed-air information and compressed-air production. He was also co-author of "The Subways and Tunnels of New York," "Rock Drilling," and numerous other pamphlets and articles in *Engineering* and other journals.

Mr. Saunders' later life comprises a record of distinguished public service. One of the most important public positions which he occupied was that of Chairman of the Naval Consulting Board to which he was appointed by President Wilson in 1915 and which he filled for many years. A prominent member of the Democratic party in New Jersey, he had been a member of the State Democratic Committee, and in the Presidential campaign of 1916, he was one of New Jersey's representatives on the Democratic National Committee. He had been twice Mayor of North Plainfield, N. J., and maintained his home in Plainfield.

During the World War, he was one of the organizers and a member of the Military Engineering Committee which at its own expense equipped a regiment and sent it to France. This was the first regiment of American engineers to pass through London, England, also the first in action at the Front. Mr. Saunders was an expert on submarine warfare and equipped the *Lucia,* an Austrian ship interned in an American port at the beginning of the war, as "an unsinkable ship." His theory was that 12 000 boxes fastened to the ship's framework below the water line would keep her afloat no matter how riddled she might be by torpedoes. This conviction, however, remained untested. Although the *Lucia* carried several contingents of troops to France, she was never struck by a torpedo. During the war, he also served on the District Committee on Capital Issues of the Federal Reserve Board and on the Advisory Board of the Fuel Administration Committee.

Mr. Saunders was a leader in the crusade against cancer and, in 1926, announced through the American Society for the Control of Cancer that he would present a prize of $50 000 for the discovery of the nature of human cancer and an equal amount for the discovery of a positive cure. After two years, he was convinced of the futility of the search and withdrew his offer.

He was a Past-President of the American Manufacturers' Export Association and had also served as President of the American Institute of Mining and Metallurgical Engineers. In 1926, he founded the Mining Medal of the Institute to recognize achievement in mining. He was a former Governor Director and Deputy Chairman of the Federal Reserve Bank of New York and had been a member of the New Jersey Harbor Commission, the New Jersey Board of Commerce and Navigation, and the Advisory Committee of the Federal Trade Commission. He was a former President, Trustee, and a member of the Finance Committee of United Engineering Society, and a member of the Chamber of Commerce of the United States, the National Foreign Trade Council, and the National Civic Federation. He was also a Fellow of the American Geographical Society, the Academy of Political Science, and the American Academy of Political and Social Science.

Mr. Saunders was a former President of the Machinery Club, and a member of the Engineers, India House, and University Clubs, and the University of Pennsylvania Club of New York, N. Y., and a Director of the Penn Alumni Realty Corporation. He was also a member of the Gogebic Country Club, of Ironwood, Mich.

He was married at Narragansett Pier, R. I., in 1886, to Bertha Louise Gaston, who died in December, 1906. He was embarked on a world cruise when he died in his seventy-fourth year in Teneriffe, Canary Islands. He is survived by two daughters, Mrs. Maxwell Evarts Perkins and Mrs. John E. Lancaster, Jr.

Mr. Saunders was elected a Member of the American Society of Civil Engineers on November 3, 1886.

ANTON SCHNEIDER, M. Am. Soc. C. E.[1]

Died November 28, 1929

Anton Schneider was born on January 11, 1871, at Summit Hill, Pa. His grandfather was one of the patriotic citizens for whom the United States is indebted to the German Revolution of 1848. These citizens transferred their loyalty from the Mother Country, which rejected their ideas of freedom, to the new home of liberty and lavished on their adopted country the enthusiastic devotion to its principles which had been denied them at home. This patriotism was inherited by the grandson and was demonstrated in his efforts to do his part in the World War against those who were still contesting the right of individual freedom of thought and action. Mr. Schneider's mother, Sarah (Wintersteen) Schneider, was of Dutch extraction, the family having been early settlers of Pennsylvania; one of them was a victim of the Wyoming Massacre.

---

[1] Memoir prepared by Charles Carroll Brown, M. Am. Soc. C. E.

The record of Anton Schneider, the engineer, shows graduation from Lehigh University with the degree of Civil Engineer in 1892, and with vacation experiences as Chainman and Draftsman on the Central Railroad of New Jersey and in the Pencoyd Bridge Works. His employment after graduation began with the Utah and Idaho Division of the Union Pacific System on general maintenance of way, location of spurs to mines, etc. He also designed and supervised the construction of several bridges during the period from 1892 to 1898 for organizations which were affiliated with the Railroad System. These years also included work as Draftsman for the Pioneer Electric Power Company, Ogden, Utah, and as Assistant Engineer on the Oregon Short Line Railway.

Mr. Schneider enlisted for the Spanish-American War in the 2d United States Volunteer Engineers, stationed at Honolulu, Hawaii, and was rapidly promoted during the years 1898 and 1899 from Private to Sergeant, Second Lieutenant, and First Lieutenant.

The conclusion of the war gave him the opportunity of returning to transportation engineering under the former Chief Engineer of the Union Pacific System, George H. Pegram, Past-President, Am. Soc. C. E., who had become Chief Engineer of the Rapid Transit Lines, of New York, N. Y. Mr. Schneider served as Resident Engineer on elevated railroad construction on the Manhattan Elevated Railroad, including elevated tracks, yards, shop, terminal and passenger station buildings on the Third Avenue and Bronx Park Extensions, and in the 179th Street yards and shops.

He resigned late in 1902 to accept a position on the construction of the Cerro de Pasco Railway at the summit of the Andes Mountains in Peru—the highest railroad in the world. He served two months as Division Engineer and ten months as Acting Chief Engineer. Although the road was only 84 miles long it offered unusual opportunities for practice in surmounting unique difficulties. The construction period was short and the elevation too high for comfortable living—impossible for his family—so that he returned in 1904 to his position on the Manhattan Elevated Railroad in charge of station finish in New York subways. In 1905, he was transferred to the Rapid Transit Subway Construction Company, an associated company of what had then become the Interborough Rapid Transit Company. His work with this Company was as Division Engineer in charge of the East River Tunnels at the Battery, which work he followed from the bulkheads at the river bank to the completion of the tunnels in January, 1908.

In May, 1908, Mr. Schneider resigned to accept a position as Superintendent of the Pierce Phosphate Company, at Pierce, Fla. The phosphate mining industry in Florida, at this time, was more or less in an experimental stage, and Mr. Schneider demonstrated his abilities by improving the methods of operation of the plants and the handling of labor forces, including the beautification of the Company's property and the improvement of the living conditions of its operatives. This work was so notable that, in 1912, he was employed by the Amalgamated Phosphate Company, of which Mr. B. H. Brewster, Jr., was then President, and, in collaboration with Mr. Frank I. Wheeler, a Vice-President of the Company, he constructed an entirely new plant for mining phosphate on the Company's large properties at Brewster, Fla. This plant was considered for many years to be the largest and most efficient in the State and was designed so as to be the most economical in operation. Mr. Schneider continued in the operation of the plant under Mr. Brewster, and under the American Cyanamid Company, after the sale of the Brewster interests, until the climax of the labor troubles in the industry in 1919 following the World War. For a year or more, he aided the Tennessee Copper Company and its allied interests in plans for a new phosphate mining plant in Polk County, Florida, which plans, however, the Company finally decided to abandon.

In 1922, the Cities of Bartow and Lakeland, both in Polk County, received new charters and re-organized their City Governments. Bartow had long been the center of the phosphate industry in Florida and was the residence of Mr. Schneider at this time. Naturally, the municipal authorities of Bartow selected him for the new position of City Manager, but in less than a year the City of Lakeland offered him a larger field as its City Manager. The latter position he occupied for about four and one-half years during the period of the development and height of the rapid growth of so many Florida cities, from 1922 to 1928. His influence throughout these strenuous times was for the orderly advance of the city, with due attention to the economies of construction and the control of development, so that neither citizens nor city should be overloaded with debts. Complete control by any one was impossible, but the engineering and administrative skill exercised by Mr. Schneider and his associates has been evident to the many visitors, and the ability of the City Government to meet its indebtedness as it has become due, is unquestionably because of their intelligent efforts, supplemented by careful attention to the details of settlements by the Administrations following that of which Mr. Schneider was so valuable a member. During the last two or three years of his work for the City, his health was far from good, and his resignation was too long delayed, owing to his strong sense of duty. He lingered a few months and died at his home in Lakeland, on November 28, 1929.

The record of Anton Schneider, the man, is even more remarkable than that of the engineer. This may be illustrated by his treatment of difficulties connected with the performance of his technical duties. Perhaps the most outstanding of these were his acts and his attitude with reference to the labor troubles in the phosphate field immediately following the World War. A large share of the market for phosphate rock was in countries allied with Germany and, consequently, the business of the companies was very dull during and immediately after the war. When the cost of living increased, most of the phosphate companies were not in a position to increase wages without lowering dividends or suffering deficits. The Brewster Plant, as designed and operated by Mr. Schneider, was able to operate at a profit, even in those troublous times, and he could increase wages and operate in the face of strikes elsewhere, a result which was satisfactory to his own Company, but very unsatisfactory to others in the field.

Although he entered the contest subscribing to the views on the treatment of labor held by the other operators in the phosphate field, he studied the questions so thoroughly that he was converted to the view that economy of operation depended on the status of the employees. Unfortunately, the Eastern owners of most of the phosphate properties could not accept this view, partly because they were not able to operate their less ably designed properties in competition; consequently, pressure was brought to bear on the Eastern owners of the Brewster Plant which forced them to accept the common view and withdraw their support from Mr. Schneider. His sympathies, as well as the larger economic view which he had attained, supported him in his straightforward and strong adherence to what he considered to be right, even up to the point of causing his discharge. Expressions from several sources are to the effect that men familiar with the phosphate business, but not engaged in fighting the labor strikes, believed that he handled the situation for the best interests of his Company and was running his mines and works smoothly when others operated under great difficulties or shut down. His reputation as the best of plant designers and operators was well established by the results obtained until the severance of his connection with the field.

The handling of the difficult situations which arose during his term as City Manager of Lakeland also illustrated his tenacious adherence to what he considered just and right and his ability to devote himself to the solution of the larger problems, making his subordinates responsible for the development of the details. He had the ability to choose capable men, and he held the engineer's logical belief that they could and should do their best work if made responsible for the results. At times, the demands of those who were over-developing the city were too strong for the Commissioners to resist, but they accepted the responsibility for the consequent errors in policy and in technical matters which resulted.

The love of the arts—graphic, literary, and musical—was a dominant characteristic of Mr. Schneider's mind. His friends of early and middle life would feel that his story was incomplete if it did not emphasize, not only his appreciation of music, but the way in which he expressed it in performance, particularly of the works of Bach, Beethoven, and Brahms, to which he restricted himself as the years went on. His work in painting was also very creditable.

A few selections from many full expressions of appreciation of Mr. Schneider's qualities will show that his character and ability were recognized even by those who at times were opposed to his interests:

"Mr. Schneider was always cheerful, hopeful and enthusiastic in his work, of marked ability and thoroly reliable. He had a host of friends whom he was considerate enough to keep in touch with when in their vicinity."

* * * *

"He was a thoroughly competent engineer, resourceful, very energetic, and the quality of his integrity was such that he would not tolerate the slightest deviation from the truth as he saw it. * * * His personality was so strong and true that no separation can bring forgetfulness of the sympathetic understanding he gave in full measure to his friends. I knew and respected his ability as an engineer, but to me his capacity for friendship was so rare and fine a thing that I cannot write of him without trying to convey some idea of my appreciation of his personality."

* * * *

"The men who worked for him swore by him, loved him, worked over time for him, and would fight for him if necessary. Perhaps this is his best publicly known trait. He built for permanence. When Anton Schneider approached a piece of construction work he did not ask what is the cheapest way or what is the quickest way, or even what will please best. His question was what is the best known construction."

* * * *

"He searched out the strong points in individuals and stimulated them to their best efforts. He was happiest when helping in the improvement and the progress of his subordinates. I think his outstanding characteristic was his innate interest in and affection for people. * * * Mr. Schneider's frequent advice was to solve the main problem in a broad way in advance without cluttering the mind with too many details. This practice he followed. His scientific trend of mind enabled him to co-ordinate men, materials and equipment to obtain maximum results with minimum effort and waste. These qualities, together with his ability to obtain loyalty and co-operation from employes thru his sympathy and understanding, made him an exceptional executive."

* * * *

"He performed unusually difficult jobs and tackled them with a quiet concentration, carried them thru with highly original methods, and refused to talk about them or write about them. He abhorred the spectacular. When a job was finished he avoided the dedication functions and went fishing. His primary concerns in his professional tasks were a vigorously honest result and a vigorously humane treatment of the people who worked with him, down to the last laborer. While he trusted details to an astutely selected organization, he gave personal attention on his larger construction work to the living conditions, the medical care, and the recreational opportunities of his workers, skilled and unskilled, and he would not tolerate harsh treatment of any animals on the project. He showed equally to all men on his surface what he felt in his soul and he was frank and artlessly fearless. He experienced a lively satisfaction in solving the seemingly insoluble, and in meeting without a quibble his impregnable conscience concerning good workmanship. He would have revelled in the construction of medieval cathedrals, discussing stresses, form, balance, and line with the masters and apprentices; for he was blessed with an esthetic sense (oil painting was one of his hobbies) as well as an engineer's intuitive feeling of conformity with Nature and her laws and of the social service which his works rendered. Gentleness mixed with inflexible firmness, a feeling for solidity graced with line, a whimsical humor untinged with malice, an unaffected modesty modestly shown, and a sense of the reality of intangibles,—these were the attributes of soul which he brought to his work as an engineer."

At Ogden, Utah, Mr. Schneider met Mary Robinson and they were married on November 18, 1896. She survives him, together with two daughters.

Mr. Schneider was elected an Associate Member of the American Society of Civil Engineers on May 4, 1898, and a Member on July 2, 1913.

PHILIP SCHUYLER, M. Am. Soc. C. E.[1]

Died December 11, 1931

Philip Schuyler, the only son of the late Howard Schuyler, M. Am. Soc. C. E., and Frances (Brannon) Schuyler, was born in the City of Mexico, Mexico, on July 3, 1880. In him was the blood of pioneers on both the paternal and maternal sides. On his mother's side he was the grandson of Samuel Brannon, who came to California in 1846 and who was known as the "First Forty-Niner." His father, who traced descent from General Philip John Schuyler, of Revolutionary fame, was one of America's great railroad engineers; he located the Kansas Pacific and the Denver and Rio Grande Railroads, building the latter, as well as the Northwestern Pacific Railroad, out of San Francisco, Calif., and was Chief Engineer of the Mexican Central Railroad during its construction. Philip Schuyler also was the nephew of the late James Dix Schuyler, M. Am. Soc. C. E., one of the West's great hydraulic engineers.

His early childhood was spent in France and Switzerland, but after his father's death his mother returned with him to America, and Philip was placed in Trinity (Episcopal) School, in New York, N. Y., preparatory to entrance to Cornell University. It was necessary for him to leave Cornell in his Sophomore year (1899), at the age of 18, to assume the support of his mother.

Inherited instinct brought him to California, and, with the exception of two years in Western Nebraska and at Monterrey, N. L., Mexico, this State was the scene of his life work. His first jobs, from 1899 to 1902, were, successively, Rodman, Instrumentman, Draftsman, Engineer in Charge of Field Parties, and Inspector of Hydraulic Mines, for the California Débris Commission (United States Engineer Corps).

From 1902 to 1904, Mr. Schuyler was Engineer in Charge of Surveys for Mr. W. P. Hammon, at Oroville and Marysville, Calif., on gold-dredging operations. The years, 1904 and 1905, he spent partly in the employ of his uncle, Mr. James Dix Schuyler, and partly as City Engineer of Venice and Ocean Park, in Los Angeles County.

---

[1] Memoir prepared by Harold F. Gray and Clyde C. Kennedy, Members, Am. Soc. C. E.

Then followed his only professional excursions outside of his adopted State. In 1905 and 1906, he was Assistant Engineer with the Tri-State Land Company, at Scottsbluff, Nebr., on canal location and plane-table topography. In 1906 and 1907, he was Assistant Engineer in charge of construction of the water-works, and part of the time on supervision of the sewerage system, at Monterrey, N. L., Mexico, for the Monterrey Water-Works and Sewer Company, Limited.

He returned to California in 1907, and until 1912 was associated with Stephen E. Kieffer, M. Am. Soc. C. E., on subdivisions, sewers, water-works, and irrigation in various parts of the State.

In 1912 Mr. Schuyler entered the contracting field, constructing, among many other projects, the water supply system for the Panama-Pacific International Exposition, in San Francisco, and 8½ miles of heavy canal construction for the Orland (Calif.) Project, United States Reclamation Service.

In 1918 and 1919, he was Assistant Engineer, United States Housing Corporation, on the design and construction of paving, water and sewers, gas, street and house lighting, and pumping plant and reservoir, at the Mare Island Navy Yard, near Vallejo, Calif.

From 1919 to 1925, Mr. Schuyler was engaged in sales engineering work, in the promotion of sales of valves, water softeners, and vitrified pipe, being associated with the Coffin Valve Company, International Filter Company, Gladding McBean Company, and several others. In these years he made the contacts with engineers and contractors around which grew the rich friendships which were his most prized possessions during the remainder of his life.

This varied experience, supplemented by the extensive reading of an inquiring mind of broad interests, was preparing him for his real field of usefulness and achievement, and, in 1925, he became the first Managing Editor of *Western Construction News,* of San Francisco. He able editorship rapidly built up the new venture to a pre-eminent position in its field on the Pacific Coast, serving both engineer and contractor in the Far West.

Philip Schuyler was imbued with lofty, yet practical, idealism, and his magazine was dedicated to the cause of conservation of the West. He gave to *Western Construction News* its slogan "Keep the Far West Clean." Having always an especially keen interest in the public health relations of engineering, he labored and inspired others to labor toward the reduction of stream and bay pollution. He believed that civilization, through carelessness or neglect, should not destroy its natural resources, or defile its recreational areas.

He gave his time and strength unsparingly to the work of organizations which contributed to the engineering betterment of the West, holding membership in the American Water Works Association, the California Sewage Works Association, the Electrical Development League, of San Francisco, the Engineers' Club, of San Francisco, and the East Bay Engineers' Club, of Oakland, Calif. He was also a member of the Society of California Pioneers, the Demi-Tasse Club, of San Francisco, and the Oak Knoll Country Club, of Oakland.

There was no mean thing in the character of Philip Schuyler. Born a gentleman, he lived his life true to the instincts of a gentleman. Whatever he did, he did with enthusiasm, and he engendered enthusiasm in those associated with him. He dealt with men with courtesy and an instinctive consideration of their feelings, and he bred courtesy and high regard in return. He had a deep, friendly interest in every one he knew, and he numbered his friends by the hundreds.

In a memorial on the occasion of his death, the East Bay Engineers' Club characterized him, as follows:

> "Exponent of high ideals of professional conduct; keenly interested in the progress of engineers and engineering; a strong contender for the right; acute in understanding of men and principles; warm-hearted, kindly and courteous; friendly to all and beloved by his friends; he was an ornament to the profession of engineering, and exemplified in the highest degree the attributes of a scholar and a gentleman."

In January, 1931, Mr. Schuyler was stricken with influenza, with finally fatal sequelæ, but true to his ideals of service, he refused to rest. Throughout his long illness, he never faltered nor lost courage.

He was married on April 16, 1912, to Cecily Ann McLaughlin, at San José, Calif., who, with his daughter, Barbara Anne, survives him.

Mr. Schuyler was elected an Affiliate of the American Society of Civil Engineers on December 15, 1924, and a Member on October 1, 1926.

MITSUGU SENGOKU, M. Am. Soc. C. E.[1]

Died October 30, 1931

Mitsugu Sengoku, the second son of Yajima Sengoku, a Samurai of the Kochi Clan, was born on June 2, 1857, at the Town of Kochi, Shikoku Island, Japan. He received his early education in his native town and, at the age of 16, he went to Tokyo, and under the guidance of the late Count Shojiro Goto, a prominent pioneer statesman and builder of the New Japan, who had come from the same clan, he entered the Science Department of the University of Tokyo, to study Civil Engineering, which course he finished in July, 1878.

Upon his graduation from the University Mr. Sengoku entered the service of the Local Government of Tokyo, where he was employed in the Civil Engineering Department, starting thus in his career as an engineer. After three years, however, he gave up this position and joined the North-Eastern Railway Company. In February, 1884, he entered the Government Railway Service, being appointed an Engineer of the Tokyo Bureau of Railways, then under the control of the Public Works Department. In December of the same year, when, at the request of the Nippon Railway Company, the Department undertook the construction work of that Company, Mr. Sengoku was ordered to take charge of the construction of the Nakata-Utsunomiya Section and, later, in September, 1885, that of the Shirakawa-Fukushima Section, both of which he accomplished successfully. In January, 1888, he was put in charge of the construction of the Shinjuku-Tachikawa Section, which now forms an important part of the Central Line, with its noted straight route extending more than 35 km. (about 22 miles). In June, 1888, he was ordered to go abroad to study railways, and was absent for 1½ years. During that trip he visited the Hartz Railway, in Germany, designed by Roman Abt, and, upon observing a mountain railway with a gradient of 16.2%, operated by a combined track of rack and ordinary rails, he submitted a report of what he had seen, and, as a result, it was decided to use the Abt System for the Yokokawa-Karuizawa Section, the present route of the Usui Pass (noted for its steep gradient) being selected.

---

[1] Memoir prepared by Mr. Shuzo Aoki, Tokyo, Japan.

In 1889, the street improvement of Tokyo was mapped out on a gigantic scale, the construction of an elevated urban line connecting Shimbashi Station with that of Ueno being included in the plan. Accordingly, in September, 1890, the Home Minister of the Imperial Government instructed the Director of the Railway Board to begin the construction work of this route, together with a large central station within the city limits. In this connection, Mr. Sengoku was appointed to direct operations and discharged his duty with his usual diligence.

In May, 1890, he was promoted to the rank of Railway Engineer of the Third Grade and in August, 1891, the title of Doctor of Science in Engineering was conferred upon him by the Japanese Government. In July, 1892, the Government Railways of Japan appointed a Committee of fifteen to make investigations and map out the best possible network of railways to be built in Japan. Dr. Sengoku was appointed a member of the Committee, and his advice proved invaluable. While acting as an Adviser, he was also made Supervisor of Surveying and Railway Construction, and the three Government Lines, the San-in, the Maizuru, and the Wakayama were surveyed under his supervision. At the time of the Sino-Japanese War (1894–1895), he was instructed to proceed to Korea on a mission entrusted him by the War Department and visited Fusan, Seoul, Chemulpo, etc., in the course of his trip. In November, 1895, after the close of the war, he was decorated by the Emperor with the Minor Cordon of the Rising Sun of the Fourth Grade, as well as a War Medal, in recognition of his services rendered during the war.

The next position, to which he was appointed in September, 1896, was that of Chief Engineer of Railways at that time under the control of the Minister of Communications. It was in this period of his life that the question of converting the gauge of the Government Railways from narrow to standard gave rise to a heated discussion in Japan. Accordingly, the Minister of Communications organized a committee to investigate the matter, instructing its members to inquire thoroughly into the question of gauge widths, expenditure involved, etc. Dr. Sengoku was included in the Committee, and, on his appointment, he made his opinion public in a pamphlet bearing the title "My Idea for Standardization of the Gauge", in which he vehemently advocated the necessity of reform. Notwithstanding his strong opinion, however, his attempt failed to obtain general support from other quarters, and the question was dropped, although it has since been repeatedly discussed both by the authorities and the politicians. In August, 1911, and again a few years later, another organization for the realization of the plan was created, and it was earnestly discussed; in each case Dr. Sengoku was appointed a member of the Committee. Especially in the latter case, when Dr. Sengoku was President of the Railway Board, a lengthy research was conducted extending over one and one-half years, and the standardization program became generally favored, but it was once again abruptly discarded, owing to his resignation and other financial difficulties, and the gauge has remained unchanged as it is to-day.

In October, 1896, Dr. Sengoku retired from the Government Service, in order to enter upon a business career, in which he achieved also a signal success. The first position he held was that of the Presidency of the Chikuho Railway Company to which he was elected in November, 1896. In August, 1896, while acting as President of the Company, he had been commissioned by the Government to organize the Imperial Iron Works, in Kyushu. In April, 1897, when the Chikuho Railway Company was amalgamated with the Kyushu Railway Company, he was named Vice-President and Managing Director of the latter Company until April, 1898, when he was elected President and Managing Director. Later, this Company amalgamated more railway companies in Kyushu, such as the Imari, the Hoshu, and, the Karatsu Railway Companies, under his Presidency. This position Dr. Sengoku held for ten years until July 1, 1907, when the railway was purchased and made over to the State Railways of Japan at a price of 118 850 000 yen. During his term as President the Russo-Japanese War broke out, and with the transportation of soldiers and provisions, the capacity of the railway was taxed to its fullest extent, but as President Dr. Sengoku was equal to the occasion. After the war, in April, 1906, in recognition of his service, the Third-Class Order of the Sacred Treasure was conferred upon him by the Emperor.

The first problem that presented itself in the wake of the war was how to turn to account the newly acquired rights in South Manchuria which had come under Japan's control by the Portsmouth Treaty concluded in 1905. Manchuria, in those early days, was nothing but a mere wilderness extending for hundreds of miles, uninhabited by any people, and, in order to develop its abundant natural resources, a better management of the railway ceded by Russia was judged indispensable. The Imperial Government thereupon appointed a committee to make the necessary investigations regarding its organization. Dr. Sengoku was summoned once again by the Government and was included in the Committee. His untiring efforts in conjunction with those of the Government resulted, toward the end of 1906, in the firm establishment of what is now known as the South Manchuria Railway Company.

With respect to his political career, Dr. Sengoku was elected to the Diet as a representative of his native town, Kochi, in May, 1908, having subsequently been returned three times in succession from the same constituency. He joined the ranks of the Kenseikai, or Constitutional Party, with Count

Kato at its head, and was reckoned as one of the most powerful members, feared and respected by his colleagues. About 1909, he became an Adviser of the Japan Nitrogen Fertilizer Company, a pioneer company that made a great success in the production of fertilizer and contributed much toward its improvement as used in Japan. In October, 1911, he became connected with the Inawashiro Hydro-Electric Company, a pioneer company that succeeded in effecting an epoch-making, long-distance transmission of a current of 100 000 volts.

Dr. Sengoku was not allowed to enjoy his calm private life for long, and, in April, 1914, he was recalled once again to the Government Service and appointed President of the Imperial Railway Board, which was later re-organized into the Department of Railways. While in this position, he established what was called the seven years' program of railway construction and improvement, practically fixing thereby the railway policy of Japan. On the occasion of the Imperial Enthronement that took place during his Presidency, in April, 1915, he was appointed a Councillor in connection with the Enthronement function and discharged his duties most successfully.

In January, 1921, he became the President of the Civil Engineering Society of Japan, for a term of one year.

In July, 1924, Dr. Sengoku was appointed Minister of Railways. Some of the principal innovations effected during his administration comprised a plan for establishing a hydro-electric power station on the River Shinano and a steam power station in the neighborhood of Tokyo. These plans were intended to materialize the long-cherished policy of the Government Railways, that is, to be self-supporting as regards power. The gigantic work of replacing the old couplers on the entire rolling stock on the Government Railway System with automatic couplers, that was effected in the course of a few days in July, 1925 (an incident unprecedented in railway history) was another service rendered by him during his administration.

In 1925, Dr. Sengoku was appointed a permanent member of the House of Peers by the Imperial Order, but in June, 1926, when he was relieved of his post as Minister of Railways, he resigned his membership in the House of Peers, at the same time withdrawing himself from the Minseito Party, thereby withdrawing from political life.

In January, 1926, after the World War, he was decorated with the First Class Order of the Sacred Treasure, on account of his services rendered during the war.

The position that eventually proved his final service for the State was that of the Presidency of the South Manchuria Railway Company, of which he had once been a promoter. This position he held for 1 year and 10 months, but during his Presidency, he encountered difficult management problems, owing to the financial depression throughout the world as well as the slump in the price of silver. Notwithstanding the general unfavorable situation, he was indefatigably striving to improve it when he was suddenly taken ill in February, 1931, on his way from Dairen, in Manchuria, to Tokyo, and, after a protracted illness, he died on October 30, 1931, at his villa in Katase, near Kamakura.

Dr. Sengoku possessed a somewhat unusual character in that he was extremely open-hearted, straightforward, and bold. In writing of him, Mr. Tsunego Baba, one of the most popular critics of present-day Japan, says:

> "While Mr. Sengoku was open-hearted, intrepid and even passionate in his rage, thus earning him his nickname 'Thunder', it must be remembered that he was also a man of genial, kindly nature, always ready to help others at the expense of his own interest. As such he was always loved and respected by all who knew him."

Dr. Sengoku's kindness might be illustrated by an incident that took place a few weeks before his death. For a long time he had cherished the hope of erecting a bronze statue in honor of the late lamented Cornelius Johannes Van Doorn, a Dutch engineer, who had done much in the cause of civil and hydraulic engineering work in Japan, but through some hindrance or other, he had long been unable to realize it. His untiring efforts, however, were crowned at last with success, and through the activity of the Tokyo Electric Company, and others, a statue in memory of the deceased engineer was at length erected on the shore of Lake Inawashiro and unveiled sixteen days prior to Dr. Sengoku's death.

As regards diversions, golf and the Japanese game of "go" were two pastimes in which he took much interest. Upon his death he was decorated by the Emperor with the First Class Grand Cordon of the Rising Sun, and his court rank was promoted to that of the Junior Third Class. Again, on the occasion of the funeral service, His Majesty, the Emperor, was pleased to grant a considerable sum of money toward the funeral expenses.

Dr. Sengoku was elected a Member of the American Society of Civil Engineers on June 4, 1890.

ROBERT AMES SHAILER, M. Am. Soc. C. E.[1]

Died July 7, 1930

Robert Ames Shailer was born in Roxbury, Mass., on July 27, 1852, the son of the Rev. Julius S. Shailer and Catherine Parmelee Read Shailer, of Haddam, Deep River, Conn. The Rev. Julius S. Shailer was Principal of the Suffield Literary Institution and Pastor of the Ruggles Street Baptist Church, of Roxbury.

Robert Ames Shailer was graduated from the Boston Latin High School and, subsequently, from the Massachusetts Institute of Technology in the Class of 1873.

Among the following are listed the various positions which he held after his graduation from college: 1873 to 1874, Draftsman, with the New England Iron Company; 1874 to 1875, Transitman for the Lawrence (Mass.) Water-Works; 1875 to 1878, Assistant Engineer for the American Bridge Company; 1876 to 1878, Resident Engineer on construction of foundations for the Poughkeepsie Cantilever Bridge over the Hudson River; 1878 to 1879,

---

[1] Memoir prepared by George H. Pegram, Past-President, Am. Soc. C. E., and George Perrine, M. Am. Soc. C. E.

Assistant Engineer, United States Engineers, in charge of an hydraulic survey of the Charles River, Massachusetts; 1879, Assistant Engineer with the late C. Shailer Smith, M. Am. Soc. C. E., Consulting Engineer, at St. Louis, Mo., and later in the same year, Assistant Engineer, the Edgemoor Iron Company. He was also employed from 1885 to 1890 by Rush and Coolidge, Chicago, Ill.

When Mr. Shailer was elected a Member of the Engineers Club in New York, N. Y., in 1906, the following additional professional record was supplied: Assistant Superintendent of the Edgemoor Iron Company; Engineer of Bridges and Buildings for the Chicago, Milwaukee and St. Paul Railroad Company; President of the firm of Shailer and Schniglau Corporation, Engineers and Contractors, of Chicago; President of the Boston, Mass., Tunnel Construction Company; and, later, Chief Engineer of the Degnon Contracting Corporation, in New York, during the construction of the Steinway Tunnel under the East River.

The Shailer and Schniglau Corporation constructed, during 1893 and 1896, one mile of the Chicago Drainage Canal and the Lake View Tunnel, two miles of which were under Lake Michigan, including the intake in the lake, and one mile of Hyde Park Tunnel; the two latter works were for the water supply of the City of Chicago. This firm also built the Scollay Square Section and the Haymarket Square Section of the Boston Subway. The Boston Tunnel Construction Company of which Mr. Shailer was President constructed a double-track concrete-lined tunnel, 5 000 ft. long, under Boston Harbor. Secretary of Commerce B. P. Lamont was Secretary and Engineer with the Shailer and Schniglau Corporation.

The contracting firm of Shailer and McCormick built the pneumatic foundations for the Newburyport, Mass., Bridge over the Merrimac River and, later, constructed a reinforced concrete viaduct at Jacksonville, Fla., over the tracks of the four railroads entering that city.

Mr. Shailer was also Managing Engineer for the T. A. Gillespie Company, General Contractors, on the construction of the Rondout Siphon of the Catskill Aqueduct, which supplies water to New York City.

Subsequently, he was Consulting Engineer for the General Contractors on the construction of the Cambridge Subway and the Beacon Hill Tunnel of the Boston Elevated Railway System. From 1915 to 1919, he served as Tunnel Engineer for the Rapid Transit Subway Construction Company, during the completion of the Queensboro Tunnel, originally the Steinway Tunnel, starting at 42d Street and Park Avenue, New York City, passing under the East River, and terminating in Long Island City. This tunnel was originally designed for the use of trolley cars, but, later, was changed to a third-rail system, and in 1913 was made part of the Interborough Rapid Transit System. This work was completed in conjunction with what was commonly called the "Diagonal Station" at 42d Street, and which has since become the Grand Central Station of the Interborough Lines.[2]

Mr. Shailer possessed an attractive personality, a keen mind, and a fund of energy, and was endowed with what might be termed a natural accuracy and directness. These qualities contributed largely to his unusual ability as an executive, and as an adviser. His statements even in ordinary conversation were clean-cut and definite, without loquacious or humorous "trimmings".

---

[2] *Transactions*, Am. Soc. C. E., Vol. LXXXII (1918), p. 327.

He was very fond of fishing and hunting—in fact, he might be called an expert in these sports, in which he was active until very near the end of his life, and, aside from his friendly manner, his stories of exploits made him a charming companion. He had a host of friends and could generally be found among a group of them in his leisure moments. He was a Thirty-second Degree Mason.

To his engineering brethren and the contractors with whom he was associated, he was frank and free in stating his experiences and helping them to solve doubtful problems. In short, he was a man whose demise is a notable loss to the Engineering Profession and a great bereavement to his many friends.

On May 31, 1877, Mr. Shailer was married to Grace Ellen Hooper, the daughter of Frederick T. Hooper and Louise (Stetson) Hooper, of Boston, Mass. Their family consisted of five daughters and one son, of whom three daughters, Mrs. Alfred C. Turner, Mrs. Wilson C. Handyside, and Mrs. Paul F. Avery, and the son, Harold Read Shailer, survive him.

Mr. Shailer was elected a Member of the American Society of Civil Engineers on March 3, 1880.

WILLIS APPLEFORD SLATER, M. Am. Soc. C. E.[1]

Died October 5, 1931

Willis Appleford Slater was born in the small town of Polo, Ill., on October 14, 1878, and received his early education in the country schools and High School of that community. Both his father, Belford Slater, and his mother, Ruth (Appleford) Slater, were of English descent, the first of his line having settled in Lynn, Mass., in 1684. The value of advanced knowledge and the discipline of work were thoroughly instilled in the boy, and formed the very apparent and sound foundation of his later achievements and reputation.

Willis Slater was graduated from High School at the normal age of sixteen, but from that time he alternated periods of gainful employment with those of further schooling. Three years after leaving High School he was able to attend Valparaiso University, at Valparaiso, Ind., for two years. After two more years, he entered the University of Illinois at Urbana, Ill., as an engineering freshman, and was graduated with his class in 1906, at the age of twenty-seven, with the degree of Bachelor of Science in Municipal and Sanitary Engineering..

Field experience as Axeman, Rodman, Leveler, and Chief of Party followed in 1906 and 1907, taking Mr. Slater eventually to Elgin, Ill., where he met and loved Clara Mary Knodle, whom he married on June 3, 1908.

---

[1] Memoir prepared by Arthur R. Lord and Franklin R. McMillan, Members, Am. Soc. C. E.

Meanwhile, he had moved on to Ely City, and McGill, Nev., and to Salt Lake City, Utah, working as Draftsman and Designer on municipal and structural projects. In the fall of 1908, he was appointed Research Fellow in the Engineering Experiment Station, and returned to the University of Illinois with his bride of three months. By this time he had determined to specialize in reinforced concrete, and here began, under the guidance of Arthur N. Talbot, Past-President and Hon. M. Am. Soc. C. E., the program of research in structural engineering that was to engage Professor Slater for the remainder of his life. Here was born his only child, Ruth Marjorie Slater, now a student in the University. At this time Willis Slater was a mature man of thirty, and his work attracted favorable attention at once. After receiving his degree of Master of Science in Theoretical and Applied Mechanics in 1910, he was retained at the University as First Assistant in the Engineering Experiment Station from 1910 to 1915, and as Research Assistant Professor from 1915 to 1917. His professional degree of Civil Engineer was awarded in 1912, in recognition of distinguished technical research already completed.

At this period began the extensive output of technical papers and bulletins on which his fame particularly rests. While still a Research Fellow, he became a member of the American Concrete Institute and of the American Society for Testing Materials and contributed to their proceedings and conventions. Research for Professor Slater meant the most careful preparation for the test program, with a full consideration of all available data in the same general field. His specimens were designed, his readings taken, so as to secure significant data only. Complicating variables were foreseen and controlled as necessary. With his data secured, there followed a long-period of exhaustive study and analysis. Often additional tests were conducted to clear some doubtful point. Very commonly his analysis included the derivation of new mathematical formulas for the use of others in further investigation, or as a basis for design. Publication was always complete, with his data, analyses, and conclusions fully stated and most carefully and conservatively worded. The published papers of Professor Slater, as a result, commanded the respect and confidence of the Structural Engineering Profession by their uniformly high quality, and their practical usefulness.

The services of Professor Slater came greatly into demand for research undertakings away from the campus. He was employed as Consulting Engineer to conduct extensive investigations into the properties of gypsum and to establish standards for structural design in that material. Later standardization by the American Society for Testing Materials was largely founded on this work. With Professor Talbot he was closely connected with the early tests for actual stresses in reinforced concrete buildings, and they were joint authors of two *Bulletins*[2] on this subject. With H. M. Westergaard, M. Am. Soc. C. E., he prepared a paper, "Moments and Stresses in Slabs," which was first published by the American Concrete Institute,[3] and almost immediately reprinted by the National Research Council.

---

[2] "Tests of Reinforced Concrete Buildings Under Load," by Arthur N. Talbot and W. A. Slater, *Bulletin No. 64*, Univ. of Illinois Eng. Exper. Station; and "Tests of Reinforced Concrete Flat Slab Structures," by Arthur N. Talbot and W. A. Slater, *Bulletin No. 84*, Univ. of Illinois Eng. Exper. Station.

[3] *Proceedings*, Am. Concrete Inst., Vol. XVII (1921), p. 415.

With the entrance of the United States into the World War and the suggestion that ships be built of concrete in the emergency, Professor Slater was called to the Bureau of Standards, in Washington, D. C., and there made the preliminary study to determine the feasibility of such construction. A lack of adequate design data was discovered and a tremendous research program was instituted under Professor Slater's direction, on the results of which the design of concrete ships and barges was founded. While these tests were planned for this particular use, the data thus secured proved to be exceedingly valuable for the design of all types of reinforced concrete structures. Professor Slater's paper[4] before the American Concrete Institute in 1919, in which these data were summarized, was awarded the Wason Medal of the Institute.

These exhaustive data, still incompletely studied and analyzed, passed to the Bureau of Standards at the close of the war, where, through Professor Slater's further study, they formed the basis of several important *Bulletins,* applying the results to peace-time uses. Professor Slater remained at the Bureau from 1919 to 1928, becoming Chief of the Section of Masonry Structures. During these years he was frequently "borrowed" in order that he might direct some outside research project. Tests of clay-tile-and-concrete-joist construction in Ohio laid the solid foundation on which such construction is now universally designed. Most notable of all, however, was the Arch Dam Investigation of Engineering Foundation, which took Professor Slater to California for two years, from 1925 to 1927, and demanded the highest skill both in experimental technique and in mathematical analysis. During 1923 and 1924 he was happy to be able to serve his Alma Mater for sixteen months, supervising the concrete construction of the Illinois Memorial Stadium. During this period, also, he was honored by appointment of the American Society of Civil Engineers as Chairman of its representation on the Joint Committee for Specifications for Concrete and Reinforced Concrete.

In 1928, Professor Slater was appointed Research Professor of Engineering Materials and Director of the Fritz Engineering Laboratory at Lehigh University, Bethlehem, Pa. In this strategical position he was rapidly building up the research facilities and reputation of that laboratory. An outstanding investigation under way there was the fundamental column research of the American Concrete Institute (divided equally between Lehigh University and the University of Illinois), conducted by a committee of which Professor Slater was Chairman. Most of the testing had been completed and highly significant results already obtained at the time of his death. Two progress reports had been published, and the third and fourth reports were in preparation, when he was taken, in his fifty-third year, at the height of his power and usefulness.

Professor Slater had always so many things of overwhelming interest to himself, of so much importance to others, to attend to immediately, that he continually overtaxed his strength. He was not only a member, but was decidedly active in both administrative and technical committee work in many technical and scientific societies. He was a member of the American Society for Testing Materials, American Concrete Institute, Concrete Institute (British), American Association for the Advancement of Science, Washington Academy of Sciences, and the American Welding Society. He was Chairman of the present National Joint Committee on Specifications for Concrete and Reinforced Concrete. Only in recent years did he come to realize that he must give up some of the older obligations when he accepted the new and greater responsibilities that were continually seeking him out. While still at the University of Illinois he was subject to severe and prolonged headaches and these, later, became almost daily in occurrence. He worked steadily on. While in recent years this trouble had moderated somewhat, it was never completely overcome by medical care. The two years in California, on the Arch Dam Test at Stevenson Creek, built him up wonderfully, but the cumulative effect of long years of over-strain was apparent in the complications that followed suddenly upon an attack of tonsilitis and rendered it fatal.

---

[4] "Structural Laboratory Investigations in Reinforced Concrete, Made by Concrete Ship Section, Emergency Fleet Corporation," *Proceedings,* Am. Concrete Inst., Vol. XV (1919), p. 24.

Perhaps the best measure of Professor Slater's personality was the number and intimacy of his immediate friendships. His personal charm, his intellectual integrity, his unquestioned impartiality and fairness, and his rare patience won every one who became closely associated with him in professional work or engineering society activities. And these friendships were of the enduring kind; to know him better was to love him more. In the quality of his friendships, no less than in the thoroughness of his researches, he leaves a record in which any man could take pride. At conventions he was ever surrounded by a group of those who had come to know the pleasure it gave him to assist others, out of his great fund of knowledge and experience. He was fond of hearing and of telling stories—invariably clean stories—and was given to relieving the intensity of committee meetings by a keen humorous remark. He constantly encouraged younger research workers, and shared authorship with his assistants generously. Of him, as of the "Home on the Range," it could be said that:

"There seldom was heard
A discouraging word,
And the skies were not cloudy all day."

Professor Slater was elected an Associate Member of the American Society of Civil Engineers on June 24, 1914, and a Member on January 22, 1922.

JAY L. STANNARD, M. Am. Soc. C. E.[1]

DIED MARCH 13, 1931

Jay L. Stannard was born on September 15, 1866, at Chittenango, N. Y., the son of Gilbert and Esther (Heberd) Stannard. His father, a farmer, soon moved to Iowa where the boy attended the public school at Shell Rock, and received a two years' training at Cornell College, Mt. Vernon.

---

[1] Memoir prepared by R. K. Tiffany, M. Am. Soc. C. E.

At the age of 21 years, on being offered a position as Rodman on the Chicago, St. Paul, and Kansas City Railroad (now the Chicago Great Western Railroad), Mr. Stannard was attracted from the halls of learning to the active life of construction work, which he followed thereafter until his death. Many years of his young manhood were spent in railroad construction, which branch of the profession he followed in Iowa, Idaho, Washington, Pennsylvania, and Montana. For two years, beginning in 1890, he was employed on the Staff of the City Engineer of Whatcom (now Bellingham), Wash., and from that time his interest turned largely to water supply and power problems. For several years he was employed by the California Red Wood Pipe Company and the National Wood Pipe Company in charge of many large pipe installations.

From January, 1907, to January, 1910, Mr. Stannard served as Assistant City Engineer of Seattle, Wash., in charge of the construction of the second unit of the Cedar River Water Supply and the second unit of the Seattle Municipal Power Plant. Following 1910, for several years, he was engaged in private engineering practice, designing and building water supply and power systems for many cities in Oregon and Washington. In 1923, the City Commission of Tacoma, Wash., in anticipation of the building of a large hydro-electric project, employed Mr. Stannard as Chief Engineer. After a few years, impressed by the soundness of his judgment, not only in engineering, but in the business and economic phases of the city's development program, the Commission made him Chief Engineer of Public Utilities, which position he held at the time of his death.

The Cushman Power Project of the City of Tacoma will long stand as a material monument to Jay Stannard—"The Chief," as he was affectionately known by the "men on the job". To him is due the credit for the revision of the original project plans which resulted in the highest economical development of the project, and for the bringing together of a smooth working organization which, under his direction, fashioned those plans into reality.

To his friends, associates, and employees, Mr. Stannard's life was a constant inspiration and incentive to put forth their best efforts on the work at hand. His memory will live in their hearts not only because of his engineering genius, although he had the quick, keen mind that characterizes the great engineer, nor yet because of his sound judgment on business and financial matters, although in that field lay, perhaps his greatest value to those he served; but rather on account of his more personal qualities—the kindliness, the gentle dignity, the friendly humor, the sturdy honesty that flowed through his every action. He was one of those rare men of whom it may be truly said: "None knew thee but to love thee, nor named thee but to praise."

Mr. Stannard was married in 1902 at Waterloo, Iowa, to Carrie A. Nettleton, who survives him.

He was the leading spirit in the organization of the Tacoma Section of the Society and became its first President in January, 1930. He was unanimously re-elected for a second term, and his trip South, while undertaken chiefly for a rest and recuperation after the long and strenuous Cushman Project construction period, was planned with the intent of calling on the various California and Oregon Sections and extending to them in person a cordial invitation to attend the Annual Convention of the Society in Tacoma on July 8 to 11, 1931.

The Tacoma Section, on April 13, 1931, unanimously passed the following resolution and ordered that it be engrossed on parchment, signed by the members of the Section, and bound in leather for presentation to Mrs. Stannard:

> "*Whereas,* Jay L. Stannard, a beloved fellow engineer, having achieved works of outstanding merit, has been called to his reward by an All Wise and Loving Heavenly Father;
>
> "*Whereas,* the engineering profession has been uplifted by his faithful service and our community has been enriched by the ample fruits of his zeal, proficiency, and wisdom; and
>
> "*Whereas,* His professional associates mourn his loss and in so doing keenly realize that Mrs. Stannard has sustained a still greater loss; therefore be it
>
> "*Resolved,* That we bow to the Divine Will, with a spirit of thankfulness for the inspiration and enthusiasm gained by association with our lately departed brother;
>
> "*Resolved,* That we express our deep appreciation of his professional integrity, his loyalty to friends, his upright and noble ideals, and his earnest efforts in behalf of the Section; and
>
> "*Resolved,* That the heartfelt sympathy of this Section be extended to Mrs. Stannard and other members of the family."

Mr. Stannard was elected a Member of the American Society of Civil Engineers on August 31, 1915.

EUGENE WASHINGTON STERN, M. Am. Soc. C. E.[1]

DIED NOVEMBER 9, 1931

Eugene Washington Stern was born at Toronto, Ont., Canada, on August 20, 1865, the son of Samuel and Alice (Block) Stern. His father fought under Kossuth in the Hungarian War of Liberalism in 1848, before coming to America.

Mr. Stern obtained his engineering education at the School of Practical Science of the University of Toronto, from which he was graduated in 1884. From August to November, 1884, he was Rodman on the Northern and Pacific Junction Railway, and from November, 1884, to November, 1885, Assistant Engineer on the same road, in charge of the construction of twelve miles of line. From November, 1885, to May, 1886, he was Fellow of Engineering in the School of Practical Science of the University of Toronto, in charge of drafting and the field work in surveying, also lecturing on descriptive geometry.

From August, 1886, to March, 1887, Mr. Stern was with the Passaic Rolling Mill Company, at Paterson, N. J., working on the shop plans of railway and highway bridges, including those of the Washington Arch Bridge over the Harlem River, in New York, N. Y. From March to September, 1887, he was an Assistant Engineer on the construction of the Grand Avenue Cable Railway, at Kansas City, Mo., and from September, 1887, to February, 1892, he was employed by the Chicago Bridge and Iron Company, first as Draftsman and, later, as Assistant Engineer on the design of highway and railway bridges, roofs, and substructures. From February, 1892, to 1897, he was with the Koken Iron Works, at St. Louis, Mo., as Engineer in responsible charge of the design and construction of structural iron work for buildings, roofs, bridges, water towers, etc.

---

[1] Memoir prepared by Henry Goldmark, M. Am. Soc. C. E.

In 1898, Mr. Stern came to New York City where he made his home during the remainder of his life. He was Chief Engineer of the Jackson Iron Works for about three years, and then established an office as Consulting Engineer, specializing in structural steel work for buildings, etc. In 1915, he received the appointment as Chief Engineer of the Bureau of Highways in the Borough of Manhattan, and continued in this position until 1917, when he entered the military service of the United States. He served in the World War as a Major of Engineers in the Officers' Reserve Corps of the American Expeditionary Forces. He was with the Eighth French Army, Toul Sector, from November, 1917, to December, 1918. Later, he became Chief Road Officer of Base Section No. 2, and was recommended for promotion to the rank of Lieutenant-Colonel. He received his discharge on January 16, 1919

After he left the Army, Mr. Stern returned to New York City and resumed his work as Consulting Engineer, specializing in steel construction. He was associated in this work with his brother-in-law, Robert D. Kohn, Charles Butler, and Associates, Architects. As an Associate of this firm of architects, Mr. Stern was in charge of the design and construction of the engineering features of many large buildings in New York and other cities. Among the most important of these were the twenty-story additions to the Department Store of R. H. Macy and Company, at 34th Street and Broadway; the New York Evening Post Building, on Vesey Street; the Nurses Home of Mount Sinai Hospital; the new building for the Temple Emanu-El; the D. Auerbach and Sons Candy Factory, Eleventh Avenue, 46th and 47th Streets, New York City; the Namm Department Store, in Brooklyn, N. Y., etc. Among other buildings with which he was professionally connected should be mentioned, the Terminal Station of the Delaware, Lackawanna and Western Railroad, in Hoboken, N. J.; the B. Altman and Company Store, at Fifth Avenue and 34th Street, and the office building of the Guaranty Trust Company, in New York City; and the State Armory, and the Home Office Building of the Travelers Insurance Company, at Hartford, Conn.

Mr. Stern was a member of the Society of American Military Engineers, the American Legion, and the Military Order of the World War. He was also a member of the City Club and of the Society for Ethical Culture in New York, as well as the Engineering Institute of Canada, the Society of Professional Engineers of New York State, and the American Institute of Consulting Engineers. The American Institute of Consulting Engineers owed its success from its foundation largely to his unremitting efforts. He was specially interested in associations dealing with Structural Engineering, being a member and active worker in the American Concrete Institute and the Structural Engineering Society of New York State.

During an extended professional career, Mr. Stern accomplished a large amount of important engineering work. He was also much admired by all with whom he came in contact for his lovable and helpful personal character.

On February 2, 1899, Mr. Stern was married to Dorothea Kohn, of New York City, who, with two children, Helen (Mrs. Mark C. Meltzer), and Theodore, survives him.

Mr. Stern was elected a Member of the American Society of Civil Engineers on March 3, 1897.

FRANK STODDARD STEVENS, M. Am. Soc. C. E.[1]

Died May 26, 1931

Frank Stoddard Stevens, the son of Noah Miller and Martha Ann (Shute) Stevens, was born at Athens, Pa., on December 7, 1850. His maternal grandmother, Hannah Stoddard, a direct descendant of William the Conqueror, was born in Minisink, N. Y., on December 26, 1802. His maternal grandfather was Abel Shute, whose parents came from Holland and settled in Westchester County, New York. Both were Quakers. His paternal grandmother, Betsy Caton, and his paternal grandfather, John Stevens, were born in Orange County, New York. The forebears of his paternal grandmother were Irish Quakers, who came to America from the north of Ireland before the Revolution. Her grandfather was in the army of General Washington.

His mother, Martha Ann Shute, was born on October 2, 1826, at Horseheads, N. Y. His father, Noah Miller Stevens, was born on August 19, 1823, at Breesport, N. Y. He was a graduate of Oberlin College, Oberlin, Ohio, and a practicing attorney of great promise. He passed away at Athens, Pa., in the early part of his career, on February 6, 1853. After his father's death, Frank Stoddard Stevens went to live with his grandmother at Horseheads, N. Y., where he received his early education.

In September, 1869, he entered Cornell University. On March 13, 1871, Ezra Cornell, President of the University, sent him with a corps of engineers to make a survey for and construct the Utica, Ithaca, and Elmira Railroad, in which President Cornell was interested. Mr. Stevens advanced rapidly until, in 1876, he became Chief Engineer of that railroad. About this time the Utica, Ithaca, and Elmira Railroad Company became interested in the Cazenovia, Canastota, and DeRuyter Railway. Mr. Stevens was made Chief Engineer of this road also, and had exclusive charge of building the new line. He held this dual position until March, 1881, when he went to the Long Island Railroad Company as Chief Engineer, and built the Long Beach Marine Railway.

---

[1] Memoir prepared from information on file at the Headquarters of the Society.

Mr. Stevens then moved to Wisconsin as Locating Engineer on the Chippewa Valley and Superior Railway; and in December, 1881, he went to Texas as Superintendent of Construction of the Sabine and East Texas Railway. He was soon made Assistant General Superintendent, which position he left in 1883 to become Assistant Division Engineer on the New York, West Shore, and Buffalo Railway. From 1884 to 1885 he was Principal Assistant to the Chief Engineer of the road, and in 1885, became its Roadmaster. From 1886 to 1887 he was, successively, Engineer of Maintenance of Way of the New York, Ontario, and Western Railway and the Elmira, Cortland, and Northern Railroad. On November 12, 1887, he went to the Reading Company as Division Engineer, where he remained until his retirement from railway service, serving as Division Engineer, Superintendent, and Engineer of Maintenance of Way, successively, until October 31, 1923.

He was married to Anne Clapp, of Athens, Pa., on December 21, 1882. His wife died on September 7, 1922. He passed away at the home of his daughter, Helen (Stevens) Morrison, May 26, 1931, at Springfield, Mass., and was buried in Reading, Pa., on May 29, 1931, at the age of 80 years. Two children survive him, Helen (Stevens) Morrison, of Springfield, Mass., and Harold Allen Stevens, of Allentown, Pa. He is also survived by a grand-daughter, Elisebeth Stevens, of Allentown, and by two sisters, Mrs. Elisebeth (Stevens) Stevens, of Kansas City, Mo., and Mrs. Bertha W. Myers, of Horseheads, N. Y.

Mr. Stevens was a Thirty-second Degree Mason, having been admitted into Horseheads Lodge No. 364 soon after his twenty-first birthday. He was a Charter Member of the American Railway Engineering Association; and a member of the American Academy of Political Science, and the Franklin Institute of Philadelphia. From the time of its inception until 1923, or over a period of about twenty years, he was an unusually active member of the American Railway Engineering Association, serving on its most important committees and contributing the value of his knowledge as a maintenance-of-way student to their work. Many of the standards adopted by the Association during the years, 1902 to 1920, were due to his suggestions and recommendations.

He was quiet and unassuming in his manner, lending freely of his time to helping others. As a committee member he was invaluable and tireless in his efforts. He was a man of great versatility, not confining himself to a knowledge of any one subject. An ardent student of every branch of engineering and architecture, he possessed not only a theoretical but a practical knowledge as well. Mr. Stevens was entirely devoid of ostentation, which in a large measure accounted for his versatility being known only among the circle of his friends and associates. His general and technical knowledge covered a wide variety of subjects. He was courageous in maintaining his opinion, but did not force it upon others. He had his own ideals, but did not insist upon others accepting them. His hobby was work. Throughout his entire life, he was a most prodigious student. He was a man of irreproachable character and integrity, and his friends and the Engineering Profession have suffered a loss by his demise.

Mr. Stevens was elected a Member of the American Society of Civil Engineers on October 3, 1883.

LEWIS THORNBURG, M. Am. Soc. C. E.[1]

Died June 3, 1931

Lewis Thornburg, the son of Charles L. and Eulalia (Green) Thornburg, was born at Nashville, Tenn., on November 23, 1894, his father being at that time Head of the Department of Mathematics and Astronomy at Lehigh University, Bethlehem, Pa. The boy's early education was obtained in several private schools, including the Moravian Preparatory School, at Bethlehem. Following in the footsteps of his father, he showed an inclination early in life for mathematical and technical subjects, and attended Moravian College, at Bethlehem, for one year. In 1910, Mr. Thornburg entered Lehigh University, from which he was graduated with first honors and the degree of Civil Engineer in June, 1914. He was very active and popular in the student life during his college days, in addition to being very industrious. He became a Member of Beta Theta Pi Fraternity, and, as a reward for his scholarship, was elected a member of the Honorary Societies, Tau Beta Pi and Phi Beta Kappa.

During the summer vacations of his college course, Mr. Thornburg was always on the lookout for practical experience, and secured employment on various survey work and with the Construction Division of the Pennsylvania Railroad Company. After his graduation, he was appointed as Assistant to the Bursar of Lehigh University, and did private tutoring in college mathematics. Teaching, however, did not appeal to him particularly, and he was anxious to get into the practical field of engineering.

From May to October, 1915, he was employed as a Draftsman in the Engineering Division of the Standard Oil Company of New Jersey. He left this work and obtained a position as Draftsman in the Maintenance-of-Way Division of the Pennsylvania Railroad, where he was employed until February, 1916. He then went with the Lupton Steel Sash Company as a Sales Engineer, where he was engaged until November, 1917.

At this time, when every one was looking forward as to how they could best serve their country, Mr. Thornburg took the professional examination for a commission in the Civil Engineer Corps of the United States Navy. He passed this examination and, in January, 1918, was commissioned Assistant Civil Engineer, United States Navy, with the rank of Lieutenant (Junior Grade) (Temporary). After a short course of instruction at the United States Naval Academy, he was ordered to the First Naval District, Boston, Mass., as Assistant to the Public Works Officer. At that time the construction program for the Navy, in this locality, was quite large, amounting to about $3 000 000 worth of work. Lieut. Thornburg was given considerable responsibility for a man of his age and experience, and his work proved that such assignment was fully justified.

---

[1] Memoir prepared by L. B. Combs, Lt.-Comdr. (C. E. C.), U. S. N., Assoc. M. Am. Soc. C. E.

In April, 1920, he was commissioned Assistant Civil Engineer, United States Navy, with the rank of Lieutenant (Junior Grade) (Permanent), and was advanced to the rank of Lieutenant (Permanent) on July 1, 1920. From December, 1922, to August, 1923, he served as Assistant to the Project Manager for Naval Hospitals at the Bureau of Yards and Docks, and in active charge of contracts at the Naval Hospital, at Washington, D. C.

From August, 1923, to March, 1925, he was Assistant to the Public Works Officer at the Navy Yard, at Portsmouth, N. H., handling the design, construction, maintenance, and operation of all public works and public utilities at this Station. While on this duty he began some experimental concrete work, comprising the construction, installation, observation, and report of concrete piles in sea water. This investigation which is still underway, is being carried on, under the jurisdiction of the Bureau of Yards and Docks, Navy Department, for making observations and drawing conclusions which may be of value in designing and constructing reinforced concrete piles and water-front structures for use in sea water.

In April, 1925, Lieut. Thornburg was ordered to report as Assistant to the Public Works Officer, Eleventh Naval District, San Diego, Calif., and supervised the design, construction, maintenance, and operation of public works and public utilities at the Naval Training Station and the Naval Radio Stations in this District. In July, 1926, he was commissioned a Civil Engineer in the Navy and advanced to the rank of Lieutenant Commander. He served at San Diego, until March, 1929, when he was ordered to the Navy Yard at Mare Island, California, as Assistant to the Public Works Officer.

During his career in the Navy, Lt. Comdr. Thornburg had suffered frequently from illness, usually brought on by nervous strain and overwork. He was of such an active nature it was difficult for him to take things easily. In the spring of 1930, he became seriously ill and was transferred to the U. S. Naval Hospital, at San Diego, for treatment, where he was retired from the Naval Service on account of physical disability. He was much disappointed in having to accept retirement as he was very fond of the Service and his work, and regretted intensely the idea of giving up his active naval career. He apparently recovered his health to a certain extent, but was not satisfied and was always reaching out for new treatment which he thought might accomplish a complete physical recovery. With this idea in view, he went to the Mayo Clinic, in Rochester, Minn., in May, 1931, where a serious operation was found to be necessary, the shock of which his system was not able to stand.

He was married to Julia W., the daughter of Rear-Admiral H. A. Field, U. S. N., in February, 1926, who, with two daughters, survives him. He is also survived by his father and mother, three sisters, and four brothers. He was buried with military honors at Arlington National Cemetery, on June 8, 1931.

Lt. Comdr. Thornburg was elected an Associate Member of the American Society of Civil Engineers on December 15, 1924, and a Member on July 8, 1929.

LESTER WALDO TUCKER, M. Am. Soc. C. E.[1]

DIED MARCH 24, 1931

Lester Waldo Tucker was born on February 12, 1865, in Arcade, N. Y., of staunch New England parentage. His early education was obtained in the district schools of Northern Rhode Island, and he qualified in 1880 for entrance to the Scientific Department of the English and Classical School at Providence, R. I., from which he was graduated in 1882. Later in that year, he entered the City Engineer's Office in Providence, as Student and Rodman, continuing until 1886, successively, as Leveler and Transitman, on land surveys, preliminaries for water-works, sewers, harbor improvements, and various kinds of construction work.

From 1886 to 1888, Mr. Tucker was with the National Water Works Syndicate of Boston, Mass., as Construction Engineer on the water-works at Grafton and Bridgewater, Mass., Bath and Skowhegan, Me., and on surveys for other similar projects throughout New England. Later in 1888 and in 1889, he was associated with the late John W. Ellis, M. Am. Soc. C. E., of Woonsocket, R. I., engaged on surveys for several branch-line railways, and also on general city engineering.

In August, 1889, Mr. Tucker received appointment as Division Engineer with the St. Johnsbury and Lake Champlain Railroad Company, and also as Assistant Engineer for the Boston and Maine Railroad Company, with headquarters at St. Johnsbury, Vt. He continued in this position until October, 1892, and in addition to the regular maintenance and repair work, had charge of filling Pumpkin Hill High Trestle, which entailed the construction of a masonry bridge and the placing of more than 300 000 cu. yd. of material without serious interference with traffic; also, he was engaged on other similar work, including Walden Trestle, 125 ft. high, and requiring 200 000 cu. yd. of filling. Several bridges were constructed, together with engine terminals and the Buffalo Branch of the St. Johnsbury Railroad.

He re-entered the service of Mr. Ellis in 1892 as Resident Engineer in charge of the construction of Pratt Dam and a seven-span railroad bridge over the Blackstone River, at Lonsdale, R. I. Later, he had charge of the design and construction of other masonry dams at Slatersville, R. I., and Wilksonville, Mass.

From 1895 to 1902, Mr. Tucker was with the Boston and Maine Railroad Company, first as Assistant Engineer, and, later, as Engineer of Construction in charge of abolishing grade crossings in Boston, Arlington, and Beverly, Mass., together with eighteen crossings in connection with the double-tracking of the Eastern Division. He also had charge of improvements at the Mystic and Portland docks and the reconstruction of many bridges, stations, and other structures, including the design of a large amount of work for future construction.

---

[1] Memoir prepared by Messrs. E. J. Beugler, J. C. Boyd, George W. Burpee, and J. P. Snow, Members, Am. Soc. C. E.

In 1902, he became Resident Engineer for the New York Central and Hudson River Railroad Company at Albany, N. Y., in charge of construction work on the Hudson, Mohawk, and West Shore Divisions, including shops at West Albany, Union Station at Troy, N. Y., Oneida Station, Hudson River freight-line bridge, and tunnels near Fort Montgomery and Anthony's Nose. In the latter part of 1903, he was engaged in general contracting, in Massachusetts and New Hampshire, with an office at Boston. During 1904 and 1905, he was Division Engineer on the Delaware and Hudson Railroad at Schenectady, N. Y., in charge of grade-crossing abolishment and maintenance on the Delanson Division.

From 1905 to 1907, Mr. Tucker was, successively, Designing, Division, and First Assistant Engineer for the Lake Shore and Michigan Southern Railway Company. His work included the design of the Toledo Freight Transfer, changes in the Collinwood Yard, and other miscellaneous work on yards and structures; also charge of the construction of the Franklin and Clearfield Railroad, from Franklin to Brookville, Pa., entailing heavy grading, bridging, and several tunnels.

For the next thirteen years, Mr. Tucker was connected with Westinghouse, Church, Kerr, and Company, first as Engineer-in-Charge, subsequently, as Special Engineer, and then for seven years as Managing Engineer in charge of many important engagements, including investigations and reports on a large number of operating properties and projects; the design and construction of steam and electric railway facilities, hydro-electric and steam power, industrial plants, coast protection, and other works throughout the United States, Canada, and Cuba. Outstanding among these are: A report on the physical condition and maintenance of the Southern Pacific Railroad Lines in Louisiana and Texas; a survey and valuation of the property of the American Agricultural Chemical Company (68 plants located in 20 States); reconstruction of the Arkansas and Louisiana Midland Railroad (50 miles); relining two single-track tunnels on the Pittsburgh and Shawmut Railroad, without interference with heavy traffic; building a fertilizer plant and deep-water quay at Matanzas, Cuba, for the Armour Company; and the construction of a sugar refinery at Savannah, Ga.

In 1920, Westinghouse, Church, Kerr, and Company was merged with Dwight P. Robinson and Company and Mr. Tucker continued with the combined organization on general engineering and construction until 1921, when he became Chief Engineer of Henry R. Kent and Company, Rutherford, N. J. The latter engagement covered a large amount of power-house work, including installations for Cornell University, Lock Haven (Pa.), Electric Light and Power Company, the Worcester (Mass.), Electric Light Company, and at various points on the New York, New Haven, and Hartford Railroad; also factory work, hotels, and other construction.

In 1925, he became associated with Haven and Hopkins, Engineers, at Boston, on general engineering and valuation. Later, until his death, he continued in business for himself as Consulting Engineer. As such, his work included considerable reconstruction in Vermont to make good the damage caused by the 1927 flood in New England, and general consulting practice.

After an unusually active career in connection with a wide range of engineering work, Mr. Tucker's sudden death at St. Petersburg, Fla., on March 24, 1931, came as a shock to his many friends and associates.

An outstanding trait was his resourcefulness in tackling difficult undertakings and reducing them to a common-sense basis. He solved most of his problems by the application of common sense rather than mathematics. He applied unlimited energy to any work in hand and followed a consistent schedule until the task was completed. He had good executive ability, largely due to the co-operative spirit toward and consideration shown to his assistants and associates. Men working under or with him had the satisfaction of knowing that their combined team work would give the desired result with little or no lost motion. He had an unusual amount of enthusiasm and the ability to transmit this enthusiasm to others. He never had any difficulty in surrounding himself with good assistants, because of the initiative which he allowed to his assistants and the consequent pride which they took in their work. He was extremely big-hearted and took a deep interest in the progress of his subordinates, going out of his way to teach them everything that he knew about the subject on which they might be engaged at the time.

Mr. Tucker was an Associate Member of the American Railway Engineering Association and a Member of the Boston Society of Civil Engineers. He was a Knight Templar and one of the oldest members of the Mystic Shrine of Montpelier, Vt.; he was also a member of the Engineers Club of Boston and the Boston City Club. He was a member of the Protestant Episcopal Church.

On September 26, 1892, Mr. Tucker was married at St. Johnsbury, Vt., to Bessie Thompson, who survives him.

Mr. Tucker was elected a Member of the American Society of Civil Engineers on December 4, 1901.

WILLIAM FRANCIS TYE, M. Am. Soc. C. E.[1]

Died January 9, 1932

William Francis Tye was born on March 5, 1861, in Haysville, Ont., Canada, the son of Francis Edward and Ann (Skelley) Tye. Mr. Tye received his higher education at the University of Ottawa, Ottawa, Ont., Canada, and the School of Practical Science of Toronto University. He began his professional career early in 1881 as Chainman on Dominion Land Surveys.

From the early spring of 1882 to December, 1885, he acted in various capacities from Rodman to Assistant Engineer on the construction of the main line of the Canadian Pacific Railway, between Brandon, Man., and Griffith Lake, B. C., Canada.

---

[1] Memoir prepared by John G. Sullivan and F. P. Gutelius, Members, Am. Soc. C. E.

From the spring of 1886 to the late fall of 1887 he was an Assistant Engineer on construction and Transitman on location for the St. Paul, Minneapolis, and Manitoba Railway (now the Great Northern Railroad).

Mr. Tye then went to Mexico and for a year was Track and Bridge Engineer on the Mexican Central Railway. During 1889, he was engaged as a Mining Engineer in Mexico.

From February, 1890, to the fall of the same year, Mr. Tye was Division Engineer in charge of the location and construction of the Great Falls and Canada Railway, in Montana, and from October, 1890, to May, 1893, he was with the Great Northern Railway Company as Locating Engineer and Division Engineer in charge of construction west of the summit of the Cascade Range, in Washington. He had charge of the construction of all that part of the Great Northern Railway west of the old Cascade Tunnel which was abandoned after the construction of the new 8-mile tunnel.

In 1893 and 1894, Mr. Tye was Chief Engineer of the Alberta Railway; in 1895, Chief Engineer of the Kaslo and Slocan Railway; and from 1896 to 1899, Chief Engineer of the Columbia and Western Railway. These three railways are now included in the Canadian Pacific System.

After the completion of the Columbia and Western Railway to Midway, B. C., Mr. Tye was appointed Chief Engineer of Construction of the Canadian Pacific System. In the spring of 1900 his title was changed to Assistant Chief Engineer, and, in 1904, he became Chief Engineer of the Canadian Pacific System, this position he retained until 1906, when he retired to enter private practice as a Consulting Engineer.

Mr. Tye's vast experience, and his well-earned reputation for fairness and clear thinking, made his professional opinion sought in connection with a number of important projects. His paper[2] on "Canada's Railway Problem and Its Solution" won for him the Gzowski Medal of the Canadian Society of Civil Engineers (now the Engineering Institute of Canada), in 1917.

In the spring of 1898, Mr. Tye was married to Mable Maloney, in London, Ont. He practically retired from active business about 1920, when he left Canada to live in Europe, and he and his wife traveled very extensively in Egypt, Spain, Italy, England, Scotland, France, and Switzerland. They were on their way from Switzerland, planning to return to Canada, when Mr. Tye was suddenly taken ill on the night train between Cannes and Paris, and died in Paris on January 9, 1932, less than 36 hours after arriving there. He was the last of his immediate family and is survived only by his widow.

Mr. Tye always took an actve part in the promotion of engineering ideas and, in addition to his membership in the Society, he was for more than thirty-five years a member of the Engineering Institute of Canada, in which he held various offices, being President in 1912. He was among the first to join the American Railway Engineering Association, and was an active member for more than twenty-five years. He joined the Institution of Civil Engineers (Great Britain) as a member in 1910, and was the Canadian member of the Council of that Institution during 1916 and 1917, and 1917 and 1918. He was also an active member of many social clubs, among which may be mentioned the St. James Club, of Montreal, the York Club, of Toronto, and the Manitoba Club, of Winnipeg. Mr. Tye was a member of the Roman Catholic Church.

---

[2] *Transactions*, Canadian Soc. of Civ. Engrs., January-June, 1917.

Of outstanding professional ability, truthfulness, and honesty, Mr. Tye was respected and loved by all who worked under his direction, and his death is deeply regretted by his wide circle of friends and by all members of the profession who knew him.

Mr. Tye was elected a Member of the American Society of Civil Engineers on September 1, 1897.

GEORGE WILLIAM VOLCKMAN, M. Am. Soc. C. E.[1]

Died July 15, 1931

George William Volckman was born at Stratford, Essex, England, on March 27, 1873, the second son of Charles and Elizabeth Volckman. His father, grandfather, and great-grandfather were all Freemen of the City of London. He was educated at Dulwich College and in the Engineering Department of King's College, in London.

Mr. Volckman gained his first practical experience on the construction of the Manchester Ship Canal, first as a pupil, and, later, as an Assistant Engineer on the Contractor's Staff. The work upon which he was engaged comprised two very heavy sections, 7 miles in length, and included large quantities of rock and earth excavation, canal and river embankment and walls, canal and river locks, sluices, swing bridges, and the diversion of sewers and water supply mains.

From 1893 to 1896, he was Contractors' Engineer on the construction of two dry docks for the British Admiralty at Portsmouth, England. After the first year, the work on these docks was carried on continuously day and night and was completed in three years, or two years before the contract time. At the same time that the two docks were under construction, Mr. Volckman was acting as Contractors' Engineer on the dredging of 1 000 000 cu. yd. of gravel from the entrance channel to Portsmouth Harbor, to a depth of 36 ft. at low water.

From 1896 to 1898, Mr. Volckman was Contractors' Engineer on the construction of a 3¼-mile length of the Central London Tube Railway, including double-shield driven tube tunnels and station tunnels. For the next two years he was engaged as Contractors' Engineer on the construction of the Crowhurst, Sidley, and Bexhill Railway, in Sussex, England, a branch line 4½ miles in length, embracing heavy main-line permanent way, a brickwork viaduct with sixteen arches of 60-ft. span, the pier foundation of which had to be carried down in timbered trenches through peat and earth bog, in many cases, to 50 ft. below ground level.

---

[1] Memoir prepared by Gerald Fitz-Gibbon, Esq., Hampstead, England.

The next year (1899), he was employed as Contractors' Sub-Agent and Engineer on the construction of the Whitechapel and Bow Railway, an extension of the London Underground Railway to connect with the London, Tilbury, and Southend Railway. This was a heavy piece of engineering work done by the "cut and cover" method. From 1900 to 1902, Mr. Volckman carried out several important engineering works, mostly in connection with railway or docks in England, as Contractors' Agent and Engineer.

From 1902 to 1907, he was engaged for the contracting firm of C. H. Walker and Company, Limited, of Westminister, as Agent and Engineer in charge of the construction of the extension of H. M. Dockyard, in Bermuda, for the British Admiralty. The works included the removal of a rock cliff ½ mile in length, on the coast line of Ireland Island, and the reclamation of the foreshore to form a quay. The quay wall, 2 200 ft. long, in 35 ft. of water, was built of 10-ton concrete facing blocks with mass concrete backing. A breakwater, 3 000 ft. in length, extended from one end of the quay wall, being constructed of 10 to 13-ton concrete blocks laid sloping on a rubble stone foundation in a depth of water running up to a maximum of 60 ft. At the same time, Mr. Volckman was engaged in carrying out, for his Company, the reconstruction of all the batteries surrounding the dockyard, and inspecting, reporting on, and making designs and estimates for large engineering works in South America. He also visited Canada and inspected and reported on the route of the proposed Montreal, Ottawa, and Georgian Bay Canal.

From 1908 to 1927, he resided in Ottawa, Ont., Canada, as Engineer for the proposed canal and surveyed the route, designed the necessary locks, dams, etc., and made detailed estimates of the cost of the work. He was also Vice-President, General Manager, and Chief Engineer of the Canadian Engineering-Contracting Company of MacArthur Perks and Company, Limited, from 1909 to 1927. During this time he examined and reported on many large propositions in Canada, the United States, and in other countries, including work executed by his Company for the Southern Pacific Railway, in Oregon, and the construction of docks at Havana, Cuba.

In 1928, Mr. Volckman was engaged by the firm of Sir Alexander Gibb and Partners, the eminent Consulting Engineers of Westminster, as its Representative resident in Bombay of all the firm's Indian work. He was on leave when he died in a London Nursing Home after a serious operation, on July 15, 1931, at the age of 58 years. In 1923, he was married to Anna Maude West, who survives him.

From the outset of his career, Mr. Volckman had exceptional opportunities for gaining experience in the construction of large engineering works of a widely varied character, and he took the fullest advantage of such opportunities. He was a most capable and energetic Engineer, and it would not be possible to speak too highly of his industry, character, or professional ability.

Mr. Volckman was elected a Member of the American Society of Civil Engineers on March 5, 1912. He was also a Member of the Institution of Civil Engineers, of London, and of the Engineering Institute of Canada.

FRED J. WAGNER, M. Am. Soc. C. E.[1]

Died May 24, 1930

Fred J. Wagner was born on June 30, 1870, in Georgetown, N. Y., the son of Charles C. and Marcelia (Jones) Wagner.

Mr. Wagner attended the local schools and after his graduation from Cazenovia Seminary in 1890, he entered Union College at Schenectady, N. Y., with the class of 1894, in the Civil Engineering Course. He was a member of the Phi Delta Theta fraternity. During the college vacations, Mr. Wagner was employed in the New York State Engineer's Department as an Assistant to the Engineer in Charge of the construction of a spillway for the Eaton Brook Reservoir, the Genesee Street lift bridge over the Erie Canal, at Utica, N. Y., and other State construction projects.

From 1894 to 1910, Mr. Wagner was continuously in the State Engineer's Department, advancing through all the then established civil service grades to and including that of First Resident Engineer. During the first part of that period, he had field charge of the construction of many important contracts, among them being a difficult repair job on the apron of a State dam at Minetto, N. Y., on the Oswego River; a stone dam at Baldwinsville, on the Seneca River; four important lift and bascule bridges over the Erie Canal at Syracuse, Utica, and Canastota; a concrete dam across the Black River at Forestport, N. Y.; and a sea-wall at Auburn, N. Y., on Owasco Lake.

In 1905 and 1906, Mr. Wagner was in charge of Barge Canal Contract No. 4 at Sylvan Beach, N. Y., which involved the construction of a lock, bridges, breakwater, and several miles of channel dredging. This contract presented some unusual difficulties, due to the character of the sand encountered. While not a quicksand, this material would assume an exceedingly flat slope when submerged and its control was a serious problem. Following 1906, Mr. Wagner was in charge of a section of more than 25 miles of Barge Canal Route, completing the surveys and making preliminary plans and estimates for future contracts. The surveys and plans of this section were complicated by several railroad and highway intersections which necessitated relocation and adjustment of grades.

In 1909, he was again promoted, this time to the position of First Resident Engineer with headquarters at Syracuse, in general charge and supervision of all Barge Canal contracts then in force on the Middle Division, which covered approximately 140 miles, comprising the Cayuga and Seneca, the Oswego, and about one-third of the Erie, Canals. During this time, a large engineering force was required to man the contract and survey parties, the chiefs of all the different parties reporting to Mr. Wagner and acting under his orders.

In 1910, Mr. Wagner resigned from the State service and became associated with the Scott Brothers Construction Company, as Chief Engineer. From that time until 1916, he had engineering charge for the contractors of important Barge Canal work, comprising heavy excavation, concrete structures of many kinds, bridges, etc.

---

[1] Memoir prepared by George D. Williams, M. Am. Soc. C. E.

In 1917, he accepted a position as Advisory Engineer for the New York State Department of Public Works. Just before the outbreak, and during the first few months, of the World War, many State contracts had been let and were under way. The attendant economic upheaval and general dislocation of peace-time industries had made further progress impossible, in many cases, necessary materials being no longer available and all the construction forces being rapidly demanned by reason of the men being drawn into industries engaged in manufacturing munitions. To make arrangements to close, suspend, or complete those contracts on a basis equitable to the State and the contractors, required a considerable knowledge of general conditions, of engineering, contracting possibilities, fairness, and justice. Mr. Wagner was largely instrumental in making the necessary adjustments to co-ordinate such contracts with the conditions then existing.

Having completed this work successfully, he opened an office as Consulting Engineer in Oneida, N Y., and also accepted the position of County Superintendent of Highways for Madison County, New York, which position he occupied until his death. During this period of his life, he was Consultant on several important projects both as adviser to other engineers and for contractors on heavy construction, his experience having prepared him thoroughly for both these classes of work.

For several years, the City of Oneida had been hampered in its business growth and as a residential city by an unsatisfactory and inadequate water supply, which was impounded a short distance south of the city among hills of limestone formation. The collectible quantity was small and the quality poor, being hard and unsuitable either for industrial or domestic purposes. Agitation for a supply, better both in quantity and quality, had long been carried on by many far-sighted citizens. In 1927, this agitation crystallized into action, and Mr. Wagner was engaged as Consulting Engineer for the City. The source chosen was on Florence Creek, near its head-waters. This stream flows southerly from the hilly plateau in the northern part of Oneida County and, eventually, its waters find their way into Oneida Lake. The reservoir site selected is in a sparsely settled sandy country which provides natural filterage in large part and in which danger of pollution is practically negligible. The system included a dam and reservoir of considerable size, about twenty miles of conduit, a distributing reservoir, and connection with the existing city mains. Under Mr. Wagner's supervision the work was carried to a successful conclusion.

In New York State, in addition to the through routes and other important roads which are built by the State, the individual counties annually construct a large mileage of permanent surfaced roads, many of which are of importance. The method under which Madison County operated was to build by its own forces. Mr. Wagner organized a construction force for the County with all the equipment necessary to build roads and, during this period, was actively engaged in county road construction, together with the building of such bridges as came under his jurisdiction. A large mileage of well-planned and executed concrete and bituminous roads as well as numerous bridges will bear witness for years to his ability. During this period and on this work, the results of his broad experience in engineering and contracting were most evident. His success there was due to his engineering knowledge and his experience as an organizer and practical constructor.

Mr. Wagner was a member of Georgetown Lodge, F. and A. M., and after locating in Oneida he joined and maintained an active interest in Oneida Lodge No. 767 Benevolent and Protective Order of Elks, and the Rotary Club of that City.

He was the descendant of pioneering ancestors and like them, looked on difficulties and obstacles as things not to be avoided if they were in his path, but to be overcome. Due partly to his early environment, family training, and inherited trend of mind, and partly to his experience as a consultant and as an engineer in contracting, he had developed to a high degree the faculty of quickly considering all accessible viewpoints of a question before coming to a decision. This faculty made it easy for him to understand another's opinion and possible for him to differ on questions of county construction policy and still maintain harmonious relations.

Mr. Wagner possessed a genial and winning nature. He was kindly and courteous both in his official and in his social relations. He was held in high esteem not only for his ability as an engineer and constructor, but also for his uprightness and usefulness as a citizen.

Mr. Wagner was married, in 1893, to Cora Brown, of Cortland, N. Y., who survives him, with two daughters, Marcelia Wagner and Hazel Wagner Lavender, and a son, Charles C. Wagner.

Mr. Wagner was elected an Associate Member of the American Society of Civil Engineers on April 4, 1906, and a Member on September 6, 1910.

SAMUEL TOBIAS WAGNER, M. Am. Soc. C. E.[1]

Died August 7, 1931

Samuel Tobias Wagner, the son of John and Sara A. (Wood) Wagner, was born in Philadelphia, Pa., on August 30, 1861. He attended the University of Pennsylvania, receiving the degree of Bachelor of Science in 1881, and, three years later, that of Civil Engineer from the same institution.

On leaving college, Mr. Wagner was employed by the Phœnix Bridge Company, at Phœnixville, Pa., and, in the period from 1881 to 1890, he held, successively, the positions of Draftsman, Assistant to the Master Mechanic, and Superintendent of Shops. From 1890 to 1893, he was a Resident Engineer for the Company, in Louisville, Ky.

---

[1] Memoir prepared by a Committee of the Philadelphia Section consisting of S. M. Swaab, *Chairman,* R. I. D. Ashbridge, Clark Dillenbeck, and E. B. Temple, Members, Am. Soc. C. E.

He entered the employ of the Bureau of Surveys of the City of Philadelphia in 1894, as Assistant Engineer in charge of the Reading Railroad Subway and Tunnel on Pennsylvania Avenue. This work was described by Mr. Wagner and the late George S. Webster, Past-President, Am. Soc. C. E., in a paper[2] presented before the Society entitled "The Pennsylvania Avenue Subway and Tunnel, Philadelphia, Pa."

Upon the completion of this work, Mr. Wagner was appointed Assistant Engineer in Charge of the Improvement and Filtration of the Water Supply of Philadelphia, which position he held from 1900 to 1902, inclusive, when he entered the service of the Philadelphia and Reading Railroad Company as Assistant Engineer on the elevation of tracks on Ninth Street, in Philadelphia. This work occupied his time from 1902 to 1915, when he was appointed to the position of Chief Engineer of the Philadelphia and Reading Company (now the Reading Company). At the time of his death, he held the position of Consulting Engineer to that Company.

He wrote a number of papers and prepared numerous discussions for the Society, one of which, in 1914, received the James Laurie Prize.[3]

Mr. Wagner was a Fellow of the American Association for the Advancement of Science; a member of the American Railway Engineering Association; the American Society for Testing Materials, of which he was Vice-President; the Franklin Institute, of which he was a Director; the Philadelphia Academy of Natural Sciences; and President of the Board of Trustees of the Wagner Free Institute of Science, a free co-educational institution founded by one of his forebears. Mr. Wagner lectured for many years on Civil Engineering at this institution, and was succeeded by one of his sons. He was also a member of the General Alumni Association and a Past-President of the Engineering Alumni Society of the University of Pennsylvania; a member of the Engineers Club of Philadelphia; and a Vestryman of the Protestant Episcopal Church of St. James the Less, Philadelphia, and was active in this capacity. Until a short time before his death, he was a member of the State Registration Board for Professional Engineers in Pennsylvania.

Mr. Wagner was married on November 13, 1888, to Mary C. R. Scull who, with four children, Mary, John, William Worrell, and Thomas Rowan, survives him.

He was a man of great energy and activity, deeply interested in his profession. He possessed ripe judgment and a thorough knowledge of engineering, gained in many years of experience and contact with important engineering works, and was held in high esteem by all who knew him. Any commentary on Mr. Wagner's life would be incomplete, that failed to emphasize his fine personality, lovable character, and high sense of duty, which endeared him to his many friends and associates. With his passing, the Engineering Profession has lost one who, during his whole career, exemplified and upheld its highest traditions.

---

[2] *Transactions*, Am. Soc. C. E., Vol. XLVIII (1902), p. 470.

[3] "The Elevation of the Tracks of the Philadelphia, Germantown, and Norristown Railroad, Philadelphia, Pa.", *Transactions*, Am. Soc. C. E., Vol. LXXVI (1913), p. 1819.

He had recently celebrated the Fiftieth Anniversary of his graduation from college, and although, at the time of his death, he was seventy years of age, he was more than usually active; as a matter of fact, his untimely death resulted from his physical activities.

Mr. Wagner was elected a Member of the American Society of Civil Engineers on February 2, 1887. He served as Director of the Society from 1918 to 1920, and as President of the Philadelphia Section in 1917 and 1918.

JOHN SIMPSON WALKER, M. Am. Soc. C. E.[1]

Died May 12, 1931

John Simpson Walker was born at Florence, Ala., on July 2, 1849. His father was Richard Wilde Walker, a Confederate States Senator and, later, Judge of the Superior Court of Alabama. His mother was Mary Ann (Simpson) Walker, of Florence, Ala.

Mr. Walker was educated at private schools and at the University of Virginia. His first work in engineering was as Assistant Engineer with the State Board of Improvement, Mobile Bay, during 1871 and 1872. He served as Assistant Engineer with the Corps of Engineers, United States Army, on the survey of the Tombigbee River, in November and December, 1872.

In 1873, he became Resident Engineer on the Savannah and Memphis Railroad and in June of that year, he was appointed Private Secretary to the late A. L. Rives, M. Am. Soc. C. E., Chief Engineer and General Superintendent for the Mobile and Ohio Railroad Company. In 1874, Mr. Walker was placed in charge of improvements in the Mobile Yard and Round-House, at Whistler, Ala. He remained with this Company until September, 1876, as Assistant Division Superintendent and Division Superintendent, respectively, in charge of transportation and maintenance. He then became Assistant Engineer in charge of location for the Mexican National Railroad Company; Engineer for the Vicksburg, Shreveport, and Pacific Railroad Company; and Engineer of the Birmingham, Ala., Water-Works, in which position he had charge of the construction of the extension at Cahaba.

On June 5, 1881, he was appointed U. S. Assistant Engineer, on the improvement of Elk River Shoals, on the Tennessee River. Mr. Walker was engaged in private practice at Huntsville, Ala., from December, 1883, until February 1, 1891, when he became Assistant Engineer in the office of the U. S. District Engineer, at Nashville, Tenn. He remained in this position until his retirement, on an annuity, on August 20, 1922. Practically all the locks and dams in the Cumberland River, above Nashville, and some of those below the city, were constructed under his supervision.

Mr. Walker was the ninth Charter Member of the Engineering Association of the South, organized at Nashville in 1889 and chartered in 1892. He was made an Honorary Member of the Engineering Association of Nashville on May 9, 1921. Upon his retirement from active service, the City of Nashville honored him by the presentation of an inscribed cane in recognition of his great service to the community while he was a resident of Nashville.

---

[1] Memoir prepared by Hunter McDonald, Past-President, Am. Soc. C. E.

Mr. Walker was a great student, modest and retiring in disposition, genial and friendly among those with whom he became intimate. His reading was wide, and, in addition to his outstanding engineering knowledge, he was well versed in history and literature.

After his retirement, except for a year spent with his son, Colonel Walker, at Fort Leavenworth, Kansas, and at Fort Meade, South Dakota, Mr. Walker made his home at the Tulane Hotel, in Nashville, until his death on May 12, 1931. A prayer service was read at Nashville by the Rev. J. F. McCloud, Assistant Rector of Christ Protestant Episcopal Church, and the funeral took place at Huntsville, Ala., on May 15, 1931.

He was married in 1875 to Nani Herndon Rice, at Mobile, Ala. Mrs. Walker died several years before him. In addition to his son and only child, Col. Richard W. Walker, U. S. A., and four grand-children, he is survived by two brothers, Judge Richard W. Walker, of Huntsville, and Percy H. Walker, Chemist, Bureau of Standards, at Washington, D. C., and a sister, Mrs. John M. Bolling, of Huntsville.

Mr. Walker was elected a Member of the American Society of Civil Engineers on January 5, 1881.

ANDREW JACKSON WILEY, M. Am. Soc. C. E.[1]

Died October 8, 1931

The sudden and unexpected death of Andrew Jackson Wiley ended an engineering career of notable achievements. For nearly half a century Mr. Wiley was identified with the engineering development of the West, especially in irrigation work and in the construction of many of its outstanding dams. His professional connections covered most of the Western States, in addition to India, the West Indies, and the Panama Canal Zone. When death overtook him, his consulting engagements included such outstanding projects as the \$165 000 000 Boulder Canyon Project of the United States Bureau of Reclamation, the \$220 000 000 aqueduct of the Metropolitan Water District of Southern California, and the \$400 000 000 Columbia Basin Project under investigation by the Government in the State of Washington.

Andrew Jackson Wiley was born in New Castle County, Delaware, on July 15, 1862, the son of John and Mary Wiley. He attended the Newark Academy in Newark, Del., graduating at the head of his Class and winning a scholarship to Delaware College. He was graduated from Delaware College as Valedictorian of his Class in 1882, with the degree of Bachelor of Philosophy in Engineering.

---

[1] Memoir prepared by J. L. Savage, M. Am. Soc. C. E.

After his graduation Mr. Wiley spent a year on surveys and construction for the Baltimore and Ohio Railroad Company in Delaware and Maryland. His first assignment on irrigation work, and the connection which established him in the West, extended from 1883 to 1886, when he served as Rodman and Assistant Engineer with the Idaho Mining and Irrigation Company, of Boise, Idaho. From 1886 to 1888 he was Assistant Engineer on construction for the Union Pacific Railroad Company, at Butte, Mont., but returned to irrigation work in Idaho in 1888. From this time until 1892 he was Chief Assistant Engineer for the Idaho Mining and Irrigation Company, on the construction of an irrigation project in Southern Idaho. From 1892 to 1898 he was Chief Engineer and Manager of the Owyhee Land and Irrigation Company, constructing a large irrigation project near Grandview, Idaho.

This period of his long experience was perhaps the most uncertain and trying time in his life, due to the financial pitfalls which constantly faced these developments. The mining operations connected with these early developments, although promising at first, were fraught with many disappointments and often ended in financial failure. The land development and irrigation work was most difficult and discouraging during that period of agricultural and financial depression when prosperity was always "just around the corner." These were years of adventure and of great effort and personal sacrifice on Mr. Wiley's part.

Some of his friends refer to this period in Mr. Wiley's life as his "lean years." Measured by dollars received, the results of his labor were almost nil, but he made many friends among the mining and irrigation fraternities. He was known to many leading business men of Idaho, and to many officials in Washington, D. C., as a man of integrity, whose word alone was a guaranty of performance. His opinion in relation to the development of the water and land resources of the desert regions was accepted and valued by those who knew him. His knowledge of the gold value of Snake River gravels was usually considered final and, from time to time, he was employed to examine tracts that had been presented to financiers for promotion. During this period he had many days when work was not pressing, but they were happy days, when the tendrils of his friendship were finding their way deep into the hearts of all with whom he came in contact, from teamsters to investment bankers; from prospectors to enterprising promoters.

It was about 1900 when the "corner" was finally turned and prosperity overtaken. The population of the arid inter-mountain States had greatly increased and plans for the further development of irrigation were being seriously considered. Hydraulic engineers were also scouting in the interest of the great utility companies for favorable sites for the development of hydro-electric power. Southern Idaho received its full share of attention, and this period marks the beginning of Mr. Wiley's intensive activities in both these fields. Probably one of the brightest spots in Mr. Wiley's early experience was his association with the famed engineer, Arthur D. Foote, M. Am. Soc. C. E., in the first construction work of the New York Canal, one of the early irrigation developments in Boise Valley.

Following these early beginnings Mr. Wiley worked through the next thirty years on a continuous procession of great irrigation and power projects in Idaho, Oregon, California, and other States in the West. His contacts were with the large Carey Act companies, irrigation districts, power development companies, and municipalities.

A partial list of the large non-Federal projects on which Mr. Wiley acted in a consulting capacity includes the following: 1900–02, Swan Falls, Idaho, power plant and later extensions; Trade Dollar Mining Company, Idaho; 1902–04, Chief Engineer, Boise-Payette River Electric Power Company; Horseshoe Bend power plant, Idaho; Granite Springs Dam, City of Cheyenne, Wyo.; 1904–05, Barber Lumber Company dam and power plant, Idaho; 1906–14, repairs and extensions, Milner Dam, Idaho; Twin Falls North Side Irrigation Project, Idaho; Twin Falls-Oakley Project, including Oakley Dam, Idaho; Shoshone Falls power plant, Idaho; Lower Salmon Falls power plant, Idaho; Salmon River Dam and Irrigation Project, Idaho; Belleview Dam and power plant, Idaho; Payette River Dam and power plant, Idaho; American Falls power plant, Idaho; Southern Alberta Land and Irrigation District, Canada; 1914–20, Ochoco Dam and Irrigation District, Oregon; Warm Springs Dam and Irrigation District, Oregon; Grants Pass Irrigation District, Oregon; Sweetwater Dam, San Diego, Calif.; 1920–26, Don Pedro Dam and power plant for Turlock and Modesto Irrigation Districts, California; Murphy Dam, Big Wood River Dam, and Mackay Dam, Idaho; projects for Kern River Water Storage District, California; Crow Creek Irrigation District, Montana; projects for San Joaquin River Water Storage District, California; Exchequer Dam and power plant for Merced Irrigation District, California; Melones Dam for South San Joaquin and Oakdale Irrigation District, California; reconstruction of irrigation system, Bitter Root Valley Irrigation District, Montana; reconstruction of irrigation system, West Okanogan Irrigation District, Washington; Logan City, Utah, power plant; Washington Water Power Company, Spokane, Wash.; Blitzen River Reclamation District, Malheur Land and Cattle Company, Oregon; Bull River Dam, Oregon; 1927–31, Sutlej River Project, in India, for the British Government; Reeder Gulch Dam, Ashland, Ore.; reviewing design and stability, Lower Otay, Barrett, Morena, Chollas Heights, and Hodges Dams for San Diego, Calif.; investigation of St. Francis Dam disaster for Los Angeles, Calif.; Los Angeles County Flood Control District, California; reconstruction of the Lafayette Dam, California; flood control project for Orange County, California; Don Pedro power plant, California; and San Gabriel Dam, California.

During much of the period when Mr. Wiley was engrossed with his work for private companies, he was also engaged in a consulting capacity by the United States Bureau of Reclamation. He served as Consulting Engineer for the Bureau from the inception of its reclamation work in 1902, and from 1925 held an appointment as Consulting Engineer for the Interior Department at large.

He was consulted in connection with the design and construction of such major Government dams as the Belle Fourche, Shoshone, Lower Yellowstone, Roosevelt, Pathfinder, Minidoka, Jackson Lake, Arrowrock, Cold Springs, Sun River Diversion, Tieton, Black Canyon (Idaho), McKay, American Falls, Guernsey, Gibson, Stoney Gorge, Deadwood, Echo, Owyhee, Cle Elum, Boise Diversion, Deer Flat (Upper and Lower), Dodson, Conconnully, Vandalia, Sherburne Lakes, Hubbart, Gerber, Coolidge, and Hoover. His consideration of these projects included intimate studies of many of the design features, in addition to periodical field inspections during construction.

In the case of most of these dams the foundation conditions were carefully inspected and approved by Mr. Wiley before the construction was permitted to be started. Likewise, the concrete materials, mixtures, and control, the character of the embankment materials, methods of compacting, and many other fundamental construction details were submitted to him for review and approval.

The officials of the Bureau of Reclamation, and his associates among the engineers of the Bureau, had implicit confidence in his judgment, and felt a genuine sense of security when his approval of a project had been given.

While the foregoing list mentions dams only, Mr. Wiley's assignments for the Bureau of Reclamation were by no means limited to that field. He was consulted in connection with the design and construction of many other features of Government irrigation and power projects, particularly in regard to the main canals and important canal structures, including diversion works, tunnels, flumes, siphons, bridges, and wasteways.

It is not surprising that with his background of twenty-eight years' service in Government reclamation work, and an even longer record on Carey Act and district irrigation and power development, Mr. Wiley was the first engineer selected for the Hoover Dam Consulting Board. His broad experience and sound judgment were invaluable in connection with the preliminary studies of this stupendous project. This was especially so, when the recent unemployment situation created an emergency which suddenly shortened the allotted time for the completion of the designs and specifications a matter of six months.

Mr. Wiley's extensive experience in the design of dams and power plants was also recognized and utilized by other departments of the Federal Government. He was Consulting Engineer for the United States Indian Service on the design and construction of the Coolidge Dam in Arizona; he also prepared reports on the feasibility and method of constructing the Kickinghorse Storage Dam, the raising of the Tabor and Pablo Dams, and plans for the Lower Crowe and Twin Reservoir Dams, on the Flathead Project, in Montana. The Panama Canal Zone selected him as one of the Consultants on the design of the Madden Dam and power plant, the contract for the construction of which has only recently been awarded. He was consulted during the summer of 1931 by the United States War Department in connection with the major structures on the great Columbia Basin Power and Irrigation Project in the State of Washington.

Any engineer with such an impressive list of successful projects to his credit could not fail to receive international notice. Mr. Wiley acted as Consulting Engineer for the British Government from October, 1927, to February, 1928, in the preliminary investigation of twenty-six dam sites in the

Himalayan Mountains in India. One of these sites proved suitable for a large storage project, and careful design studies were made, under Mr. Wiley's direction, for a dam about 500 ft. high, known as the Bhakra Dam, which it is proposed to construct at this site.

In 1927, Mr. Wiley visited Porto Rico in connection with the Guajataca Dam of the Isabella Irrigation Service. He again visited the Island in 1929 in connection with the Guineo Dam, and a third time in 1931 in connection with the Guineo and Metrullas Dams, all of these assignments being for the Porto Rico Government Irrigation Service.

When stricken, Mr. Wiley was engaged on work in San Gabriel Canyon, California, where the Los Angeles Flood Control District is planning two flood-control dams. He was also in California for conferences in connection with the great aqueduct which will carry Colorado River water to Los Angeles and the surrounding Metropolitan District. He had also been requested to reserve time during the latter part of November for an important meeting of the Hoover Dam Consulting Board.

It is significant of Mr. Wiley's career as a designer and builder of important dams that he was Consulting Engineer on the succession of the ranking high masonry dams of the world, as follows: Shoshone (1905–10), height, 328 ft.; Arrowrock (1911–15), height, 349 ft.; Owyhee (1928–32), height, 405 ft. (530 ft. in fault zone); Bhakra, India (1928), height, 500 ft.; and Hoover (1930), height, 727 ft.

Following the great St. Francis Dam disaster in Southern California on March 13, 1928, great official and public concern was felt as to the safety of all storage dams whose failure might endanger life. On this account the Secretary of the Interior, on March 15, 1928, ordered that all such dams of the Bureau of Reclamation be promptly examined by a competent engineer and reported on as to their safety. It is significant of the confidence had in Mr. Wiley's judgment and ability that he was chosen in this connection to report on twenty of the more important storage dams of the Bureau. In a similar manner, Mr. Wiley was also retained by the City of Los Angeles to investigate the safety of thirty-two dams.

Mr. Wiley's death ends an exceptionally brilliant engineering career. It deprives the United States Government and many large organizations throughout the world of a Consultant who was highly valued. He held the highest respect of all who knew him. During his fifty years in the West, he made a host of intimate friendships, especially among his engineering associates and others who were connected with his many successful and monumental engineering projects.

His professional counsel will be keenly missed by many organizations. His qualities of mind, his sterling character, and his lovable and winsome nature endeared him to a wide circle of friends and associates who sincerely mourn his passing and in whose memory he will always live.

He was suddenly stricken with the illness that caused his death while engaged on a Consulting Board considering the San Gabriel Canyon development of the Los Angeles County Flood Control District in California. The remaining members of the Board, L. C. Hill, M. Am. Soc. C. E., and Messrs. Robert T. Hill, and C. F. Lohman, in their report, stated:

> "We fellow members of the Board are sincerely grateful that we had the benefit of his [Mr. Wiley's] association on the work and deeply feel his unexpected loss."

The reports from those who knew Mr. Wiley well in the years of his youth and early manhood show that he then possessed the same admirable traits of character and lovable nature that distinguished him in later life. As a young boy entering Newark Academy, and while attending Delaware College, he made his home with Dr. Henry, of Newark, Del., who previously was one of his school teachers. Mr. Wiley worked in Dr. Henry's drug store in return for his living and school expenses. His relation to the Henry family then and throughout his life was that of a devoted and generous son and brother. Dr. Henry's daughter, now Mrs. Edna Henry Cooper, of Wilmington, Del., tells of many delightfully characteristic incidents of young Wiley's life and of his great devotion to her widowed and invalid mother.

Mr. Wiley never married, but he loved children—girls more than boys—and especially during the earlier years of his life in Boise there were established many beautiful friendships which continued to his death. To be a member of "Mr. Wiley's Set" was assurance of seeing all the circuses and best shows, not to mention birthday and Christmas parties, all personally conducted. Initiation into this happy circle generally occurred during the early doll days and the years of beautiful friendships were marked by birthday and Christmas gifts and, in many cases, wedding gifts as the years passed. All these children cherished his friendship to mature years and some of them owed their college education to his generosity. The principal benefactors of his estate were these young friends who had known him from their childhood days.

Mr. Wiley was averse to publicity and seldom spoke before the public, even during meetings of his own Engineering Profession. He enjoyed the companionship of friends and was always a genial and entertaining host. His kindness and consideration of others engendered the loyalty and diligence of his associates. He was always ready to assist his friends in time of trouble.

He loved his work and devoted practically all his time to engineering matters. His intense and untiring studies probably accounted for his unusual capacity for handling details. He never wished to undertake more work than he could personally supervise and often declined to accept professional engagements because of his inability to give the work his personal attention.

There follow a few characteristic quotations from letters that have been received from some of Mr. Wiley's friends and associates:

Mrs. Edna Henry Cooper, of Wilmington, Del.:

> "We do not understand why such good useful men are taken in the midst of their precious, busy lives. His work was his great love—so often he has written mother that work was recreation to him and it was just so in his

college days—it was his keen delight to help his classmates who had not the ability he possessed. The years did not change his modest, charming personality."

Mr. J. H. Lowell, of the Gem Irrigation District, Homedale, Idaho:

"It was as a friend that I knew him, retiring, thoughtfully considerate, a most delightful companion. His estimate of people might be whimsical or humorous, never unkindly. A man who always looked for the best in others and who was intensely loyal to friends and associates. * * * Whether as a business associate or as a friend Mr. Wiley inspired confidence, loyalty, and love."

Charles H. Paul, M. Am. Soc. C. E.:

"His kindly disposition which was so apparent to all who knew him; his consideration for the comfort of others; his open-minded regard for others' points of view; his absolute integrity, including his abhorrence of sham or pretence and his hatred of deception or misrepresentation; his sound judgment and common sense; his fine sense of humor; and the high regard accorded him without exception by his clients and associates."

Louis C. Hill, M. Am. Soc. C. E.:

"There was never another man with whom I have served on boards whose opinion merited and received such consideration as did the opinions so modestly and considerately expressed by Mr. Wiley. * * * During the long years of frequent contact with Mr. Wiley, I was always impressed with his modesty, unselfishness, and consideration for others. A great man and a most lovable friend has passed on."

Major John S. Butler, U. S. A., M. Am. Soc. C. E.:

"I was very much impressed with Mr. Wiley's earnest desire to get at the truth of a question; with his wide fund of engineering knowledge along broadest lines, which was always so readily available; with his sound judgment and, notwithstanding a certain firmness of manner, with his gentleness and courtesy to all."

Mr. Frederick Irwin, of San Francisco, Calif.:

"I was never associated with another man who was so uniformly kind and courteous, in all his contacts, and one of whom I was so proud to call my friend."

R. E. Shepherd, Manager of Twin Falls North Side Land and Water Company:

"Death found him at the head of his profession, honored and beloved by all who knew him."

Mr. Otto P. Cherdron, of Salt Lake City, Utah:

"What a pity it seems, that a mind such as this great engineer had, cannot be endowed to some one else. What an accumulation of experiences has been lost which has to be laboriously gathered by other kindred minds."

D. C. Henny, M. Am. Soc. C. E.:

"Mr. Wiley's associates loved him for his unselfish nature, his open-mindedness, his almost excessive modesty, and his constant geniality. The description of a great predecessor (Alfred Noble) may be truthfully applied to Andrew Jackson Wiley: 'An upright man, a good citizen, an eminent engineer, whose life and labors contributed greatly to the high honor of his profession and to the success of many important public works.'"

D. W. Ross, M. Am. Soc. C. E.:

"Mr. Wiley belonged to no religious organization nor did he openly subscribe to any creed, but he gave liberally to every good cause, and like coin of the realm, it seemed always to be taken for granted that he was just as sound as he appeared to be. He truly loved his neighbor as himself. But his 'neighbor' was not the one who had *given* assistance, but the unfortunate one who was in need of help. He had a remarkably keen sense of humor and was the life of every small company of friends, but shunned the limelight, and never found it difficult to put the time in happily and profitably when alone. The greatest engineering works, the dams which he helped to plan and construct, if arranged end to end would extend for many miles and their continuous profile would make a most imposing skyline—fitting monuments to his great engineering skill. But greater than these works was their designer, this quiet, unassuming, smiling gentleman, who cared neither for riches nor fame and who had such a big place in his heart for children and dogs. It can be truly said of him that 'his reward was with him and his work before him.'"

Mr. Wiley was elected a Member of the American Society of Civil Engineers on December 5, 1894.

HENRY DICKINSON WOODS, M. Am. Soc. C. E.[1]

DIED APRIL 2, 1931

Henry Dickinson Woods was born in Paris, France, on October 3, 1852, the son of Henry Woods and Annie L. (Dickinson) Woods. His father was long a member of the old-time firm of C. F. Hovey and Company, representing that house in Europe and making his home in Paris for thirty years. It was his custom to return to the United States at least once every four years in order, as an American citizen, to vote in the National elections. It was in Paris, therefore, that his son, Henry Dickinson Woods spent his boyhood and received most of his education, with an interval of two years in 1866 and 1867 when he came to this country and attended a boarding school at Newport, R. I. In Paris, he attended the College Chaptal and, later, the Ecole Centrale des Arts et Manufactures, from which he was graduated in 1875.

After his graduation Mr. Woods came to the United States and spent his first two years in this country as a Draftsman and Rodman on the Dam Division of the Boston, Mass., Water-Works. He then returned to Paris and spent a part of the next year in association with Eduard Badoit, Civil Engineer, on plans for the St. Louis, Senégal, Water-Works. He spent the year, 1879, working with Mr. H. T. Bartlett, in Paris, on board-cutting machinery, and, in 1880, he again returned to the United States to accept a position as Assistant in the office of the City Engineer of Newton, Mass., which position he retained until 1884. During his four years as an Assistant Engineer, Mr. Woods was engaged in general municipal work, highways, heating and ventilating school-houses, and alterations to the City Hall and other municipal buildings. He spent the year, 1884, in traveling between France, Belgium, and England, in the interest of the Carson Trench Machine Company.

---

[1] Memoir prepared by William P. Morse, M. Am. Soc. C. E.

In the latter part of 1884 Mr. Woods engaged in the private practice of surveying and building construction, remaining in this business until the latter part of 1887. At that time he gave up his practice to accept a position in the office of the Chief Engineer of the Massachusetts State Board of Health, to work on investigations relative to the various water supplies of the State and the question of sewerage purification abroad. After leaving the Massachusetts State Board of Health, he was employed for a year as Inspector of Masonry Foundations for bridge work for the City of Newton and the Town of Wellesley, Mass.

In 1889, Mr. Woods again returned to Europe as "Ingénieur Expert" with the United States Commission, Paris Exposition, coming back in 1890 to the office of the City Engineer of Newton, as Principal Assistant. In 1893, he was appointed City Engineer, in which capacity he remained until January 13, 1900. At that time he retired from the Engineering Profession and began the work which he so loved among his greenhouses, on the hill close to his home.

In his six years as City Engineer, the position he filled so well because of his education and wide experience in the various lines of engineering, both in the United States and abroad, Mr. Woods accomplished a great deal for the fast-growing City of Newton. The Commonwealth Avenue Boulevard, constructed to a width of 120 ft. through the center of the city, was completed during his administration.

Because of many fatal accidents it became necessary to abolish the grade crossings along the main line of the Boston and Albany Railroad, and to widen Washington Street to 75 ft. It was during the years that Mr. Woods was City Engineer that this great engineering feat was accomplished, which included the widening of Tremont and Park Streets and the reconstruction of many main drains along the line of the railroad. During his administration, Bulloughs Pond, which had formerly been a municipal eyesore, was also changed, and is to-day a beauty spot, in the center of the city.

In 1899, studies and negotiations were made with the Boston and Albany Railroad Company and plans were drawn for the abolition of the grade crossings on the south side of the city. Before this work was definitely started, however, Mr. Woods retired from his position as City Engineer, leaving behind him many treasured friends and lasting monuments of work which he had created during the time of his association with the City of Newton.

He was greatly interested in charities all over the world and contributed liberally to a large number. During and after the World War he was especially interested in the Phare de France, for the re-education of men blinded in the war, and also in the Preventorium, a charitable health center for children established by the Lafayette Association at Chavagnac, France, to which he gave a refectory building. His generosity was well known and in his will he made bequests to many charities which he had supported during his life, among which were: The New England Home for Deaf Mutes; Massachusetts Association for Promoting Interests of Adult Blind; New England Peabody Home for Crippled Children; Industrial School for Crippled and Deformed Children; Infants' Hospital; Bethesda Society; Boston Floating Hospital; Boston Society of Natural History; New England Moral Reform Society; Massachusetts Charitable Eye and Ear Infirmary; Stone Institute and Newton Home for Aged People; and, Prentiss Normal and Industrial Institute, Prentiss, Miss.

Mr. Woods was a member of the Boston Society of Civil Engineers, the New England Water Works Association, and the Massachusetts Genealogical Society.

He was married, in 1894, to Jennie A. Pond, of Brookfield, Mass. He is survived by one daughter, Mrs. Ethel P. Coty, and two grandchildren.

Mr. Woods was elected an Associate Member of the American Society of Civil Engineers on March 1, 1893, and a Member on June 5, 1895.

CHARLES WORTHINGTON, M. Am. Soc. C. E.[1]

DIED AUGUST 29, 1931

Charles Worthington, the son of Edward and Carolina C. (McLean) Worthington, was born in Worthington Valley, Baltimore County, Maryland, on May 12, 1871.

His early education was received entirely at home until the fall of 1888 when he entered Rensselaer Polytechnic Institute, at Troy, N. Y., from which he was graduated in June, 1892, with the degree of Civil Engineer.

Mr. Worthington's first position was that of Draftsman for the Maryland Steel Company, of Sparrows Point, Md., which he held during July, 1892. From August to September of the same year, he served as Draftsman for the Link Belt Engineering Company, of Philadelphia, Pa., and from October, 1892, until June, 1894, he was Instructor in Civil Engineering at the University of Pennsylvania, at Philadelphia.

Subsequently, Mr. Worthington held the following positions: From July, 1894, to January, 1895, as Draftsman, making shop drawings, with the Keystone Bridge Works, at Pittsburgh, Pa.; from the latter date until December, 1895, as Draftsman and Estimator with the Phoenix Bridge Company, at Phoenixville, Pa.; from December, 1895, to July, 1896, as Bridge Engineer in the Maintenance-of-Way Department, reporting on the strength of old structures, etc., of the Pennsylvania Railroad Company, at Philadelphia; from July, 1896, to January, 1897, in the Estimating Department of the Pennsylvania Steel Company at Steelton, Pa., making designs and estimates of various kinds of structures, principally railroad and highway bridges; from January to July, 1897, as Resident Engineer and Inspector on the erection of the superstructure of the Duluth-Superior Bridge (one 500-ft. draw and two 300-ft. approach spans) under the late Alfred P. Boller, M. Am. Soc. C. E., Chief Engineer; from July, 1897, to July, 1899, in the Estimating Department of the Keystone Bridge Works, making designs and estimates of steel structures of all kinds, including the following: One 450-ft. and two 300-ft. deck spans of the Allegheny and Western Railroad Bridge over the Allegheny River at Mosgrove, Pa.; two viaducts, 100 ft. high and about 400 ft. long, for the same Railroad Company; design for a cantilever bridge, 1 600 ft. long, center to center, river piers, and two 600-ft., center to center, anchor piers over the St. Lawrence River, at Quebec, Que., Canada, including estimate of material, as well as many other railroad and highway bridges, mill buildings, etc.; during August, 1899, with Brown Hoisting and Conveying Machine Company, at Cleveland, Ohio; from September to October, 1899, with Wilkins and Davison, Engineers, of Pittsburgh, on the design of several steel viaducts for a street railway and a cantilever bridge for a city street; and from November, 1899, to May, 1900, with the Keystone Bridge Works, in charge of designing and detailing several mill buildings and plate-girder bridges.

---

[1] Memoir prepared from information on file at the Headquarters of the Society.

For the next ten years, Mr. Worthington was in private practice as Consulting Engineer in Pittsburgh and New York, N. Y. During this time, he designed and superintended the erection of a coal plant for the Virginia and Pittsburgh Coal and Coke Company, near Fairmont, W. Va., which cost about $40 000. Other work included the design of bridges, mill buildings, steel frames for office buildings, etc.

Some of the later engagements of Mr. Worthington were: The design of all steel work for the Carnegie Library at Pittsburgh, costing about $5 000 000; the design and supervision of construction of the steel work for the Municipal Ferry Terminals at the foot of Whitehall Street, costing about $1 100 000, and also for the new 22d Regiment Armory at West 168th Street, both in New York City; the design and construction of a composite building (of reinforced concrete and structural steel) to serve as a covered tennis court on a private estate near New York, for Warren and Wetmore, Architects, costing about $150 000; the design of a number of buildings of the mill type for the Aluminum Company of America; and the design of all bridges for the Little Falls and Johnstown Railroad Company, and many other structures.

From September, 1914, until April, 1915, Mr. Worthington was engaged as Contracting and General Engineer for the Columbus Mill and Mine Company, of Columbus, Ohio, and from April, 1915, until February, 1917, he was Designer and Estimator for Milliken Brothers, of New York City.

In February, 1917, Mr. Worthington received the appointment of Civil Engineer in the United States Navy, at Washington, D. C., where he remained until April, 1920, leaving to accept a position with Stone and Webster, Incorporated, in Boston, Mass.

On account of ill health, in November, 1929, Mr. Worthington severed his connection with Stone and Webster, Incorporated, and went to Florida where he resided until his death.

He was married in 1906 to Fannie A. Crumpton, of Pittsburgh, who, with a son, Charles C. Worthington, survives him. A daughter, Elizabeth C. Worthington, died in July, 1930.

Mr. Worthington was elected a Member of the American Society of Civil Engineers on November 6, 1901.

ADOLPH YAPPEN, M. Am. Soc. C. E.[1]

DIED APRIL 4, 1931

Adolph Yappen was born on the Island of Fehmern, Denmark, on November 5, 1860, the son of Richard N. and Caroline Yappen. In 1867, the family emigrated to the United States and settled at Sabula, Iowa, and it was there that Mr. Yappen's boyhood was spent and there that he received his public school education. Possessed of a roving disposition, he went to the Pacific Coast when he was only fifteen years old and, later, entered the University of California, working his way through college, from which he was graduated in June, 1882.

On leaving college, Mr. Yappen secured a position with the Northern Pacific Railroad Company as Rodman on new construction, subsequently being promoted to Instrumentman and Assistant Engineer, working under Mr. Bogan who, at that time, was Principal Assistant Engineer.

Mr. Yappen's experience after leaving the employ of the Northern Pacific Railroad Company can best be told in his own words:

> "I was what might well be called a tramp engineer—worked as Instrumentman on the jetty work at the mouth of the Columbia River. Later, I find I was on a survey between Antioch and Bakersfield, Calif., now a part of the Southern Pacific. At that time it was the San Joaquin and Kern Valley Railway. Later, on a location of a proposed road in Mexico. Later, with a Government survey through Ecuador over the Andes through part of Brazil and from south to north through Venezuela. At one time went to Panama as Assistant Engineer when the French were trying to dig the ditch, but got disgusted and went back to Oregon, and also visited the Alaska gold field at the junction of the Yukon and Stewart Rivers."

Among other work during this period, he assisted in laying out the City of Tacoma, Wash.

In 1893, Mr. Yappen entered the Bridge and Building Department of the Chicago, Milwaukee and St. Paul Railway Company and remained in its service and that of its successor, the Chicago, Milwaukee, St. Paul and Pacific Railroad Company, until his death.

In 1898, he was on the staff of W. A. Rogers, M. Am. Soc. C. E., at that time Engineer of Subways on the first Chicago Track Elevation work undertaken by the Railway Company and, later, he served as Assistant Engineer on masonry construction and on bridge work in Illinois, Iowa, and Missouri. In 1901, he became District Carpenter, with headquarters, successively, at Green Bay, and Milwaukee, Wis., and Chicago, Ill. In 1919, he was made Assistant

---

[1] Memoir prepared by T. L. D. Hadwen and Walter A. Rogers, Members, Am. Soc. C. E.

Engineer of Bridge Maintenance on the System, which position he occupied until his death.

Mr. Yappen showed in his massive physique, which stood him in such good stead in his early wanderings, the traces of his Viking ancestry and, in his character, the persistent determination to achieve correct results, of his Teuton forebears. Quiet and unassuming in manner and highly conscientious, he possessed a sense of humor and a tolerance which made him very successful in handling men. His wide experience and sound judgment were always at the service of his friends. He had a fondness for mathematical problems and found recreation in their solution. His early experience in pioneer construction had given him a fund of knowledge on timber construction, which few possess.

He was a member of the Western Society of Engineers, and of the American Railway Bridge and Building Association. He was also a member of various Masonic bodies.

In 1909, he was married to Belle Paul, of Viroqua, Wis., who, with his younger brother, Reinhart Yappen, of Rock Rapids, Iowa, and a number of nieces and nephews, survives him.

Mr. Yappen was elected an Associate Member of the American Society of Civil Engineers on June 1, 1909, and a Member on July 7, 1915.

ELMER ZARBELL, M. Am. Soc. C. E.[1]

DIED SEPTEMBER 10, 1931

Elmer Zarbell, the son of Iver C. and Pauline (Hane) Zarbell, was born in Chicago, Ill., on May 25, 1874. His education was obtained in the public schools of Chicago and at Cornell University, Ithaca, N. Y. He was graduated from the latter institution in the Class of 1895, with the degree of Civil Engineer.

Immediately on the completion of his college course, Mr. Zarbell went to Harrisonburg, Va., where, until January, 1897, he held a position as Draftsman and Assistant Engineer with the Chesapeake and Western Railroad Company. In this position, his duties were general, in connection with the construction of twenty-seven miles of railroad and several hundred miles of surveys.

In January, 1897, he became associated with the Mobile and Ohio Railroad Company as Instrumentman, on preliminary and location surveys in Bibb County, Alabama; somewhat later he was made Assistant to the Resident Engineer in charge of construction of the Mobile and Ohio Railroad Bridge across the Alabama River, at Montgomery, Ala., and, during the early part of 1898, acted as Resident Engineer in charge of the construction of yards and terminals for the Mobile and Ohio Railroad Company at Montgomery.

Mr. Zarbell served during the Spanish-American War from August, 1898, to March, 1899, as Second Lieutenant with the Third Regiment, U. S. Volunteer Engineers, at Jefferson Barracks, Missouri; as First Lieutenant, at Lexington, Ky. and Macon, Ga.; and as Adjutant of the Third Battalion, at Matanzas, Cuba, and Atlanta, Ga. He was in charge of various harbor improvements, made in Cuba, and commanded an expedition, including a squad of the Second U. S. Cavalry, making a reconnoissance of half of Matanzas Province.

---

[1] Memoir prepared by G. R. Smiley, Assoc. M. Am. Soc. C. E.

From March, 1899, until March, 1900, Mr. Zarbell was with the Special Commission on the Chicago Drainage Canal, at Chicago, in charge of re-measurements and re-calculations for capacity, velocity, etc.

He became associated with the Engineering Department of the Louisville and Nashville Railroad Company in March, 1900, and, thereafter, until the time of his death, he was engaged on the maintenance, construction, and design of important lines and projects for that Company. For a year subsequent to 1900, he served as Assistant Engineer in charge of the construction of the Camden Branch. From March, 1901, to January, 1903, he was Resident Engineer in charge of the construction of the Alabama River Bridge and eight miles of roadbed at Selma, Ala. From January to March, 1903, he was Assistant Engineer at Pennsacola, Fla. During the remainder of that year, he was in charge of the field surveys then being made for reduction of grades and elimination of curvature on the Henderson Division.

In January, 1904, Mr. Zarbell was appointed Engineer of Maintenance of Way of the Alabama Mineral Division, in which position he remained until August, 1905. At this time he was transferred to Louisville, Ky., as a General Assistant to the Chief Engineer, where he had charge of the design and general supervision of the Company's concrete structures of all types as well as assisting generally in the administrative work of the office.

Impeccable in character, Mr. Zarbell was a man of positive characteristics. He was intolerant of anything that was wrong, and drove direct to the conclusion that in his judgment was correct. Absolutely loyal, he was indefatigable in his attention to all work he had in charge. He mastered the details of each problem and overcame its difficulties. Because of his qualities his friendship will be remembered long and appreciated deeply.

He was married on October 12, 1904, to Fay Smith, of Denver, Colo., who, with a son, Iver, and a daughter, Dorathea, survives him.

Mr. Zarbell was elected a Junior of the American Society of Civil Engineers on January 3, 1899; an Associate Member on February 7, 1900; and a Member on May 5, 1908.

JULIAN WILMOT ALGER, Assoc. M. Am. Soc. C. E.[1]

DIED JANUARY 27, 1932

Julian Wilmot Alger, the only son of Wilmot R. and Carrie (Tomlinson) Alger, was born in Stowe, Vt., on October 27, 1890. He was graduated from Norwich University, at Northfield, Vt., in 1910, with the degree of Bachelor of Science in Civil Engineering.

---

[1] Memoir prepared by Henry C. Porter, M. Am. Soc. C. E.

Mr. Alger received his first engineering experience on water-power and municipal investigation work at Wells River, Vt. However, most of his active professional life was spent in Texas to which State he removed in 1911. At that time he accepted a position with the San Benito Land and Water Company, San Benito, Tex., and during the next six years he was engaged upon the following engineering projects in Texas: The construction of the Medina Lake Dam, near San Antonio; with the United States Engineering Department, on surveys of the Guadalupe River; with the San Benito and Rio Grande Valley Railway Company; the American Rio Grande Land and Irrigation Company, of Mercedes; and the United States Engineering Department, at Galveston.

In 1917, Mr. Alger entered the First Officers' Training School for the United States National Army, at Leon Springs, Tex.; he finished the Engineer Officers' Training School at Fort Leavenworth, Kansas, on August 15, 1917, received a commission as First Lieutenant, and was assigned to the 315th Engineer Regiment, 90th Division, of the United States Army. Upon his arrival at Camp Travis, Texas, he was assigned to C Company, and, in France, he commanded C Company, with the rank of First Lieutenant, during its entire seventy-four days of service at the front in the St. Mihiel and the Meuse-Argonne Offensives. He received a citation for seventy-three hours of duty without rest or sleep during that time.

On April 28, 1919, he was commissioned Captain of Engineers. In the latter part of May of that year, he was appointed Personnel Adjutant of the 315th Engineer Regiment, and, a few days later, was made Regimental Adjutant, serving in that capacity until his organization was mustered out of service on June 26, 1919. He was honorably discharged on July 12, 1919.

In 1920, Mr. Alger was Field Construction Engineer with American Dreseler Tunnel Kilns, Incorporated, of Cleveland, Ohio, and, in 1921, he was with the Valuation Department of the St. Louis and San Francisco Railway Company, engaged in computing and compiling data. Later, he served as Computer and Estimator in the City Engineer's Office of Dallas, Tex., on street paving. In 1922, Mr. Alger was employed by Sutton County, Texas, to locate, design, and construct State highways in that County, with State and Federal Aid. In October, 1923, he was made County Highway Engineer of Dickens County, Texas, on the location, preparation of plans, and construction of State highways in that County until the completion thereof in December, 1926. From January to April, 1927, he was employed by the State Highway Department as Resident Engineer for Lubbock County, Texas, on plans and construction of State highways, and from April to October, 1927, he brought to completion, as Resident Engineer for the State Highway Department at Breckenridge, Tex., the State highway program in Stephens County. In November, 1927, he was appointed Resident Engineer of Navarro County, for the State Highway Department, at Corsicana, Tex., on the location, preparation of plans, and construction of State highways in that County, which work was not completed at his death on January 27, 1932.

Mr. Alger's illness was of short duration, and his death came as a great shock to his loved ones and to a wide circle of friends in Texas and elsewhere.

A man of simple and temperate habits in all things, it was expected that a long and useful future stretched before him. Well-trained, capable, thorough, and conscientious in his work, his career as a Civil Engineer will always reflect honor upon his name and upon the profession to which he belonged; widely read and well informed on all subjects, he was a most delightful and interesting conversationalist; cheerful and optimistic by nature, daily association with him in his work and elsewhere was most congenial and pleasant; possessed of a high sense of honor, he expected and demanded the same honesty from those with whom he dealt; holding himself aloof from the petty, inconsequential things about him, he seemed to dwell serenely and thoughtfully in an atmosphere all his own, to which he welcomed his friends with all the kindliness, consideration, and cordiality of the loyal friend he was. Honest citizen, painstaking workman, fearless soldier, firm but just executive, and cultured gentleman, Texas has lost much in the passing of Julian Wilmot Alger.

Immediately after his return from France, Mr. Alger was married, on July 15, 1919, to Margaret Bushwall, who survives him, and with his many friends mourns his passing.

Mr. Alger was elected an Associate Member of the American Society of Civil Engineers on March 16, 1925.

ALBERT ROSS BAILEY, Assoc. M. Am. Soc. C. E.[1]

DIED JUNE 29, 1931

Albert Ross Bailey was born in Grand Rapids, Mich., on February 28, 1877. He was the son of Charles and (Susan) Bailey, who had moved to Michigan from the State of New Hampshire.

Mr. Bailey was educated in the public schools and at the University of Michigan where from 1899 to 1903 he was a student in the Engineering College. He returned to the University in 1909 as an Instructor in Surveying and Drawing and, in 1913, received the degree of Bachelor of Arts.

From 1903 to 1909, he was employed by the Engineering Departments of the New York Central and Baltimore and Ohio Railway Companies, on construction work and also in the office as Draftsman and Chief Draftsman

From 1909 to 1914, he served on the Faculty of the University of Michigan as Instructor in Surveying and Drawing, and, from 1914 to 1917, as Assistant Professor in Civil Engineering, teaching Railway Engineering.

During his University service, he was employed by Mortimer E. Cooley, M. Am. Soc. C. E., in connection with valuations of the Pere Marquette Railroad and the Detroit United Railroad. He received a leave of absence for the last year of his connection with the University and was engaged on the valuation of the Public Service Railways of New Jersey, associated with Dean Cooley and Mr. H. C. Anderson.

---

[1] Memoir prepared by a Committee consisting of Henry E. Riggs and W. C. Hoad, Members, Am. Soc. C. E.

From 1917 to 1920, Mr. Bailey was Engineering Assistant to the General Valuation Counsel of the New York Central Lines, with headquarters in New York, N. Y., devoting his time to the study of questions of valuation theory and making investigations and reports on railway construction throughout the eastern half of the United States.

In 1920, he returned to Ann Arbor, Mich., and associated himself with Mr. H. H. Atwell in engineering and construction work, under the firm name of Bailey and Atwell. This partnership continued until 1922, during which time the firm was engaged in the construction of bridges and roads in Southeastern Michigan.

In 1922, Mr. Bailey was appointed Engineer-Manager of the Washtenaw County Road Commission and was placed in charge of all highway activities in the County, which position he held at the time of his death. He had the responsibility for all construction and maintenance of roads, county parks, and parkways. He established the accounting and statistical records of the Highway Department on the highest plane. He designed and built the larger part of the present permanent roads of the County. He conceived and carried to completion the construction of the Huron River Drive, a parkway extending for nine miles along the Valley of the Huron River, from Ann Arbor to Dexter, Mich. This was one of the pioneer high-class parkway developments in the State. During his administration, approximately 300 miles of paved highways and gravel roads were built in the County, and considerable construction work was done in landscaping and planting.

Throughout Mr. Bailey's connection with the work of the Washtenaw County Highway Commission, he gave special attention to the scenic development of highways and parkways and had a very keen sense of the value of this class of improvement to the people. His untimely death just at the commencement of the finer and more artistic highway development in Eastern Michigan is a real loss to the community.

Mr. Bailey's annual reports have been among the most complete and comprehensive of any of the County reports and have set a high standard for other counties in Michigan.

He was a member and Director of the Ann Arbor Chamber of Commerce, and a Director of the Ann Arbor Flying Club, in which connection he was responsible to a large degree for the airport development in the County.

Mr. Bailey was a competent and skillful engineer, a man who was thoroughly engrossed in his work, a good citizen, and a good public servant. His outstanding qualities were his gentleness of nature and his loyalty to his friends. He made a large place for himself in Ann Arbor and in Michigan.

Mr. Bailey's death resulted from injuries received in an automobile accident while going to his work, and was directly due to his attempt to avoid injury to a runaway team.

On April 6, 1905, he was married to Effie Reid, of Battle Creek, Mich. He is survived by his widow, a daughter, Virginia, and a son, Reid.

Mr. Bailey was elected an Associate Member of the American Society of Civil Engineers on July 2, 1913.

GEORGE CASTLEMAN BRECKINRIDGE, Assoc. M. Am. Soc. C. E.[1]

Died April 26, 1932

George Castleman Breckinridge was born in Huntsville, Mo., on January 16, 1885, the son of John and Nellie Breckinridge. His father was a Civil and Mining Engineer and his grandfather was Judge S. M. Breckinridge, of St. Louis, Mo. He was a nephew of Onward Bates, Past-President and Hon. M. Am. Soc. C. E., of Chicago, Ill., noted Civil Engineer.

In 1903 he entered the Missouri School of Mines, but transferred to the University of Missouri the second semester of 1904-05, finishing that term and the following summer session. In 1915, he re-entered the University of Missouri and continued his studies with interruptions until 1917.

Mr. Breckinridge began his professional career as Assistant Surveyor and Mine Foreman for the Illinois Jalisco Copper Mining Company, at Ayutla, Mexico, in July, 1902, continuing in this capacity until he entered the Missouri School of Mines in the fall of 1903.

Upon leaving school in 1905, he entered the City Engineer's Office at Joplin, Mo., as Rodman and Chainman. In February, 1906, he engaged in private practice in Pittsburg, Kans., his work consisting largely of surveying and mapping for coal mines in the district.

In November, 1906, Mr. Breckinridge returned to Mexico as Mine Foreman for the Mexican Coal and Coke Company, at Las Esperanzas, and in June, 1907, became Engineer in charge of three mines for the Compania Carbonifera de Monterey, at El Menor. He returned to Huntsville, Mo., in August, 1908, in the capacity of Engineer for the Northern Central Coal Company, taking care of three mines at Huntsville and Higbee, Mo. He also managed his mother's farm during this period.

In September, 1911, Mr. Breckinridge entered the employ of the Manufacturers Railway at St. Louis, Mo., and was engaged in the reconstruction of switching yards, roundhouses, shops, and track work. In August, 1912, he joined the staff of the St. Louis Engineer's Office of the Chicago, Burlington and Quincy Railroad Company and continued with that organization until June, 1914, principally on double-track construction work. Following this, he was with the Southern Railway Company and the Wabash Railway Company, both at St. Louis, engaged in construction, valuation, and maintenance-of-way work.

In August, 1915, Mr. Breckinridge became Resident Engineer on bridge construction for the Illinois State Highway Commission. Returning to the University of Missouri in the fall of 1915, he continued his studies and also served as Assistant City Engineer of Columbia, Mo., while attending the University. In May, 1917, he returned to railroad work with the Missouri Pacific Railroad Company, at Omaha, Nebr., on track elevation.

In March, 1918, he became Chief Engineer of the Bell and Zoller Coal and Mining Company and, later, was appointed Superintendent of that

---

[1] Memoir prepared by William von Meding, Esq., Chicago, Ill.

Company's No. 2 Mine at Zeigler, Ill., continuing in this position until July, 1919, when he resigned to become Superintendent of Mine 27 of the Peabody Coal Company, at Shelburn, Ind. He served in this capacity until he was transferred to Bellwood, W. Va., in May, 1928, as Superintendent of Mine 71, owned by the Bellwood Coal Company, a subsidiary of the Peabody Coal Company.

In February, 1929, Mr. Breckinridge again returned to railroad work with Walter A. Shaw, M. Am. Soc. C. E., of Chicago, Ill., in connection with grade separation in the North Shore suburbs. While engaged in this work he became interested in developments in the Soviet Union and accepted a position as Senior Mining Engineer with the Commission sent to Siberia by Allen and Garcia Company, of Chicago. He left Chicago in the latter part of March, 1930, arriving in Tomsk, Siberia, on April 18. His work was mostly of a consulting nature, in connection with the development of the major Siberian fields. He traveled extensively through the various mining districts and planned several large operations, chiefly in the Cheremhovo Basin. In October, 1931, this work was terminated, and the Commission, as a whole, returned to America.

Mr. Breckinridge, however, in company with two others, chose to remain and continue as individuals, concluding a separate contract with the Soviet Coal Trust known as Vostugol. He became District Engineer of the Prokopievsk Field, and continued as such until March 1, 1932. In returning, he contracted a severe cold at Tiaga, Siberia, a junction point on the Trans-Siberian Railway, and arrived in Berlin, Germany, suffering from pleurisy. In spite of the best care of Berlin physicians, Mr. Breckinridge contracted pneumonia and died on April 26, 1932.

He was married in Joplin, Mo., on September 11, 1905, to Pearl Coles, who survives him. He was the father of Albert C., John, George C (deceased), and Virginia.

Mr. Breckinridge was a member of Shelburn, Ind., Lodge No. 369, A. F. and A. M., Jerusalem Chapter No. 81, Royal Arch Masons, Sullivan, Ind., and Zorah Shrine Temple, of Terre Haute, Ind.

He was a Registered Civil and Mining Engineer in the State of Indiana, and a member of the American Institute of Mining and Metallurgical Engineers.

Mr. Breckinridge was elected an Associate Member of the American Society of Civil Engineers on February 24, 1924.

MORTON BURDEN, Assoc. M. Am. Soc. C. E.[1]

DIED APRIL 15, 1931

Morton Burden, the son of John and Jenet (Duncanson) Burden, of Stirling, Scotland, was born at Troy, N. Y., on April 13, 1874. His parents were married in Stirling and came to America a few years later. For a short period his father was connected with the Burden Iron Works in Troy.

---

[1] Memoir prepared by Richard Khuen, Jr., M. Am. Soc. C. E.

Mr. Burden studied civil engineering at the Rensselaer Polytechnic Institute, in Troy, and was graduated in 1895. From September of that year to September, 1897, he was in the Bridge and Construction Office of the Pencoyd Iron Works, and from September, 1897, to November, 1898, he was in the Drafting Office of the Keystone Bridge Works, making and checking shop drawings of bridges and buildings.

In November, 1898, Mr. Burden entered the Engineering Office of the Ohio Steel Company (now a part of the United States Steel Corporation), where he served as Chief Draftsman of the Structural Department, designing the buildings and other structural work required for the various plants, including the ore, coke, and limestone bins and trestles for the four large blast furnaces which were built at the Ohio, New Castle, and Mingo Works.

In 1901, Mr. Burden became connected with the American Bridge Company in the Designing Department, at Pittsburgh, Pa., making designs and estimates of various classes of structural steel work, including the design of such structures as pipe mills and steel plant buildings for the National Tube Company, at Lorain, Ohio; pipe mills at McKeesport, Pa.; a steel plant for the Brier Hill Steel Company, at Youngstown, Ohio; buildings for the American Rolling Mill Company, at Middletown, Ohio; plate and jobbing mills for the Otis Steel Company, at Cleveland, Ohio; factory buildings for the Pittsburgh Plate Glass Company, at Ford City, Pa.; mill buildings for the Pittsburgh Crucible Steel Company, at Midland, Pa.; a 16-story office building for the Eastman Kodak Company, at Rochester, N. Y., and numerous other structures. From 1914 to 1926, he was in charge of the Designing and Estimating Office of the Pittsburgh Division.

From 1926, until the time of his death, Mr. Burden was on special assignments of designing and supervising large corporation work, such as new mill buildings for the National Tube Company, at McKeesport; a new seamless mill, at Lorain; a new roof for pipe mills, at McKeesport; a new beam shop for the American Bridge Company, at Ambridge, Pa.; a new warehouse for the Carnegie Steel Company, at Pittsburgh; and a new coal washery, at Clairton, Pa.

To his many friends and business associates Mr. Burden was a pleasant companion, a man of sterling character, and a steady, hard worker. He derived a great deal of pleasure out of working in his garden, but did not indulge in the more strenuous outdoor pastimes.

He was married to Jane Nevin Knox, of Sewickley, Pa., on October 29, 1906. He is survived by his widow and one son, Morton Burden, Jr., a Junior at Dartmouth College, Hanover, N. H.

Mr. Burden died of pneumonia on April 15, 1931, in the Sewickley Valley Hospital. His passing leaves a void in the hearts of many who knew him and who had learned to love him for his personal qualities.

Mr. Burden was elected a Junior of the American Society of Civil Engineers on February 4, 1896, and an Associate Member, on January 2, 1901.

ROBERT MORRIS DRAKE, Assoc. M. Am. Soc. C. E.[1]

Died October 25, 1931

Robert Morris Drake, the son of Colonel J. M. Drake and Angelina (Robb) Drake, was born in Portland, Ore., on April 2, 1869. He entered Leland Stanford University with its pioneer class in 1891, and received the degree of Bachelor of Arts in Civil Engineering in June, 1894.

Previous to entering the University, Mr. Drake had been employed from March to December, 1890, as Leveler on a location survey for the Oregonian Railway Company; from February to July, 1891, on surveys for the Portland Water-Works; and from July to October, 1891, as Leveler on a location party for the Union Pacific Railroad Company. During the summer of 1892, he was engaged as Assistant Engineer with the East Side Railway Company, on the construction of an electric railway connecting Portland and Oregon City, Ore.

Mr. Drake entered the service of the Southern Pacific Company in July, 1895, as an Assistant Engineer in the Maintenance-of-Way Department, and for seven years was engaged in the work of that Department, including new bridges, terminals, changes of alignment, and revision of grades.

In 1902, he was given charge of bridge and building work on the Coast Division, and, in 1906, he was promoted to the position of Division Engineer. In 1907, he became District Engineer, Maintenance of Way, for the Northern District of the Southern Pacific Company, continuing in such office until the time of his retirement in 1918.

Owing to failing sight, Mr. Drake lived very quietly at his home, in San Francisco, Calif., after leaving the railroad service. He died suddenly on October 25, 1931, and his funeral services were conducted by California Lodge No. 1, F. and A. M., of which he was a member.

He was married in San José, Calif., on November 11, 1900, to Caroline Mosher, who survives him.

Mr. Drake was elected an Associate Member of the American Society of Civil Engineers on March 7, 1900.

PRESTON BURT EASTERBROOKS, Assoc. M. Am. Soc. C. E.[2]

Died February 1, 1931

Preston Burt Easterbrooks, the son of Ezra Otis and Nora Barton Easterbrooks, was born in Swansea, Mass., on February 26, 1876. He could be classed among the self-educated since he assumed the duties of his first position before completing his High School course. Soon realizing his limited future without further technical knowledge, he availed himself of the evening engineering courses at The Rhode Island School of Design, and thereafter continued by himself in the higher mathematics, ever increasing and widening his knowledge of his profession.

---

[1] Memoir prepared by W. H. Kirkbride and George W. Rear, Members, Am. Soc. C. E.

[2] Memoir prepared by C. E. Hunt, Affiliate, Am. Soc. C. E.

In 1892, Mr. Easterbrooks entered the service of the New York, New Haven, and Hartford Railroad Company, being employed, successively, as Chainman, Rodman, Draftsman, and Transitman, until January, 1898. Subsequently, he was employed by the Chihuahua and Pacific Railroad Company, as Chief Draftsman and, as such, had charge of the drawing of all plans (except steel), including all masonry plans, used in the construction of 125 miles of road.

He was next engaged by the Chief Engineer of the Mexican Central Railroad Company, City of Mexico, Mexico, and made surveys of betterments in the Corcovada Hills, on the Tampico Branch, and was on reconnaissance with the late J. T. Norton, M. Am. Soc. C. E., from Guadalajara to Aguas Calientes (250 km.). In July, 1900, he was placed in responsible charge of construction on the division covering the Parral Extension, Parral, Mexico. He resigned his position with the Railroad Company in October, 1900, and was associated with the late E. S. Safford, M. Am. Soc. C. E., on surveys for a dam site and increased water supply for the City of Chihuahua, Mexico.

In January, 1901, Mr. Easterbrooks entered the service of the Cuba Company as First Assistant Engineer, and, later, as Superintendent of Construction, Eastern Division, remaining with this Company until June, 1902. During this time he had responsible charge of masonry construction, erection of steel bridges, wooden trestles, track-laying, and material yards.

In July, 1902, he entered the employ of Westinghouse, Church, Kerr, and Company, Engineers, New York, N. Y., and, for eighteen months, served as Chief of Party on the location of the Rochester, Auburn, and Syracuse (N. Y.) Electric Railway. He was next placed in charge of construction of the Scranton Tunnel (4 700 ft. long), as Resident Engineer, for the Lackawanna and Wyoming Valley Railroad Company, at Scranton, Pa. On the completion of this work, he returned to the New York Office of the Company and was engaged on various engineering works, including plans and surveys for electric transmission lines in Northern New York, proposed underground railways for New York City, railway passenger terminals, power developments, etc.

From October, 1911, to May, 1912, he was Chief Assistant Engineer of the Caribbean Construction Company, Port au Prince, Haiti, for which F. W. Andros, M. Am. Soc. C. E., was Chief Engineer. In this capacity, Mr. Easterbrooks was in charge of location and construction work on 100 miles of road under construction and 350 miles contemplated.

In June, 1912, he returned to Westinghouse, Church, Kerr, and Company and was actively engaged on many important engineering projects, including studies for railroad terminals, investigation, and report on an irrigation project in Montana; building hotel and terminal facilities for the Canadian Pacific Railroad Company, at Winnipeg, Man., Canada; constructing difficult foundations for a mole in connection with a large plant development for the Armour Fertilizer Company, at Matanzas, Cuba; and building a sugar refinery having a capacity of 1 000 000 lb. per day, for the Savannah Sugar Refining Company, at Savannah, Ga.

In the spring of 1918, Mr. Easterbrooks was made Construction Engineer of a $25 000 000 contract for the Air Nitrates Corporation, in connection with the Muscle Shoals Development, known as United States Nitrate Plant No. 2. It was the expectation at the time of his assignment to this work that a contract for Plants Nos. 3 and 4 also would be awarded the Company, in which event it was the intention and understanding that Mr. Easterbrooks would be made Resident Engineer in full responsible charge of that project. This opportunity did not materialize, however, and he stayed through the operation of the work on Plant No. 2 and was one of the responsible officials in charge of its construction. It has been written of him that "he did the work to which he was assigned with an enthusiasm and loyalty that was his chief characteristic, putting his shoulder to the wheel where the going was hard and filling in where the ranks were thinnest."

On the completion of this work he returned to New York and was placed in charge of the construction of a plant for the manufacture of complete locomotive superheaters for the Locomotive Superheater Company, at East Chicago, Ill.

During 1919 and 1920, he was Superintendent of Construction on an extensive addition to the plant of the American Rolling Mill Company, at Middletown, Ohio, including warehouse and storage building, galvanizing, finishing, cold-roll distributing furnace, and continuous annealing furnace buildings, sheet mill, fire-bed mill, sewers, roads, track construction, water and fire protection, electrical distribution, boiler-house extension, power-plant addition, spray pond, cooling system, and a large amount of miscellaneous work. The buildings alone covered about 10 acres of ground area.

In 1920, Westinghouse, Church, Kerr, and Company was consolidated with Dwight P. Robinson and Company, Incorporated, and, subsequently, this latter Company was merged with three other prominent engineering organizations, forming the United Engineers and Constructors, Incorporated, and Mr. Easterbrooks was retained by the latter as one of its Superintendents of Construction and, subsequently, was made Construction Manager.

During the next ten-year period, until the time of his death, in addition to his administrative responsibilities, he was in direct charge of the construction of a great variety of projects among which were the Islin Shops at Jackson, Tenn., for the Mobile and Ohio Railroad Company; extensions to the New York, Westchester, and Boston Railway, from Harrison to Rye, and from Rye to Port Chester, N. Y., a two-track electrically operated system, including grading, culverts, fencing, tracks, car lay-up yards, stations and platforms, bridges, tunnels, and stairways, etc. This work was contiguous to the high-tension electrified lines of the New York, New Haven, and Hartford Railroad Company, and was accomplished without interruption or delays to its train service. Mr. Easterbrooks was in charge of the work of extension to the South Street Station of the Narragansett Electric Lighting Company, at Providence, R. I., including switch-house and installation of switching equipment; also, changes and extensions in sub-stations and underground transmission work. He also built the Queensboro Apartments, at Jackson Heights, Long Island, consisting of two groups of seven 5-story elevator apartment houses, containing a total of 140 apartments; the American Embassy at Rio de Janeiro, Brazil; a theatre and office building for the Statler Hotels, in Buffalo, N. Y., and "The Barclay," a high-class fireproof apartment hotel, in Philadelphia, Pa., overlooking Rittenhouse Square.

Mr. Easterbrooks' experience covered a wide range of subjects, and his recognized ability and intimate knowledge of the details which go to make up good construction, on heavy construction as well as on high-class building work, were outstanding characteristics.

He was interested in any young men who came under his direction, who showed promise of future development, and spent a great deal of time in his own way in trying to develop their latent technical ability and to fit them for administrative responsibility.

Personally and professionally, he maintained a high standard of ethics and was unswerving from a course which he believed to be right. Tenacious of purpose, with unflagging energy, he gave himself wholly to his profession and took a justifiable pride in the accomplishment of work well done. Mr. Easterbrooks was a member of Clinton Lodge No. 54, F. and A. M., at Savannah.

He was married in Providence, R. I., on August 9, 1904, to Janet M. Auty, who, with a son, Preston B., Jr., a brother, Frank D. Easterbrooks, and three sisters, Clara B. Easterbrooks, Mrs. Henry J. Peck, and Mrs. Leon H. Read, survives him.

Mr. Easterbrooks was elected an Associate Member of the American Society of Civil Engineers on May 1, 1907.

JAMES HENRY GALLIVAN, Assoc. M. Am. Soc. C. E.[1]

Died February 12, 1931

James Henry Gallivan was born at Northampton, Mass., on September 21, 1876, the son of Patrick and Bridget (Kiley) Gallivan.

After graduating from the Northampton High School, and taking courses in Civil Engineering with the International Correspondence Schools, Scranton, Pa., and the Alexander Hamilton Institute, Poughkeepsie, N. Y., he entered the employ, in 1897, of E. C. and E. E. Davis, Civil Engineers, of Northampton, as a Rodman, continuing with this firm until July, 1902.

---

[1] Memoir prepared by Paul Sterling, M. Am. Soc. C. E.

From April until November, 1898, he served with the 2d Massachusetts Regiment, United States Volunteers, in the Spanish-American War.

In July, 1902, Mr. Gallivan was employed as Transitman with the Metropolitan Water and Sewerage Board of Massachusetts, and in March, 1903, started his railroad career as a Transitman with the Chesapeake and Ohio Railroad Company. In May, 1904, he entered the employ of The New York, New Haven, and Hartford Railroad Company, continuing with that Company, with uninterrupted service, until his death.

Starting as a Transitman, Mr. Gallivan worked his way through the various engineering grades in both the Maintenance and Construction Departments of the Railroad Company. He was appointed Division Engineer of the Central New England Division, at Poughkeepsie, N. Y., in July, 1912. In November, 1917, he was transferred to Boston, Mass., as Division Engineer of the Midland Division, which position he held at the time of his death.

He is survived by his widow and two daughters, Mrs. C. W. Maloney and Mrs. T. B. Gray.

Mr. Gallivan's engineering work was confined almost entirely to railroad new construction and maintenance. The former consisted of double-tracking forty miles of railroad, which involved changing line, modifying grades, and numerous over and under-grade railroad bridges; also, the construction of a large engine terminal yard at Maybrook, N. Y., which included one of the first so-called "hump" yards, with its large supporting receiving, departure, and classification tracks. He had an unusual faculty for handling men, winning their loyalty and support through his always genial personality.

He will be sorely missed by his many personal friends. Full of Irish wit, his stories and personal magnetism always brought him to the leadership of any social gathering. No party was complete without "Jim" Gallivan's presence.

Mr. Gallivan was elected an Associate Member of the American Society of Civil Engineers on January 2, 1912.

JAMES HENDRICKS HALLETT, Assoc. M. Am. Soc. C. E.[1]

DIED JANUARY 11, 1931

James Hendricks Hallett was born in Cambridge, Mass., on September 14, 1874. His father, Nelson Arnold Hallett, was a descendant of distinguished loyalist families that fled from New York in 1783, at the close of the War of the Revolution, and settled in St. John, N. B., Canada. His mother was Jennie Burns (Cunningham) Hallett, whose father, John Cunningham, was a prominent Architect and Civil Engineer for more than half a century in Scotland and America. The boy's early education was completed in the local schools of Cambridge.

---

[1] Memoir prepared from information on file at the Headquarters of the Society.

Mr. Hallett was associated with Hodges and Harriman, Civil and Consulting Engineers, of Boston, Mass., as Rodman, Levelman, and Transitman from 1896 to 1899. There was a year's interlude in this period, during the Spanish-American War, at which time he volunteered and served in the United States Army, in Cuba.

From 1899 to 1903, Mr. Hallett was with Ephraim Harrington and Company, Civil Engineers, of Boston, as Inspector and Superintendent of Construction. At this time the measurements and physical examinations were made for the consolidation of seventy-one street railway companies into the Massachusetts Electric Company. This System included 900 miles of track, with 200 bridges as well as highway construction. He was also engaged on the construction of street railways, pavements, and bridges for the Norwich and New London, Conn., Street Railway Company, the Milford, Attleboro, and Woonsocket, Mass., Street Railway Company, and with companies of many other New England towns in the immediate vicinity.

In 1904, Mr. Hallett entered the employ of the Stone and Webster Engineering Corporation, as Superintendent of Construction. He remained with this Company throughout a period of four years, during which time he was engaged on the development of bridges, dikes, street railways, power-house and sub-station construction in various parts of the United States. He later became General Manager for the Columbia Improvement Company, of Paducah, Ky., and Construction Agent and Resident Engineer for the Baton Rouge, La., Gas and Electric Light Company. He also served as Superintendent of Construction for the Jacksonville Traction Company, of Jacksonville, Fla.

In 1908, Mr. Hallett was employed by the J. G. White Company as General Manager for the L. N. Farnham Construction Company, on the Little River Water Supply of Springfield and Westfield, Mass. In 1909, he again went South and served as Assistant City Engineer, Assistant Building Commissioner, and Chief Clerk for the City of Jacksonville.

In 1918, at the expiration of ten years of service in Jacksonville, Mr. Hallett went North to accept a position with the Massachusetts State Highway Department where he remained for about three years. His subsequent positions were with the American Woolen Company, when Shawsheen Village was planned and developed, with the Boston and Maine Railroad Company, and, at the time of his death, he was Engineer in Charge of the construction of the Manger Hotel, in Boston.

He was a Mason, a member of Friendship Lodge, Taylors Falls, Minn. He was also a member of the Florida Engineering Society and of Adelbert Ames Camp No. 19, Spanish-American War Veterans, Lowell, Mass.

He had a winning personality and made many friends in the various places where he had lived, to all of whom his untimely death was a great shock.

Mr. Hallett was married on June 28, 1905, to Ethel Foster, of Tewksbury, Mass., who survives him. They had one son, James, who was born in Florida on December 9, 1907.

Mr. Hallett was elected an Associate Member of the American Society of Civil Engineers on June 23, 1916.

LEWIS STIRLING HEREFORD, Assoc. M. Am. Soc. C. E.[1]

DIED APRIL 13, 1931

Lewis Stirling Hereford was born in Baton Rouge, La., on April 15, 1875. His father was a Captain in the Confederate Army and a Louisiana sugar planter. His mother was Rowena (Percy) Hereford, also a native of Louisiana.

Mr. Hereford was educated at the Louisiana State University and his first engineering work was on the Mississippi River levees; afterward, he went to Helena, Ark., where he was engaged in municipal engineering. From there he went to Atchison, Kans., where he served as Assistant City Engineer under the late Frederick Giddings, M. Am. Soc. C. E. After several years, he was appointed County Engineer and, in that office, built many bridges and roads. In 1912, he went to Lake Charles, La., where he was engaged in road and bridge building.

In 1920, Mr. Hereford went to Charlotte, N. C., and started the first Piggly Wiggly Store, gradually increasing them in number until he had seven, when he finally sold them. They were very successful and were outstanding in their upkeep and cleanliness, thereby setting a standard that competitors had to try to meet or suffer by comparison.

After Mr. Hereford sold his stores in 1927, he did not engage actively in any business. He was Treasurer of the Carolina Cork Roll Company of Charlotte. He was also active in the affairs of the Rabbit Breeders Association, and was the pioneer in the introduction of Rex rabbits in this section of the United States. He had many fine specimens which he had imported from England and Canada. The same scrupulous care was given to his rabbits that went with everything he undertook, and his hutches were taken as models for many others that were started later.

Mr. Hereford had a host of friends who regret his passing and who sincerely realize that in him the community has lost a fine type of citizen.

In 1903, Mr. Hereford was married to Christina Giddings, the daughter of the late Mr. Giddings, who survives him.

Mr. Hereford was elected an Associate Member of the American Society of Civil Engineers on January 17, 1916.

WILLIAM CHAFFIN HOWE, Assoc. M. Am. Soc. C. E.[2]

DIED SEPTEMBER 16, 1930

William Chaffin Howe was born in Worcester, Mass., on April 19, 1876, the son of William B. and Harriet (Chaffin) Howe. His early education was received in the Worcester Public Schools, from which he entered the Worcester Polytechnic Institute with the Class of 1893.

---

[1] Memoir prepared by L. W. Cuddy, Pres., Carolina Cork Roll Company, Charlotte, N. C.

[2] Memoir prepared by Philip L. Wilder, Esq., Worcester, Mass.

Mr. Howe's first position after leaving the Institute was with the Washburn and Moen Company, in Worcester, with which he served as Designer of automatic machinery until 1894, when he went to Norcross Brothers, of Worcester and Boston, Mass., as Structural Draftsman and Checker. In 1897, he severed his connections with Norcross Brothers and entered the employ of the A. F. Hawkins Iron Works, in Springfield, Mass., as Office Assistant in charge of structural work, and he continued in the same capacity with the Mace Moulton Construction Engineering Company, when it took over the Hawkins Company.

In 1901, Mr. Howe went to the Eastern Bridge and Structural Company, at Worcester, Mass., as Checker on structural details. In 1905, he was made Contracting Engineer, in charge of the New England Territory, a position he held until shortly before he passed away.

Mr. Howe was a member of the Central Congregational Church, the Unitarian Men's Club, the Worcester Society of Civil Engineers, the Fay Club of Fitchburg, Mass., Past Master of Athelstan Lodge, A. F. and A. M., a member of the Scottish Rite Bodies, the Worcester County Commandery, and Phi Gamma Delta Fraternity.

He was married on November 4, 1898, to Ella Harned, of Philadelphia, Pa., and their son, Wilfred Harned, of Winchester, Mass., survives his parents.

Mr. Howe's unfailing cheerfulness won for him a wide circle of friends throughout New England, and to those whose privilege it was to know him intimately, his thoughtfulness, his love of doing for others, and the enjoyment it gave him, are constant sources of inspiration. William Chaffin Howe was a success in the broadest sense of the word. He is greatly missed.

Mr. Howe was elected an Associate Member of the American Society of Civil Engineers on September 2, 1914.

FRANK BURDETTE KIEL, Assoc. M. Am. Soc. C. E.[1]

DIED DECEMBER 31, 1930

Frank Burdette Kiel, was born in Lowell, Mich., on March 16, 1889, the son of Edward E. and Rose (Kinyon) Kiel. His grandfather, Simon Everett Kiel, served three years with the Third Michigan Regiment of Engineers and Mechanics during the Civil War.

Mr. Kiel attended school at Lowell and at South Bend, Ind., where he was graduated from the High School in 1907, winning special distinction in mathematics. He attended the Engineering College of the University of Michigan and after a complete four-year course in Civil Engineering received the degree of Bachelor of Science in Engineering in June, 1912.

---

[1] Memoir prepared by a Committee consisting of Henry L. Fruend, William G. Fargo, Horace S. Hunt, the late W. W. Tefft, and A. Streiff, Members, Am. Soc. C. E., Herman H. Block, Assoc. M. Am. Soc. C. E., and C. H. Wolf, Jun. Am. Soc. C. E.

Following his graduation from college, he entered the Engineering Department of the City of Flint, Mich., where, for three months, he was engaged on location for a proposed extensive sewerage system. He then entered the employ of the Grand Rapids, Holland, and Chicago Railroad Company, and was placed in charge of the surveys and mapping for extension of trackage.

His next appointment was with the Kent County, Michigan, Good Roads Commission, for which he took charge of surveys and preliminary work on a proposed highway system.

In January, 1913, Mr. Kiel entered the employ of the Fargo Engineering Company of Jackson, Mich., conducting field surveys and investigations for proposed water power and reservoir sites in Michigan, Indiana, and Wisconsin. He was in charge of the field work for reports on the physical condition of properties in the appraisal of the Pere Marquette Railroad System and of its proposed electrification. He was also in charge of field investigations for storage reservoirs and hydro-electric plants on the Red Cedar and Chippewa Rivers in Wisconsin, conducting surveys, river gaugings, railroad and highway relocations, and diamond drill test borings for five dam sites.

From November, 1915, until February, 1917, he was Principal Assistant Engineer under Joel D. Justin, M. Am. Soc. C. E., Resident Engineer, on the construction of the Wissota Plant, a 50 000-h.p. hydro-electric development on the Chippewa River, for the Wisconsin and Minnesota Light and Power Company.

Mr. Kiel was then appointed Resident Engineer on the construction of the Alcona Hydro-Electric Development on the Au Sable River, in Michigan, for the Consumers Power Company, at the same time having supervision of construction at both the Mio and Foote Developments on the same river.

In December, 1917, he was made Assistant Construction Superintendent on the Junction Dam on the Manistee River, in Michigan, in special charge of sluicing operations for the placing of embankment material. The Junction Development is a 16 500-kw. hydro-electric plant of the Consumers Power Company of Michigan.

In April, 1918, Mr. Kiel enlisted for World War Service in the United States Army, Ordnance Department, Nitrate Division, and was stationed at Sheffield, Ala., on the construction and operation of United States Nitrate Plant No. 2. He was specially assigned to the construction of a 90 000-kw. steam power plant. He was honorably discharged from service in April, 1919, but remained by special request, under civil service, as Civil Engineer n the Ordnance Department at Large, in charge of various tests and reports on the manufacture of ammonium nitrate. In June, 1919, at the completion of this assignment, he was granted an indefinite leave of absence. For his war service he was commended by his commanding officer, Lt. Col. J. K. Clement, Ordnance Dept., U. S. A., and recommended for a commission.

On leaving the Government Service Mr. Kiel organized the firm of Bird and Kiel, Consulting Engineers, engaged in general engineering practice at Little Rock, Ark., making investigations and reports on hydro-electric developments, design and construction of highways and bridges, and investigations for drainage projects, levees, and revetments.

He returned to Michigan in July, 1920, and again entered the employ of the Fargo Engineering Company. He was placed in charge of construction for the Elm Street Steam Plant, at Battle Creek, Mich., for the Consumers Power Company of Michigan. After this assignment, during 1921 and 1922, he was Resident Architect, in charge of the construction of the First Methodist Episcopal Church of Jackson, a $350 000 edifice.

In July, 1922, Mr. Kiel returned to Wisconsin as Resident Engineer, for the Fargo Engineering Company, on a 20 000-h.p., hydro-electric development at Jim Falls, on the Chippewa River, for the Chippewa Power Company. On the completion of this project, he was engaged in field investigations and compilations of reports for proposed power-plant developments in North Carolina and Michigan. In June, 1924, work was resumed on the Alcona Development, on the Au Sable River of Michigan, and Mr. Kiel was again placed in charge of construction, with special supervision of difficult deep quicksand foundations. In the fall of 1924, he made surveys of the grounds and layout for a $1 250 000 High School Building, in Jackson.

In November, 1924, Mr. Kiel entered the organization of the Commonwealth Power Corporation, of Jackson, for which he worked upon special investigations and reports for various power plants and water supply systems. During this assignment, he was engaged on the design and supervision of construction of the Hales Bar Steam Plant for the Tennessee Electric Power Company, of Chattanooga, Tenn., on the Saginaw River Steam Plant, and on the Wealthy Street, Grand Rapids, Steam Plant for the Consumers Power Company of Michigan. He was then transferred to the Commonwealth Power Corporation and was engaged on the completion of the Wealthy Street Steam Plant. He also collaborated on an extensive power survey and reports for the Republic Iron and Steel Company, at Youngstown, Ohio, making estimates of cost and preliminary layouts for a project involving the proposed expenditure of $15 000 000. He was then engaged on several proposed steam power projects, with special attention to condenser cooling water problems and hydraulic requirements.

On the organization of the Allied Engineers, Incorporated, as successors to Stevens and Wood, Mr. Kiel was assigned to special problems in connection with a large coal dock at Saginaw, Mich., for the Saginaw River Steam Generating Plant, a 140 000-kw. installation for the Consumers Power Company, and also on extensions to the Saginaw Heating Plant.

In May, 1930, he rejoined the organization of the Fargo Engineering Company and was engaged on specifications and preliminary plans for a series of hydro-electric developments.

Mr. Kiel passed away on December 31, 1930, after a short illness. At the time of his death, he was working on construction problems in connection with a 20 000-kw. hydro-electric development, storage reservoir, and long multiple-arch dam across the Colorado River, in Texas, for the Central

Texas Hydro-Electric Company, to which he had been assigned as Division Engineer with headquarters at Austin, Tex.

He belonged to the American Legion. He was a Mason, affiliated with Jackson Lodge No. 17, and an active member in the Masonic Country Club. He was a member of the Official Board of the First Methodist Episcopal Church of Jackson, and took a deep interest in the religious life of the community. He was an active member of the Civic Music Association. He was a life member of the Michigan Union, a registered Civil Engineer in the State of Michigan, and a Past-President and one of the founders of the Jackson Engineers Club. The engineers of Jackson feel that by the death of Frank Kiel, they and the profession in general have lost a true friend and valued associate. Resolutions and a testimonial to this effect were passed by the Engineers Club.

In December, 1924, Mr. Kiel was married to Helen Peters, of Battle Creek, Mich. He is survived by his widow and a son, Donald Franklin Kiel.

Mr. Kiel's character and personality are best described in the funeral tribute paid him by his friend, pastor, and associate, the Rev. Frederick Spence, D.D., as follows:

> "Everybody liked Frank. He had a rare personality. He made friends and held them. He was honest, kind to the point of personal sacrifice, giving himself to others in a way that is very rare among men in this highly individualistic age. He radiated friendliness and good will, and those who knew him trusted and loved him. Efficient in his chosen field, he yet found time to be interested in everything that was for the good of Society."

Mr. Kiel was elected an Associate Member of the American Society of Civil Engineers on November 25, 1919.

JOHN BRUCE MAILEY, Assoc. M. Am. Soc. C. E.[1]

DIED APRIL 29, 1932

John Bruce Mailey was born in Lynn, Mass., on August 22, 1886, the son of John Augustus and Rebecca (Twisden) Mailey, who were also born in Lynn.

Mr. Mailey's early life was spent in Lynn, where he received his preliminary education. He continued his studies at Tufts College, Medford, Mass., from which he was graduated with the degree of Bachelor of Science in Structural Engineering in 1910. In 1911-12, he took a course in Bridge Design at the Harvard Graduate School of Applied Science.

From 1910, following his graduation from Tufts, until his death in 1932, Mr. Mailey specialized in structural engineering. His successive engagements and positions were, briefly, as follows: From 1910 to 1912, various positions which involved structural detail drafting and design; and from 1912 to 1917, with the Boston and Maine Railroad Company as Structural Designer and Squad Boss in the Bridge Department and Assistant Engineer in the Valuations Department. During the World War (1917-18) he served in the Air Service.

---

[1] Memoir prepared by Dana N. Peaslee, Esq., Boston, Mass.

From 1919 to 1921 he was connected with the Bridge Department of the Boston and Maine Railroad Company; from 1921 to 1923 with the United States Railroad Administration, as Bridge and Building Engineer; and from 1923 to 1924 with Charles T. Main Company, Boston, Mass. From 1924 until the time of his death, Mr. Mailey was connected with Stone and Webster Engineering Corporation. In the capacities of Structural Designer and Engineer, he assisted in the design and construction of central power stations and industrial plant developments.

He manifested loyalty to his employers and devotion to his work. Untiring in his efforts to accomplish results, he did not shrink from devoting long hours to his duties. He was a cheerful and likable person, making true friendships with a large number of men to whom he was devoted and loyal.

Mr. Mailey was interested in the Masonic Bodies, and was a Thirty-second Degree Mason.

He was not married, but his disposition reflected the happy home life which he shared with unusual filial devotion with his aged mother. He died rather suddenly of spinal trouble, in Andover, Mass., on April 29, 1932, and is buried in Pine Grove Cemetery, in Lynn.

Mr. Mailey was elected a Junior of the American Society of Civil Engineers on April 30, 1912, and an Associate Member on May 15, 1917.

ALFRED STOWE MIRICK, Assoc. M. Am. Soc. C. E.[1]

Died December 6, 1931

Alfred Stowe Mirick, son of Ira and Sarah K. (Croul) Mirick, was born at Lyons, N. Y., on February 16, 1877. His maternal grandfather was Columbus Croul, a pioneer settler of Lyons. Mr. Mirick attended the Lyons Union School, from which he was graduated in 1896. He then entered Cornell University, and received his degree in Civil Engineering in 1901.

Upon graduation, he went with the Chicago and Northwestern Railroad Company as Rodman and Instrumentman. In July, 1902, he became Draftsman for the American Bridge Company, at Canton, Ohio, and Pittsburgh, Pa. In November of that year, he joined the Columbia Bridge Company, at Carnegie, Pa., as Squad Master in charge of details. In the autumn of 1903, he took a position with the Altman Company, of Canton, in charge of the structural work of the Elevating and Conveying Department. When this Department was sold to the Interstate Engineering Company, of Bedford, Ohio, in 1904, Mr. Mirick became Chief Draftsman of the Interstate Engineering Company, organizing and overseeing the drafting-room, laying out and designing new work, and submitting preliminary sketches and specifications.

---

[1] Memoir prepared by William W. C. Perkins, M. Am. Soc. C. E.

In March, 1908, Mr. Mirick went with the New York State Engineer and Surveyor as Assistant Engineer, first in charge of highway improvements and, in December, on the Barge Canal, in the Bureau of Locks, designing concrete structures. Later, he went to Albany, N. Y., with the State Highway Department, where he remained as Resident Engineer until 1917. Mr. Mirick was then appointed Chief Road Engineer and Chief of Construction of the Nebraska State Highway Department at Lincoln, Nebr., where he remained until 1923, when he became District Engineer for the Eastern Paving Brick Manufacturers Association, at Pittsburgh, Pa. He continued with the Association until August 1, 1930, with the exception of one year when he was General Sales Manager for the Clydesdale Brick and Stone Company, at Pittsburgh.

In August, 1930, he went to California and remained there until August, 1931, when he accepted a position with the Nebraska State Highway Department as Project Engineer, with headquarters at Lincoln, which position he held at the time of his death.

Mr. Mirick died on December 6, 1931, after suffering a stroke of apoplexy n his room at the Young Men's Christian Association Building, at Lincoln. He was buried in the Rural Cemetery at Lyons, N. Y., where a number of his ancestors lie. His funeral was conducted by Lodge No. 19, F. and A. M., of Lyons, to which he belonged.

Mr. Mirick leaves a widow and two daughters, Mrs. Jeanette (Mirick) Button and Florence Mirick, all of Hollywood, Calif. Other survivors are an aunt, Anastasia Mirick, a brother, Nelson C. Mirick, both of Lyons, and a half-brother, Clarence Beckwith, of Rochester, N. Y.

He was of a quiet and retiring disposition, and a man who made and kept a great many friends. He was a high type of Engineer and especially good n promotion work.

A friend and business associate of Mr. Mirick, at Lincoln, writes:

"I knew him well from 1919 to 1923 and wrote to him occasionally until ast summer when he returned to Lincoln to work. It was common comment around the office about Mr. Mirick's courtesy and gentlemanly behavior. He was a good engineer and worked well with us. The men in the office held him in very high esteem."

Mr. Mirick was elected an Associate Member of the American Society of Civil Engineers on October 5, 1909.

JOSEPH LINCOLN MURPHY, Assoc. M. Am. Soc. C. E.[1]

DIED FEBRUARY 20, 1932

Joseph Lincoln Murphy, the son of Joseph D. and Isabelle (Evans) Murphy, was born at Creola, Ohio, on January 29, 1877.

His preliminary education was obtained in the schools of Vinton County, Ohio. All his boyhood was spent there with the exception of one year in Nebraska when his family moved to that State to take up a homestead claim.

---

[1] Memoir prepared by G. F. Schlesinger, M. Am. Soc. C. E.

The most vivid memories of his boyhood were the trip to Nebraska in a covered wagon, the sod house his father built, and the hardships endured before it was finally decided to return to their old home in Vinton County.

Circumstances would not permit the boy's regular attendance at school, but possessed of tireless ambition, the early age of fifteen found him working in a saw-mill, performing the tasks of a grown man, so that he might have enough money to go to school.

On entering the High School at McArthur, Ohio, Mr. Murphy lived in the home of Dr. Rannells, and his time outside school hours was employed in driving the doctor through the country on his round of calls. Here, he came to know Miss Eliza Rannells, a teacher, who took a great interest in him, encouraged him in his efforts to continue with his education, and it was through her direction and influence that he acquired his taste for fine literature. Reading was always the source of his greatest enjoyment, and his ready fund of knowledge on a multitude of subjects made him an interesting conversationalist.

Extremely interested in military affairs, on May 11, 1897, at the age of twenty, and while still a student in High School, he enlisted in the Ohio National Guard, becoming a member of the Hospital Corps of the 17th Ohio Infantry.

On April 26, 1898, Mr. Murphy enrolled in Company B, 17th Regiment of Infantry, Ohio Volunteers, to serve two years, or for the duration of the Spanish-American War. He served seven months, receiving his discharge on November 6, 1898; during this period his Company was encamped at Columbus, Ohio, and at Washington, D. C. His services in the Army left his health in such condition that he could honorably have asked for a pension, but, characteristically, refused to do so.

During the World War, he twice attempted to enter the service of the Government, but each time, greatly to his disappointment, was unsuccessful, owing to defective eyesight caused from an injury sustained when a boy.

Upon receiving his discharge from the Army, in 1898, Mr. Murphy returned to McArthur, Ohio, and determining at all costs to continue his education, re-entered High School, graduating in April, 1899, at the age of twenty-two.

He was anxious to take up the study of Law, and encouraged and aided by Dr. Rannells and Miss Rannells, entered Ohio State University, at Columbus, Ohio, in the fall of 1899. Unable to qualify for the Law School because of a lack of proper credits, he enrolled in the Civil Engineering School. Four years of unceasing work and study, with little or no recreation followed, and, in 1903, he received his degree in Civil Engineering.

In 1905, Mr. Murphy moved to the Hocking Valley, in the southeastern part of the State, where the remainder of his life, with the exception of the two years preceding his death, when he resided at Columbus, Ohio, was spent.

During his last year in college, Mr. Murphy met Mr. E. M. Poston, President of the New York Coal Company, who was prominent in the coal and power industries in Ohio, and particularly in the Hocking Valley, where most of his large holdings were located. Following his graduation, Mr. Murphy was employed by Mr. Poston as Engineer for his many enterprises.

Assuming the position of Chief Engineer, he organized and built up the Engineering Department of the New York Coal Company, and, in the ensuing years, his opinion on tax and mine engineering problems was widely sought and highly valued.

Possessed of rare judgment in the selection of his men, Mr. Poston readily perceived that here was a man in whom he could place unbounded confidence and responsibility, and the story of Mr. Murphy's career is the story of the coal, clay, oil, and power developments of Mr. Poston in the last twenty-eight years—a story written deeply in the annals of the Hocking Valley. In the years of his association with the New York Coal Company, Mr. Murphy was actively engaged in all the various branches of the organization, and was an Officer and Director in many of its associated companies.

When the Manhattan Oil Company, a subsidiary of the New York Coal Company, was organized, Mr. Murphy was made its managing head, and, for many years, was a familiar figure in the oil and gas developments of the New Straitsville, Ohio, Lima, Ohio, and Hocking Valley fields.

In 1912, the paving-brick plant of the Hocking Valley Brick Company, at Logan, Ohio, was added to the already large holdings of the New York Coal Company, Mr. Murphy becoming President of the new Company. Thus, began the work to which the remaining years of his life were dedicated. From that time on, his activities were principally directed in the Brick and Tile Department of the organization. Subsequently, the plants of The Nelsonville Brick Company and The Ohio Fire Proofing Company at Nelsonville, Ohio, and The Zanesville Clay Products Company, at Zanesville, Ohio, were acquired, with Mr. Murphy holding the position of Chief Executive. It was chiefly through his association with these Companies that he was so widely known, and, in the course of years, became a recognized leader in the clay industry throughout the State.

He was intensely interested in the civic welfare of the Hocking Valley and it was to a great extent due to his efforts that a Young Men's Christian Association Building was erected at Nelsonville. He also designed and helped in the construction of the Protestant Episcopal Church, at Nelsonville, and contributed greatly toward its maintenance. He gave to any cause for the advancement of public welfare a full measure of time and devotion. Increased recognition for the Hocking Valley in the industrial affairs of the State was his greatest desire, and the goal toward which he worked. In his going, the Hocking Valley District of Ohio lost one of the most devoted of her adopted sons.

His keen Irish wit, unlimited capacity for friendship, and unquestioned ability, made him a dominant figure in any group. Mr. Murphy was a leader in a number of clay products associations, having served the Ohio Paving Brick Manufacturers Association as President for thirteen years, and at the time of his death, he was Chairman of the Executive Committee. A resolution passed by this Association, states in part:

"* * * a fair fighter and an honest competitor. He won every advancement entirely through his own efforts. His was a dynamic force that knew no such word as 'fail'".

For a number of years he served on the Board of Directors of the National Paving Brick Association, and at all times was actively engaged in its affairs. He was also Treasurer of the Structural Clay Tile Association for a number of years, subsequently serving as a Director and a member of the Executive Committee.

Recognizing the need for scientific research in the ceramic industry and realizing that few, if any, of the ceramic corporations of Ohio were large enough to support this much needed research in their own organization, Mr. Murphy, with several other forward-looking, prominent ceramic men, set about to devise means whereby a ceramic research bureau might be established to serve all branches of the industry in Ohio. It soon became evident that some organization, or group of ceramic manufacturers, would have to stand sponsor for the research. Accordingly, these men, inspired largely by the enthusiasm of Mr. Murphy, set about to organize what has since become the Ohio Ceramic Industries Association, now comprising nearly one hundred and twenty corporations, and fully three-quarters of the production capacity of the State.

Under the direction of this organization, when Mr. Murphy was President, the Ohio State University was persuaded to make ceramic research a major project in its Engineering Experiment Station. Contracts were entered into between the Ohio State University and the State Welfare Department which made possible the establishment of an experimental research station in connection with the State Brick Plant, at Roseville, Ohio. Thus, Mr. Murphy's dream became a reality. This Station has developed until it is now the most outstanding ceramic research organization in the United States and in the world. During the years since the formation of this Association, Mr. Murphy was continually one of its active and enthusiastic members. In recent years, he served as Chairman of the Public Relations Committee, in which capacity he was notably successful in representing the ceramic industry of Ohio, and presenting its cause and viewpoint to the State Legislature and to other individuals, boards, and bureaus associated with the State Government. The part he played in the organization of the Ohio Ceramic Industries Association ranks as one of the major achievements of his life. The active head of this Association states:

> "The entire ceramic industry of Ohio owes a debt of gratitude to J. L. Murphy who gave so unstintingly of his time and efforts and accomplished so much for the industry as a whole."

Early in 1931 Mr. Murphy, through his activities in the American Ceramic Society, was named Chairman of the Executive Committee in charge of the ceramic "Century of Progress" exhibit at the Chicago World's Fair Exposition to be held in 1933.

In the fall of 1931, death claimed Mr. Poston, and Mr. Murphy, with countless others, was deeply grieved at the loss of friend and employer. Under Mr. Poston's will, Mr. Murphy became one of the Trustees of the Poston

Estate, an added honor and responsibility which he keenly felt. From the time of Mr. Poston's death until his own, Mr. Murphy was noticeably changed. Always, he had welcomed with eager enthusiasm every problem of his work-crowded life, and was alert and active until the very end. He died suddenly from a heart attack on February 20, 1932, after returning home from a short walk with his dog.

He was a staunch Republican, and consistently took a keen and active interest in politics. He was a member of the Masonic Lodge, including the Scottish Rite and the Shrine; a member of the Benevolent and Protective Order of Elks; and, because of his interest in the Mooseheart School for children, held a life membership in the Order of Moose. He was a member of Kiwanis, the Engineers Club of Columbus, The Ohio Engineering Society, Columbus Athletic Club, and the Ohio Society of New York, N. Y.

Mr. Murphy was individualistic by nature; yet an editorial appearing in a Columbus newspaper following his death, said in part:

> "Among those prominent in the development of the Hocking Valley, few, if any, were better known or better liked than 'Pat' Murphy. He had a rare faculty for making and keeping friends, and he had the gift of retaining the respect even of those who disagreed with him."

Deeply interwoven in the threads of his life was his love for children. It was chiefly through his concern for the welfare of their families that his employees came to know him more as friend than employer.

Because his own early struggles were ever fresh in his mind, many young men and women acknowledge their debt of gratitude to him for the educational advantages he so willingly offered, asking only that they, in turn, whenever possible, help another deserving student.

Generous to a fault, giving freely of himself and his means to those who called on him, "he saw keenly enough where he was imposed upon, and yet for fear of dropping below the abnormally high standard of generosity and honor he held himself to, went on doing for the impostors. This was the combination of characteristics which made him what he was."

In one of the last books Mr. Murphy read, this passage was found marked: "* * * note that a little height made a sight of difference the way a body saw things," and those nearest this gracious, kindly man knew that he reached heights from which harsh judgment was rarely pronounced; that he had touched greatness. Easily approached, his fellow-workers came to him with their sorrows, nor were turned away unheeded; in their hearts his memory will long endure; for them a light has gone out.

On June 14, 1905, he was married to Margaret Duvall, of Columbus, Ohio, who, with two brothers, Daniel Murphy of Columbus, and Hulbert Murphy, of Chicago, Ill., and two sisters, Mrs. A. V. Allen and Mrs. Homer Timms, of Columbus, survives him.

Mr. Murphy was elected an Associate Member of the American Society of Civil Engineers on May 6, 1914. He was also a Member of the Central Ohio Section of the Society.

ROBERT McKNIGHT PARDEE, Assoc. M. Am. Soc. C. E.[1]

Died April 10, 1930

Robert McKnight Pardee was born in Fort Wayne, Ind., on March 27, 1885, the son of the late William McKnight Pardee, Division Engineer of the New York, Chicago, and St. Louis Railroad Company (The Nickel Plate).

Mr. Pardee received his early education in Fort Wayne and New Harmony, Ind. He entered New York University in the fall of 1902, and was graduated with the degree of Bachelor of Science in Civil Engineering from the School of Applied Science, with the Class of 1906. During his Junior and Senior years at the University, he was Business Manager of *The Triangle,* a weekly publication of the students.

After his graduation, from August, 1906, to October, 1911, Mr. Pardee was a member of the Engineering Department of the Grand Trunk and Pacific Railway Company in Western Canada, and worked on every part of the route from Winnipeg, Man., to Prince Rupert, B. C., on preliminary location and construction. Beginning as Tapeman and Rodman, he rose to the grade of Instrumentman, then Assistant to the Resident Engineer, in which position he handled numerous difficult pieces of high side-hill and canyon work in the mountains of British Columbia, involving tunneling and heavy embankment cribbing. During the period of his employment with the Grand Trunk and Pacific Railway Company, there was, in 1907, a suspension of railroad construction for the winter due to depressed business conditions. During this time he acted as a Reporter for *The Telegram,* a Winnipeg newspaper, covering night work. In 1912, he was in the employ of Isaac S. Rossell, General Contractor, of New York, N. Y., and, later, with the Turner Construction Company, on various buildings in and around Buffalo, N. Y., including the Bell Telephone Company Building. He rose in the building field to the position of Assistant Superintendent of Construction for the Turner Construction Company.

From the latter part of 1913, until July, 1915, Mr. Pardee was a partner in the firm of Pardee and Backus, Builders, of Edmonton, Alberta, Canada, during which time numerous buildings were constructed. When the World War put a stop to the building boom in that section of Alberta, Mr. Pardee went East and again found employment with the Turner Construction Company, from July, 1915, to September, 1921. During this time he served in various capacities on construction work, in the office, as Assistant Superintendent, and as Purchasing Agent on numerous reinforced concrete buildings in the cities of the South.

In October, 1921, he left the Turner Construction Company, and established the firm of Robert McKnight Pardee, in Atlanta, Ga., representing a number of manufacturers in the sale of their building materials and specialties throughout the Southeast.

---

[1] Memoir prepared by Robert S. Fiske, M. Am. Soc. C. E.

Mr. Pardee built a home in Atlanta, and made a large circle of friends in that city. He was active in the Georgia Section of the Society for a number of years, and was a respected and honored citizen. He possessed a very pleasing personality and a genial disposition, which won for him many close friends, and he was ever ready to assist a fellow-man in any way and give aid to any worthy cause. He was punctilious in his habitis, and painstaking in the performance of his duties.

He was married in 1912, and is survived by his widow, Mrs. Emily Purvis Pardee, and four children—Jack, Constance, William, and Robert, Jr.—all of whom reside in Atlanta.

Mr. Pardee was elected an Associate Member of the American Society of Civil Engineers on May 19, 1924.

WILLIAM COUTS RANDOLPH, Jr., Assoc. M. Am. Soc. C. E.[1]

Died January 17, 1931

William Couts Randolph, Jr., was born in Atmore, Ala., on June 5, 1897, the son of William Couts, and Allie (Hill) Randolph. Soon after his birth the family moved to Russellville, Ky., about two years later moving to Springfield, Tenn., where they resided until William was four years of age. In 1901, the family made their home in Andalusia, Ala., where his youth and boyhood were spent.

Mr. Randolph attended the public schools of Andalusia and, following his graduation from the High School in 1915, he entered the University of Alabama at Tuscaloosa, Ala., where he remained for two years. While at college, he was very prominent in campus activities and was a member of Pi Kappa Phi Fraternity.

From June, 1917, to October, 1918, he was employed by J. B. McCrary Company, of Atlanta, Ga., as Rodman, Instrumentman, and Tracer in connection with the construction of Southern Field at Americus, Ga. Following this engagement, he spent about four months in the employ of the United States Corps of Engineers at Charleston, S. C., as Piling Engineer in connection with dock construction at that place.

From January until June, 1919, Mr. Randolph was employed by the Lockwood-Greene Company as Chief of Topographic Party in connection with maps and surveys at Fort Benning, Georgia; and from June, 1919, until February, 1920, he was Resident Engineer on general highway work in the southern part of Georgia.

Beginning in February, 1920, he served for ten years with the State Highway Department of Georgia, where his progress was rapid and where he built for himself a remarkable reputation in the construction of paved highways. For two years he was Division Draftsman and, for another two-year period, he was Resident Engineer in charge of the construction of highways in the Americus Division of the Department. From July, 1924, until May, 1928, he was Senior Engineer in technical charge of all highway construction in nineteen counties for the State Highway Department. His ability was fully recognized by this time, and he was designated as Supervising Engineer and placed in charge of the paving on the Atlanta-Chattanooga Road. This work included the paving of about ninety-two miles of road and involved five different contracts.

---

[1] Memoir prepared by a Committee of the Georgia Section consisting of Thomas M. Neibling, Assoc. M. Am. Soc. C. E., *Chairman,* and W. R. Neel, and S. B. Slack, Members, Am. Soc. C. E.

In January, 1930, Mr. Randolph left the Georgia Highway Department to become associated with The Dixie Culvert and Metal Company in charge of engineering, research, and development in the Southeast. He carried on this work enthusiastically until he was seized with an acute attack of appendicitis which caused his death in Atlanta, on January 17, 1931.

Although a comparatively young man, Mr. Randolph was an ardent and enthusiastic Engineer, and at all times exemplified and advocated the high standards of honor, diligent work, and efficiency for which his profession stands. In every community in which he lived he was regarded as a useful and highly respected citizen, and he was held in high esteem by his professional associates everywhere. His fine character, enthusiasm, and interesting personality made for him a wide circle of friends.

On June 1, 1918, he was married, at Americus, to Genevieve Prather, who survives him, with two daughters, Ruth and Elizabeth, and one son, James.

Mr. Randolph was elected an Associate Member of the American Society of Civil Engineers on June 9, 1930.

HOMER AUSTIN REID, Assoc. M. Am. Soc. C. E.[1]

Died June 9, 1931

Homer Austin Reid, the son of Elias H. and Maria U. (Ulrich) Reid, was born in Bristol, Ohio, on September 30, 1869. He attended the public schools in Warren, Ohio, and secured his engineering education at Lehigh University, Bethlehem, Pa., which he attended from September, 1891, until his graduation in June, 1896, with the exception of one school year (1893–1894), when he managed the business of the firm of E. H. Reid and Son, lumber dealers, in Warren. During other summer vacations, he worked on survey parties for the City Engineer of Warren.

After his graduation, Mr. Reid's first employment was from June, 1896, to April, 1897, with the Norfolk and Western Railroad Company, Lynchburg Division, in charge of maintenance-of-way work. Later, until August, 1897, he worked for the Warren Gas Light Company, compiling a map of the City of Warren. From August, 1897, to August, 1899, he was employed as Draftsman on structural steel detailing by the Youngstown Bridge Company, of Youngstown, Ohio, and by the Penn Bridge Company, of Beaver Falls, Pa. This work had a particular appeal to Mr. Reid and led him to specialize in the structural engineering branch of the profession. His subsequent engagements for the Greenbrier Railway Company (a branch of the Chesapeake and Ohio System), for the State Engineer and Surveyor, at Albany, N. Y., and for Milliken Brothers, in New York, N. Y., were on bridge and structural design.

---

[1] Memoir prepared by John W. Cunningham, M. Am. Soc. C. E.

In March, 1901, Mr. Reid entered the employ of the New York Rapid Transit Commission. Starting as Inspector, he rose to the position of Division Engineer. On the completion of his Section, he became Chief Engineer of the Bureau of Buildings, Borough of Manhattan. Using this wide acquaintance and experience with municipal work, in 1900, Mr. Reid opened a consulting office in his own name. He was immediately successful and handled a number of large buildings. One feature of his work was the design of the framework for many of the large electrical signs on Broadway.

During the period of the World War, Mr. Reid was Engineer and Manager for the Foundation Company in New York and Canada. Afterward, in 1919, he was Resident Engineer on the repair of the Grand Trunk Bridge, at Niagara Falls, N. Y., and Ont., Canada. From 1919 to 1922, he was Office Engineer for Lockwood Greene and Company, Architects and Engineers, in the New York Office, Field Engineer for Hardy S. Ferguson, M. Am. Soc. C. E., and in charge of extensive port improvements at Puerto Tarafa, Cuba, the largest sugar port in the world. For the following years, until 1927, he was with the organization of Albert Kahn, Architects, in Detroit, Mich., as Assistant Chief Engineer, having to do principally with large industrial buildings.

In 1927, in order to secure a climate more favorable to his wife's health, Mr. Reid moved to Los Angeles, Calif. He handled several structural jobs in that city and in Long Beach, Calif. In the fall of 1930 he went to Portland, Ore., where he intended to locate as a Consulting Engineer. His plans were interrupted, however, by his sudden death on June 9, 1931.

Mr. Reid was by nature quiet and was devoted to his studies along professional lines. In 1907, when the theory and practice of concrete design was being most rapidly developed, he wrote an extended treatise entitled "Concrete and Reinforced Concrete Construction," which met an immediate acceptance by the profession. The preface of this work contains a plea for engineering judgment and conservatism that deserves quotation:

> "Although the increase in the use of concrete, both with and without reinforcing metal, has become so great in the past few years as to almost warrant it being said that we are going concrete mad, it should be remembered that reinforced concrete does not possess wonderful and mysterious properties such that it may be unscientifically or recklessly used. To the contrary, it should be used with the same care and judgment that has made other and older kinds of construction both safe and satisfactory. It should also be remembered that there are other and tried kinds of construction, which are much more suitable for use in many situations. Under such conditions enthusiasm for a given form of construction should be tempered with good judgment, and the most suitable building material chosen * * *."

Mr. Reid was a Mason, affiliated with the Youngstown, Ohio, Lodge, and a member of the Protestant Episcopal Church.

He is survived by his widow, Ednor (Smith) Reid, and a daughter, Mrs. John O. Davis, of Portland; also, a brother, Halbert Reid, of Liberal, Kans., and a sister, Mabel Reid, of Warren.

Mr. Reid was elected an Associate Member of the American Society of Civil Engineers on December 4, 1901.

HERBERT JONES SOWDEN, Assoc. M. Am. Soc. C. E.[1]

DIED NOVEMBER 14, 1931

Herbert Jones Sowden, the son of George and Anna Sowden, was born in Philadelphia, Pa., on November 8, 1883. He was educated in the public schools of Philadelphia, and was graduated from the Northeast High School in 1901. His technical training was received through attendance in the evening classes at Franklin Institute from 1901 to 1903.

Mr. Sowden was ambitious to become a Civil Engineer and, after his graduation from High School in 1901, he entered the employ of the Philadelphia and Reading Railway Company as a Chainman, and remained in its service until January, 1914. While with this Company he received several promotions, and eventually attained the grade of Assistant Engineer of Construction, which position he held until the termination of this connection. During this period he was engaged on the elimination of grade crossings on the 9th Street Section of the Philadelphia, Germantown, and Norristown Railroad, and on the Port Richmond Branches of the Philadelphia and Reading Railway, in Philadelphia. He was also employed in the laying out of the New York Short Line Division of this Railway Company. In 1914, he assumed charge of the building of the Wayne Junction Station, on the main line of the Philadelphia and Reading Railway, as Superintendent of Construction for the Contractor, Charles P. Bower, M. Am. Soc. C. E.

Upon the completion of this assignment, in 1915, Mr. Sowden accepted an appointment with the City of Philadelphia, as Sewer Inspector in the Bureau of Surveys, Department of Public Works. He held this position until 1923, when he was promoted to the rank of Assistant Engineer in the Division of Grade Crossing Elimination, Bureau of Surveys, Department of Public Works, and was assigned to the South Philadelphia Terminal Improvements. This work included the abolishment of numerous grade crossings upon the lines of The Pennsylvania Railroad, The Baltimore and Ohio Railroad, and The Schuylkill River East Side Railroad Companies, in the southern section of the city, together with several extensive viaduct approaches and the construction of railroad terminal and river-front improvements.

---

[1] Memoir prepared by Thomas Buckley, M. Am. Soc. C. E.

He was promoted in 1924 to the position of Assistant Engineer of Sewer Construction, Bureau of Engineering and Surveys, Department of Public Works, and was placed in responsible charge of all sewer construction work in the City of Philadelphia, which position he occupied until his death. As Assistant Engineer of Sewer Construction Mr. Sowden had direct charge and supervision of the present amplified sewerage system of the City of Philadelphia, during a period wherein were built many miles of branch and main sewers and appurtenant work.

Mr. Sowden was a member of Mitchell Lodge, No. 296, F. and A. M., of Pennsylvania, and the Germantown Royal Arch Chapter. He was also a member of the American Society of Municipal Engineers.

He is survived by his widow, Alice (Hobson) Sowden, a daughter, Gloria Sowden, and two sons, Herbert J. Sowden, Jr., and Richard Sowden, all of Philadelphia.

Mr. Sowden was elected an Associate Member of the American Society of Civil Engineers on October 10, 1927.

PAUL BERTRAM SPENCER, Assoc. M. Am. Soc. C. E.[1]

Died March 26, 1932

Paul Bertram Spencer was born in Boston, Mass., on October 6, 1881, the son of Lafayette and Mary (Batchelder) Spencer. He spent his boyhood on a farm at Tatnic Hill, Brooklyn, Conn., attending the Brooklyn Center School, where he prepared for college.

Mr. Spencer received his technical and engineering training at the Worcester Polytechnic Institute, Worcester, Mass., from which he was graduated in 1902, with the degree of Bachelor of Science in Civil Engineering, receiving one of the six "Graduate Aid Fund" prizes for scholarship. In 1914, his Alma Mater granted him his Civil Engineer degree.

In June, 1902, Mr. Spencer began his professional career in the Engineering Department of the New York, Ontario, and Western Railway Company, where he progressed from the position of Draftsman through the grade of Inspector to that of Assistant Engineer in November, 1902, which position he held until November, 1905.

From November, 1905, until September, 1906, Mr. Spencer served as Junior Assistant Engineer with the New York, New Haven and Hartford Railroad Company, and was engaged on the six-tracking of the Harlem River and Portchester Railroad (Harlem River Branch), between the Harlem River and New Rochelle, N. Y., particularly the river crossings at Bronx River and Pelham Bay, and grading for the Oak Point Classification and Float-Bridge Yards, in New York, N. Y.

From September, 1906, until May, 1907, he was Resident Engineer with the Charlotte Harbor and Northern Railway Company (now part of the Seaboard Air Line Railway Company) engaged on the construction of the new line from Hull to Boco Grande, Fla., which included two long trestle bridges, one involving a drawbridge span over Gasparilla Bay.

---

[1] Memoir prepared by A. C. E. Mullen, Constr. Engr., N. Y., N. H. & H. R. R., New York, N. Y.

From June, 1907, until January, 1908, as Instrumentman with the Cambria Steel Company, at Johnstown, Pa., Mr. Spencer was employed on the construction of new buildings and the erection of mine-shaft machinery.

In January, 1908, Mr. Spencer returned to the New York, New Haven and Hartford Railroad Company as Second Assistant Engineer of Construction at New York City and was again assigned to the six-tracking of the Harlem River Branch.

From June until November, 1912, he was Assistant Engineer in charge of the completion of the Harlem River Branch project, the Oak Point Yard and Float-Bridge, Van Nest and Westchester Yard improvements, and the construction of the electric repair shop at Van Nest, New York City.

From November, 1912, until March, 1916, as Division Engineer of Construction at New Haven, Conn., Mr. Spencer was in general charge of all construction work west of New London and Willimantic, Conn., the consolidation of the East River Piers and the Woodlawn Junction improvements in New York City, the double-tracking of the line, and the elimination of grade crossings between Berkshire Junction and New Milford, Conn., constituting the major projects. During this period Mr. Spencer made the studies for the location of the new Thames River Bridge, at New London, Conn.

From March, 1916, until March, 1920, Mr. Spencer, with headquarters at New London, devoted practically all his attention to work in that vicinity. This work consisted of the construction of the railroad bridge (a four-track substructure, with two-track superstructure) spanning the Thames River; the deep foundations of the river piers presented an interesting problem. This work involved the re-alignment of the railroad at Winthrop Cove on the westerly approach, and the four-tracking of the road from Groton to Midway, Conn., on the easterly approach, the enlargement of the Midway Yard, and the improvement of the engine facilities.

In March, 1920, Mr. Spencer was appointed Assistant to the late W. H. Moore, M. Am. Soc. C. E., then Engineer of Structures at New Haven, and, at Mr. Moore's death, succeeded him on October 1, 1920, as Engineer of Structures, which position he held until his sudden death on March 26, 1932.

Although no new projects of major engineering importance were carried out by the Company during this period, many varied and difficult reconstruction and maintenance problems were presented to Mr. Spencer. These he solved in a manner which indicated that his professional ability in design had been enriched by a thorough and intimate knowledge of general construction methods and railroad operating problems.

Mr. Spencer was a member of the Connecticut Society of Civil Engineers; American Railway Engineering Association, of which he was a member of Committee No. 15, "Iron and Steel Structures"; American Railway Bridge and Building Association; a member of the Presidents' Conference Committee on the Federal Valuation of Railroads; and, since 1928, a highly valued member of the "Contact Committee" for the Department of Civil

Engineering of the Worcester Polytechnic Institute. He was also a member of the New Haven Railroad Club, and Annawon Lodge No. 15, A. F. and A. M., of West Haven, Conn.

On September 21, 1904, Mr. Spencer was married to Anna A. Basler, of Newark, N. J., who, with an only daughter, Doris Marie Spencer, survives him.

To the end, an earnest student, an indefatigable worker, Mr. Spencer possessed, to a marked degree, those fundamental attributes of the successful engineer—perseverance and a logical creative mind. His was the nature that inspired loyalty, commanded respect, won admiration from all. His kindly generous spirit prompted him to assist all who sought his counsel.

His death was a veritable loss to the Engineering Profession, to his colleagues, and to his many friends in whose thoughts his memory will ever linger as a true gentleman and a lovable character.

Mr. Spencer was elected an Associate Member of the American Society of Civil Engineers on August 31, 1915.

SAMUEL HOUSTON WARE, Assoc. M. Am. Soc. C. E.[1]

Died April 14, 1931

Samuel Houston Ware, the son of the late James Ware, was born at Fortress Monroe, Va., on October 26, 1879, where for many years his father was Chief Civilian Engineer.

Mr. Ware received the customary High School education and attended night school for three years, taking special courses in Engineering and Mechanical Drafting. Thereafter, he maintained a continuous study of engineering throughout his life.

He began work in 1899, and, as a civilian with the United States Engineer Department, in Norfolk, Va., supervised the fortification and river and harbor work in that vicinity until 1907. At this time, he was sent to Hawaii with Col. E. E. Winslow, U. S. Corps of Engineers, to construct emplacements for the 6-in. and 14-in. guns at Fort DeRussy. He also installed the fire-control system at Diamond Head, constructed the concrete wharf at Fort Armstrong, emplacements for guns at Fort Kamehameha, and many other projects. From 1915 to 1917, he was Superintendent on a land defense project, building land fortifications, redoubts, trenches, and anti-aircraft emplacements which required skillful engineering, due to location.

Mr. Ware was in command of Company I, Hawaiian National Guard, for three years, and, on June 1, 1918, when the Guard was called into active service, he was commissioned a Captain in the National Army of Engineers, and appointed Assistant to the District Engineer for the District of Hawaii. One year later, he was ordered to Camp A. A. Humphreys, Virginia, and, in 1920, accepted a commission in the Regular Army, transferring to the Quartermaster Corps.

---

[1] Memoir prepared by Maj. Henry Hockwald, Q. M. C., U. S. A., Fort Bragg, N. C.

Captain Ware served at the Army Base in Brooklyn, N. Y., for three years. During that time he was sent to Tobyhanna, Pa., as Constructing Quartermaster, where he remained for about three months. On his return to Brooklyn, he was sent to Newark, N. J., to close the Base Camp there.

From there Captain Ware went to California, serving as Transport Quartermaster on the United States Army Transport, *Cambrai,* for about six months. He was then ordered to the Presidio of Monterey, where he was stationed for three years, part of which time he was Post Quartermaster. He also served as Quartermaster for the Citizens Military Training Camp and the California National Guard Camp, at Del Monte, Calif., every summer, and was highly commended for his efficiency.

In 1927, he was ordered to Hawaii, where he served for three years at Fort Kamehameha. On completing this tour of duty, Captain Ware was ordered to Fort Bragg, North Carolina, where he remained for about three months. In March, 1931, he was ordered for duty as Constructing Quartermaster, at Fort Benjamin Harrison, Indiana. While driving to this station, with his family, they spent the night of March 14, 1931, at a hotel in Asheville, N. C., where he suffered a paralytic stroke. He was taken to the Mission Hospital, in Asheville, where he remained until his death on April 14, 1931. He was buried in Arlington Cemetery, Washington, D. C., with military honors.

While on duty at Fort Bragg, Captain Ware was Fire Marshal and in charge of the Post Utilities. In addition to these duties, he was Acting Quartermaster much of the time, which duty he performed most efficiently and satisfactorily to his superior officers. He was well liked by the employees working under his supervision, who regretted to see him leave this station, because of his exceptional fair treatment in dealing with them. Captain Ware was of an excellent character, and a very hard and efficient worker. He was a man of high moral character; delightful to meet, and well liked by every one.

He was married in 1910, to Mable McAndrews of Honolulu, who, with two sons, Everett Houston and Samuel Houston, Jr., survives him. He is also survived by two brothers, James E. Ware, Chief Clerk of the U. S. Engineering Department of Norfolk, Va., and Lieut.-Col. Joseph I. Ware, U. S. A. (*Retired*), of Dierdorf, Germany, and two sisters, Mrs. J. H. Cook, of Westbrook, Conn., and Mrs. J. B. Dennis, the wife of Capt. John B. Dennis, U. S. N., Assistant to the Chief of the Bureau of Medicine and Surgery, Navy Department, Washington.

Captain Ware was elected an Associate Member of the American Society of Civil Engineers on May 12, 1919.

CHARLES EDWARD WILLACKER, Assoc. M. Am. Soc. C. E.[1]

DIED NOVEMBER 4, 1930

Charles Edward Willacker, the son of Sylvia (Scisinger), and George D. Willacker, was born at Willard, Ohio, on May 25, 1888. His parents were native born; his mother's people came from Holland, and his father was of German descent. The Willacker family dated back to the Fifteenth Century, the coat of arms having been granted in 1493, by Kaiser Maximilian I, in the City of Worms, Germany.

---

[1] Memoir prepared by George A. Taylor, M. Am. Soc. C. E.

Mr. Willacker's boyhood was spent on a farm, and his early education was obtained in the common schools of Huron and Norwalk, Ohio. He attended a private night school, studying mathematics and engineering, and received a diploma from the International Correspondence Schools on the completion of a course in Surveying and Mapping.

In 1910, Mr. Willacker went to Toledo, Ohio, where he was employed by William H. Gould, Surveyor, as Rodman on city surveys, subdivisions, and construction work. The following year he acted as Instrumentman in Charge of Party on a similar detail. In 1912, he became associated with the late Joseph Hofman, M. Am. Soc. C. E., of Toledo, specializing in land surveys and real estate subdivision, and being licensed to practice in the State of Michigan.

His association with the Joseph Hofman Company continued throughout his life. At brief intervals, he was engaged as a Draftsman on airplane structures and on school heating plans. Subsequently, however, his successive positions with the Joseph Hofman Company were, as follows: 1912, Instrumentman and Inspector in charge of construction (paving and sewers); 1912-1916, Instrumentman in charge of party for city surveys; 1916-1924, Engineer in charge of city surveys, subdivision development, and construction (paving, sewers, walks, and culverts); 1924, in partnership with Mr. Hofman, as Engineer in charge of office and all other work coincident with his previous experience.

On the death of Mr. Hofman, in 1924, Mr. A. L. Hofman took over the interests of the business and, as a partner of the latter, Mr. Willacker continued as Engineer in charge of office and field work. He was later made Manager of the Company and was appointed Engineer for the Village of Sylvania, Ohio, which positions he held at the time of his death on November 4, 1930.

Mr. Willacker was a member of the Pilgrim Congregational Church, a Rotarian, an Odd Fellow, and a member of the Masonic Order, having been Eminent Commander of Lafayette Lytle Commandery. For seven years he was Scout Master of Boy Scout Troop No. 24. He was an enthusiastic supporter of all the organizations with which he was connected.

He was a loyal citizen and a careful and conscientious Engineer, held in high esteem by all his associates. He had many friends in every walk in life and was dearly loved by his family.

On November 6, 1912, he was married to Edna E. Clark, of New London, Ohio. He is survived by his widow, a three-year old son, Joseph Hofman Willacker, and by a brother, Elmer Willacker, of Cleveland, Ohio.

Mr. Willacker was elected an Associate Member of the American Society of Civil Engineers on November 15, 1926.

FERD CLARK WINTERMUTE, Assoc. M. Am. Soc. C. E.[1]

Died January 26, 1931

Ferd Clark Wintermute was born in the Charles Miner farmhouse on old River Road at Wilkes-Barre, Pa., on July 1, 1883, the son of Lemuel C. and Ida Ethel Belle (Mott) Wintermute. His father was a farmer, and a native, and a member of one of the oldest families, of the State of New Jersey.

Ferd Clark Wintermute grew up in his home town where he attended the public schools, but being filled with a desire to acquire more knowledge, he studied surveying and mapping by correspondence, and was tutored in higher mathematics and engineering. During his school days, he was employed as Time-Keeper for the Barber Asphalt Company. Later, he gained valuable experience in surveying and engineering with Mr. I. E. Hartwell, and the late N. B. Rutter, former County Surveyor for Luzerne County.

From 1902 to 1905, Mr. Wintermute served as Transitman and Assistant Engineer with the firm of Stevenson and Knight, of Scranton, Pa. After this experience, he was connected with the New York, New Haven, and Hartford Railroad Company as Assistant to the Engineer of Location, and served in that capacity until March, 1907. At this time he returned to Wilkes-Barre and opened an office in association with Mr. Fred A. Young, under the firm name of Young and Wintermute, Consulting and Civil Engineers. This partnership continued until Mr. Young's death in 1924. For a time, Mr. Wintermute remained in practice alone, but on January 1, 1927, Mr. Thomas J. Halsey entered the business with him under the name of Wintermute and Halsey. The members of the firm devoted their time largely to municipal and mining engineering, serving as Engineers for the Boroughs of Swoyerville and Kingston, Pa., and for the Central Coal Company and the Lehigh and Wyoming Valley Coal Mining Company; they were also employed as Civil Engineers for a number of realty companies, development concerns, and architects.

From 1909 to 1911, Mr. Wintermute served as Engineer in Hanover Township, Pennsylvania, on road and bridge construction; and in 1911 and 1912, he was Supervisor of field work on the construction of the Plymouth, Pa., Bridge; in 1913, he designed the steel and reinforced concrete for, and supervised the construction of, the Post Bailey Store and Office Building, in San Diego, Calif.; in 1914, he supervised the construction of the Crane Brothers Silk Mills, in Kingston, Pa.; and from 1917 to 1919, he served as Inspector of Municipal Improvements for the Wyoming Valley Taxpayers Association. He was employed as Resident Engineer for water supply improvements costing more than $2 500 000 for the City of Bayonne, N. J., in 1920 and 1921, and also designed and supervised the construction of the water supply filtration plant and sewers and sewage disposal plant for new buildings, for the Ranson District Poor Board.

---

[1] Memoir prepared by T. J. Halsey, Esq., Wilkes-Barre, Pa.

In 1921 and 1922, the firm designed and supervised the construction of the Lock Haven Steel Bridge, at Lock Haven, Pa., and from 1923 to 1925 was engaged on the design of original and revised plans for the proposed steel and reinforced concrete North Street Bridge, in Wilkes-Barre. In 1926, Mr. Wintermute made comprehensive plans for a sanitary sewer and storm drainage system for Kingston Borough. In 1927, he completed the building of the dam and the 60-acre Wyoming Lake Reservoir, in Franklin Township, Pennsylvania. At the time of his death, he was engaged as Engineer on the construction of a dam, roads, bridges, and other improvements on the Indian Lake Development of Stout-Roup, Incorporated, in the Pocono Mountains, in Pennsylvania, and a sanitary sewer system for the Borough of Swoyerville.

He was a Registered Professional Engineer and Land Surveyor of Pennsylvania and New Jersey, and from 1911 until his death in 1931, had been one of the Engineer Members of the County Board of Viewers of Luzerne County.

Mr. Wintermute was a member of Fidelity Lodge, No. 655, F. and A. M., of Wilkes-Barre; of Shekinah Chapter, No. 182, Royal Arch Masons; Dieu le Veut Commandery, No. 45, Knights Templars; Keystone Consistory, of Scranton, Ancient Accepted Scottish Rite Masons of the Thirty-Second Degree; and Irem Temple, Ancient Arabic Order, Nobles of the Mystic Shrine. He was a member of the Irem Temple Country Club, the Craftsmens Club, the Wyoming Valley Motor Club, and the Franklin Club, of Wilkes-Barre, and the American Water Works Association. He was also a member of the Junior Order of United American Mechanics, Patriotic Order of Sons of America, the Kiwanis Club, the Chamber of Commerce, and a Director and Vice-President of the Liberty State Bank and Trust Company, of Wilkes-Barre, and Director and Secretary of the Wilkes-Barre Mortgage Company. He was a member of the Westminster Presbyterian Church, of Wilkes-Barre.

On March 31, 1908, Mr. Wintermute was married to Jessie Archer Zundt, the daughter of Alexander and Elizabeth Zundt, of Brooklyn, N. Y. They had four children, Donald Stewart, Jack Lee, Lois Jean, and Janice Louise.

Mr. Wintermute was elected a Junior of the American Society of Civil Engineers on July 1, 1909, and an Associate Member on November 4, 1914.

THOMAS ROGERS HUGHES, Jun. Am. Soc. C. E.[1]

Died August 2, 1931

Thomas Rogers Hughes, was born at Oxford, Ohio, on September 30, 1902. He was graduated from Miami University, Miami, Ohio, with the degree of Bachelor of Arts in 1924, and continued his studies for the next two years at the Massachusetts Institute of Technology, from which he received the degree of Bachelor of Science in Civil Engineering.

On July 1, 1926, Mr. Hughes became a member of the Engineering Staff of the American Water Works and Electric Company and continued in this capacity until his death. For the past few years, he had supervised the selection and installation of a major portion of the electrical equipment in the pumping stations of plants controlled by the Company. His work in revamping the pumping stations of the Old Dominion Water Company, at Hopewell, Va., and The Wichita Water Company, at Wichita, Kans., was exceptionally well carried out. In addition, he superintended extensive improvements in the pumping stations of the East St. Louis and Interurban Water Company, at East St. Louis, Ill.

---

[1] Memoir prepared from information supplied by American Water Works & Elec. Co., Inc., and on file at the Headquarters of the Society.

Mr. Hughes was considered by his associates to be one of the most able and promising young men in the organization. His pleasing manner and marked degree of engineering ability made him a valuable asset to the Company's Engineering Staff, and his death was a great loss as he appeared to be just upon the threshold of a brilliant career in his chosen profession.

Mr. Hughes was a Junior of the American Society of Mechanical Engineers, and an active member of the American Water Works Association. His activities were not limited to engineering fields, as he was Chairman of the Scholarship Committee of the National Inter-Fraternity Group, the purpose of which was to raise the scholastic standing of college fraternities. Mr. Hughes was a member of Delta Kappa Epsilon Fraternity.

In October, 1930, he was married to Juliet Garrett, of Dongan Hills, Staten Island, N. Y. Mr. Hughes died suddenly of infantile paralysis at St. Joseph, Mo., on August 2, 1931. In addition to his widow, he is survived by his father, Dr. Raymond M. Hughes, President of Iowa State College, by his mother, and by a sister, Emily Hughes.

Mr. Hughes was elected a Junior of the American Society of Civil Engineers on November 15, 1926.

ELMER BARTHOLD LAWSON, Jun. Am. Soc. C. E.[1]

DIED OCTOBER 8, 1931

Elmer Barthold Lawson, the son of Frank H. and Jennie A. Lawson, was born in Minneapolis, Minn., on December 18, 1904. He obtained his early education there, including two years in the College of Engineering at the University of Minnesota. In 1925, he transferred to the Massachusetts Institute of Technology, at Cambridge, Mass., where he specialized in hydraulic and water-power engineering. He received the degree of Bachelor of Science from the Institute in June, 1927.

Following his graduation, Mr. Lawson was connected with the Randolph-Perkins Company, of Chicago, Ill., first as Resident Engineer in charge of the construction of a sewerage system in Hinsdale, Ill., and, later, he studied the phenomena of flood waves in channels. He was also engaged in the research work for a report on the 9-ft. channel for the Upper Mississippi

---

[1] Memoir prepared by F. I. Lawson, Esq., San Francisco, Calif.

River. As a result of his ability and resourcefulness in analyzing these problems through original thought, Theodore Brent, Consulting Engineer on waterways, requested his services, and Mr. Lawson became associated with Mr. Brent in New Orleans, La., in February, 1929.

This work, which covered the period until his health failed in March, 1931, had to do with economic and engineering surveys connected with the development of water transportation on the Mississippi River and its tributaries, as well as the development of interchange terminals, and work in preparation of important cases before the Interstate Commerce Commission.

Both his employers have remarked about Mr. Lawson's ability to couple a highly trained engineering mind with the practical requirements of the problems put before him. In addition, he developed a personality which made friends even with those whose assertions it became necessary to modify, unobstrusively ingratiating himself with others so that his untimely illness and passing are deeply felt by all those who came in contact with him.

Mr. Lawson was elected a Junior of the American Society of Civil Engineers on November 14, 1927.

BERNARD JOSEPH MERICKEL, Jun. Am. Soc. C. E.[1]

Died December 21, 1931

Bernard Joseph Merickel was born in Toledo, Ohio, on February 14, 1902, the son of the late George Joseph and Theresa Merickel.

Mr. Merickel attended the grade school and the Jessup W. Scott High School, in Toledo. He matriculated at the Ohio State University, at Columbus, in 1922, from which he was graduated with the degree of Bachelor in Civil Engineering on June 15, 1926. During the vacation periods of 1924 and 1925, he was employed in the office of Mr. Fred L. Kuebler, in Toledo, on miscellaneous surveys.

Following his graduation, Mr. Merickel entered the service of the Building Products Company, in Toledo, as Designer and Detailer on structural iron work, serving until the fall of 1926, when he entered the City Engineer's office, as Assistant Engineer in charge of concrete analysis, which position he held until the fall of 1927.

He then joined the Engineering Department of the New York Central Railroad Company, serving as Transitman until June, 1930. At this time, he was appointed an Assistant Engineer, with the Ohio State Highway Department. In July, 1931, he was given a leave of absence on account of ill health, and he died five months later.

Mr. Merickel was married, on June 18, 1927, to Helen Miller, whom he had met when they were students at the Ohio State University, and who, with a young daughter, Marylin, survives him.

---

[1] Memoir prepared by George Champe, M. Am. Soc. C. E.

He was a member of the various Masonic organizations, including the Scottish Rite and Zenobia Shrine. He was also a member of the Chi Phi Fraternity.

It was the privilege of the writer to have known Mr. Merickel from his early boyhood and to have watched, with much interest, his uniform advancement through the schools and University and his increasing interest and advancement in engineering experience, his activities in civic affairs, and his devotion to his home and family.

Mr. Merickel was elected a Junior of the American Society of Civil Engineers on October 1, 1926.

JOHN HARRY MILLER, Jun. Am. Soc. C. E.[1]

DIED OCTOBER 14, 1931

John Harry Miller, the son of John Harry and Catharine (Kearney) Miller, was born in Philadelphia, Pa., on October 24, 1902. His mother was a native of County Donegal, Province of Ulster, Ireland, where she spent her childhood days and her girlhood. His maternal grandparents were of Northern Ireland stock and lie buried beside Doe Castle, a famous landmark in County Donegal. His paternal grandparents were early settlers of Oxford County, Pennsylvania, and his father was born in the Town of Oxford.

Mr. Miller attended the public schools of Philadelphia, and was graduated with honors from the West Philadelphia High School in June, 1921, despite having left school to work for a year in the shipyards at Hog Island, Philadelphia. He entered Drexel Institute, Philadelphia, in September, 1921, and had completed one year's work at the time of his father's death, in 1922. He then left school and became a Machinist at the Baldwin Locomotive Works, in Philadelphia, which position he held until September, 1923.

Through the interest of his good friend, Mr. Thomas B. Donaldson, he obtained a scholarship at the University of Pennsylvania, and in September, 1923, he enrolled in the Civil Engineering Course in the Towne Scientific School. In addition to making a creditable record in his scholastic work, Mr. Miller also engaged in athletics to the fullest extent of his allowable time. He played football all four years of his college career, receiving the coveted Varsity award, the "P." He also rowed on the crew for the University and received the Junior Varsity award. He was elected to the Honorary Engineering Society, Tau Beta Pi, in the fall of 1926, in recognition of his high scholastic standing and well-rounded undergraduate life. He was also a member of the Delta Sigma Phi Fraternity and of the Varsity Club. He was graduated in June, 1927, with the degree of Bachelor of Science in Civil Engineering

Immediately after his graduation, Mr. Miller entered the employ of the Austin Company, of Cleveland, Ohio, as Engineer of lines and grades on the construction of an industrial building in Baltimore, Md. After the completion of this building and another in Newark, N. J., on which he had been engaged, the shortage of current work caused him to leave this Company and enter the employ of Engstrom and Wynne, in the same capacity, on the construction of a new unit for the Bryn Mawr Hospital, in Bryn Mawr, Pa. When this project was completed, he became Field Engineer on the construction of the new Maternity Building of the Pennsylvania Hospital, in Philadelphia.

---

[1] Memoir prepared by Charles S. Doerr, Jun. Am. Soc. C. E.

Following the completion of this latter program, he entered the employ of Fuller and McClintock, Consulting Engineers, of Philadelphia, as an Office Engineer and Designer, principally on hydraulic and sanitary installations. However, Mr. Miller was by nature and training a rugged, outside construction man, and was not happy in this connection due to the close confinement of office work. Consequently, he went to the Stone and Webster Corporation in the capacity of Field Engineer on the construction of buildings for the Westinghouse Lamp Company, at Nutley, N. J. This project was about finished when the Austin Company sent for him to return as Resident Engineer and Superintendent on the construction of the Frederick Brant Rentschaler Airport, affiliated with the Pratt and Whitney Aircraft Company and the Chance-Vought Corporation, in East Hartford, Conn. This airport was one of the largest in the Eastern United States, and included several features unique in their types, at the time of their installation. Following this project, Mr. Miller was engaged for a time on a municipal airport for Scranton, Pa., being built by the Austin Company. He was erecting an industrial building for this Company at Hawthorne, N. J., and was in the performance of his duties when he met his untimely death.

Mr. Miller's experience in airport construction had developed him into a valuable engineer and superintendent and, no doubt, he would have become an expert in this field in latter years. He inherited from his greatly admired mother a keen wit, an alert mind, and a strong sense of humor that made him a most congenial companion. He learned from his early association with his father to develop a wholesome interest in all topics and in people in general, and he often referred to his father's wise counsel. His father had made a practice of taking his son on long walks and had thereby developed a real friendship between them, which Mr. Miller always cherished.

He was a composite type of American manhood, clear-thinking, clean-minded, athletically active, strong-bodied, fearless, and possessed of the highest ideals from which he never swerved. He held the esteem and respect of his fellow men and was genuinely liked by all with whom he came in contact. He knew how to be and was a true friend; he also had true friends, and he was loyal to them always. The world has lost a real man and the profession has lost a capable engineer, while those who knew him best, have only an immortal, wistful memory.

On October 17, 1930, he was married to Margaret Dill, of Philadelphia, and is survived by his widow, his mother, and two sisters, Irene (Miller) Wilson and Sara (Miller) Wanner.

Mr. Miller was elected a Junior of the American Society of Civil Engineers on December 5, 1927.

WILLIAM JOSIAH KARNER, Affiliate, Am. Soc. C. E.[1]

DIED SEPTEMBER 21, 1931

William Josiah Karner, son of Pliny and Eliza (Bacon) Karner, was born at South Egremont, Mass., on January 10, 1840. He had two sisters, Lucy and Sarah, and one brother, Andrew. He was educated in the "Little Red Schoolhouse" at South Egremont, and at Hudson River Institute, Claverack, N. Y. A report from the latter school to Mr. Karner's parents shows a grade of 100 in all his studies, and remarks that "William should become one of the best school teachers in the State." However, Mr. Karner, after a short trial of country school teaching, turned to a commercial life.

In 1862 and 1863, during the Civil War, Mr. Karner was a Corporal in Company E of the 49th Regiment, Massachusetts Volunteer Militia, and was honorably discharged on account of illness. In January, 1865, he was appointed to a first-class clerkship in the Government Post Office at Washington, D. C., but ten months of routine desk work was too much for an active man and he resigned to accept a clerical position in New York, N. Y. In 1869, he moved to Hannibal, Mo., where he was engaged for four years in the lumber business.

In February, 1873, Mr. Karner formed an association with the late E. L. Corthell, Past-President, Am. Soc. C. E., which lasted twenty-three years, on engineering and construction work throughout the United States, in Mexico, Central America, and South America. One of their early works in 1873, 1874, and 1875, was the construction of the Sny Levee on the east or Illinois bank of the Mississippi River and of a bridge across that river at Louisiana, Mo., with a draw span 444 ft. long, at that time the longest in the world. From July, 1875, to May, 1880, Mr. Corthell, as Chief Engineer of Construction, and Mr. Karner, as Purchasing Agent and Cashier, were associated with the late James B. Eads, M. Am. Soc. C. E., in the construction of the South Pass Jetties at the mouth of the Mississippi River which, by the opening of a 30-ft. channel into the Gulf of Mexico, made the Mississippi accessible to ocean-going vessels.

From September, 1880, to August, 1881, Mr. Karner was an active partner on a construction contract from the United States Government for the protection of a section of the Mississippi River bank between Baton Rouge and New Orleans, La., and was in charge of this work for six months. From October, 1881, to July, 1884, he was Office Assistant and Secretary of the North River Construction Company which held the contract for financing and constructing the West Shore Railroad from Weehawken, N. J., to Buffalo, N. Y., and the Weehawken Tunnel and Terminal. The late Walter Katté, M. Am. Soc. C. E., was Chief Engineer of the Construction Company and Mr. Corthell, Chief Engineer of the Railroad Company in charge of the work. In October, 1884, Mr. Karner joined the Eads Concession Company, of which

---

[1] Memoir prepared by Lincoln Bush, Past-President, Am. Soc. C. E., and S. Dewey Brown, Assoc. M. Am. Soc. C. E.

Mr. Eads was President and Mr. Corthell, Chief Engineer, and served until May, 1887, as Secretary of the Company and Private Secretary to Mr. Eads. This Company was formed to make the surveys and studies for a projected ship railway across the Isthmus of Tehauntepec and obtained a concession for it from the Mexican Government, but on Mr. Eads' death, in 1887, the project was dropped.

From May, 1887, to May, 1889, Mr. Karner was Chief Clerk in charge of accounts and estimates in the Chicago Office of the late George S. Morison, Past-President, Am. Soc. C. E., and Mr. Corthell, engaged in designing and constructing railroad bridges over the Ohio, Missouri, and Mississippi Rivers, including the Ohio River Bridge at Cairo, Ill., for the Illinois Central Railroad, then the longest steel bridge in the world. Among the engineers in the employ of Messrs. Morison and Corthell at this time was Ralph Modjeski, M. Am. Soc. C. E. From May, 1889, until Mr. Corthell's retirement from active practice in the summer of 1895, Mr. Karner was the former's Assistant on many important engineering and construction projects, including the improvement, by means of jetties, of Tampico Harbor, at the mouth of the Panuco River, Mexico, the Merchants Bridge at St. Louis, Mo., improvements at the mouth of the Brazos River in Texas, and a joint entrance into the City of Chicago for the Atchison, Topeka, and Santa Fé Railroad and a subsidiary of the Illinois Central Railroad.

In 1895, Mr. Karner went as Assistant and Chief Clerk to the late John F. Wallace, Past-President, Am. Soc. C. E., Chief Engineer of the Illinois Central Railroad, and continued to hold the same position under David Sloan, M. Am. Soc. C. E., when the latter succeeded Mr. Wallace. In 1903, Mr. Karner resigned his position with the Illinois Central Railroad Company and joined Mr. Modjeski, at that time Engineer in charge of the construction of a railroad bridge across the Mississippi River, at Thebes, Ill. In 1904, when Mr. Wallace was appointed by President Roosevelt as the first Chief Engineer of the Isthmian Canal Commission, Mr. Karner went with him to Panama as Resident Engineer and, in June, 1905, was appointed Special Disbursing Agent. From this time, until his resignation in July, 1909, Mr. Karner had charge of recruiting and shipping to the Canal Zone laborers from Barbados and certain other West Indian Islands, and, later, from Spain and other European countries. From 1909 to 1921, Mr. Karner was Director, Secretary, and Treasurer of Bowne and Company, Incorporated, New York, printers and manufacturers of commercial stationery, retiring on October 31, 1921, from which time until his death he made his home at Danville, Ill., with Federal Judge Walter C. Lindley whose wife is a niece of Mrs. Karner.

It is a remarkable fact that Mr. Karner was associated in service with three Presidents of the Society, namely, George S. Morison, John F. Wallace, and Elmer L. Corthell, and with one Vice-President, James B. Eads.

Mr. Karner was widely known for his excellent reputation and integrity and for his capable executive ability, gracious personality, and his loyalty to his friends and associates. He always had a great interest in young men, and while with the Illinois Central Railroad Company he instituted a "Track

Apprentice" system which many present-day engineers will remember as being their start in the Civil Engineering Profession. He was a member of the Western Society of Engineers, the New England Society of New York, the Visiting Women's Press Club of New York, the Thursday Morning Club of Great Barrington, Mass., and was a Mason, an Elk, and a Kiwanian, a Congregationalist in religion, and a Republican in politics.

On January 25, 1871, he was married to Maria Louise Dewey, of North Egremont, Mass., who died on September 11, 1917. They had no children.

Mr. Karner was elected an Affiliate of the American Society of Civil Engineers on July 2, 1890.

EDWARD ALFRED SIMMONS, Affiliate, Am. Soc. C. E.[1]

Died September 30, 1931

Edward Alfred Simmons, the son of John Wesley and Agnes Anne (Owers) Simmons, was born on March 20, 1875, in Brooklyn, N. Y.

He attended the public schools of that city only as far as the Grammar Grades, for at the age of fourteen it became necessary for him to help support his widowed mother. Through the recommendation of his Sunday School teacher he secured employment as a counter clerk in the department store of A. D. Mathews and Son, in Brooklyn, which employment paid him $1.50 per week. He did not remain long at this post, however, as one of the members of the choir of St. Mary's Protestant Episcopal Church, in Brooklyn, in which he sang, informed him that he could get $5.00 per week with The Railroad Gazette.

His first job with the Company which he later controlled, was as a clipper of news items. He was rapidly promoted to Assistant to the News Editor, Advertising Make-up Clerk, Advertising Solicitor, Western Manager, with headquarters in Chicago, Ill., Secretary, Treasurer, Director, Vice-President, and (from 1911) President. In 1912, the corporate name of this Company was changed to Simmons-Boardman Publishing Company. It numbers among its publications the *Railway Age, Railway Signaling, Railway Mechanical Engineer, Railway Electrical Engineer, Railway Engineering and Maintenance, Marine Engineering and Shipping Age,* and *The Boiler Maker;* as well as three technical encyclopedias and numerous books. Its widely known slogan name, "The House of Transportation," was originated by Colonel Simmons. In 1928, the American Builder Publishing Corporation was purchased and Colonel Simmons was elected Chairman of the Board. Its principal publication is now known as *American Builder and Building Age.* Both these companies were taken over later in the same year by a new holding company, called the Simmons-Boardman Publishing Corporation, of which Colonel Simmons was President.

---

[1] Memoir prepared by Jessica Husk, New York, N. Y., Executive Secretary to the late Colonel Simmons.

An authority of international reputation on rail and water transportation, Colonel Simmons was appointed by two Presidents of the United States as a Government Delegate to International Railway Congresses, the first at London, England, in 1925, and the second at Madrid, Spain, in 1930. He was also designated a Delegate on the part of the United States to the Fifth International Congress of Building and Public Works, held in London, in May, 1930.

As President of the American Marine Association he was an outspoken advocate of the development of a great merchant marine for the United States, and the achievements of the American Marine Standards Committee, which organization he founded, are largely due to his capable guidance as Chairman of its Executive Board.

Industrial interests were also his. In 1904, he organized the American Saw Mill Machinery Company with a plant at Hackettstown, N. J., and served thereafter as its executive head. The Company has two subsidiaries, the American Saw Works and the American Machine Tool Company.

He heard the call of his country at the time of the World War and was commissioned, in February, 1918, a Major in the National Army. He served as Regional Constructing Quartermaster until February, 1919, in charge of all new Army construction work in and around New York Harbor, except the Brooklyn Army Base, having at one time twenty-two projects under his supervision. Among them were the $2 500 000 General Hospital, at Fox Hills, Staten Island, four different sets of barracks, a coal trestle, a dock, an engine house, an aviation field, a repair pit, a garage, an incinerator, and a fresh-water supply line.

His work in this connection was highly praised by Brig.-Gen. R. C. Marshall, Jr., U. S. A., M. Am. Soc. C. E., Chief of the Construction Division, in a citation which read:

> "A spirit of loyalty and competent effort has characterized your service in the Construction Division and was particularly helpful in the successful prosecution of the largest war construction program ever undertaken."

His transfer to the Engineer Corps, with detail for service with the American Military Railways in France, was in process of consummation when the Armistice was signed.

In 1918, he was commissioned a Lieutenant Colonel in the Quartermaster Section of the Officers Reserve Corps; in 1922, he was promoted to the rank of Colonel; and recommissioned in 1927, which commission ran to November 8, 1932.

Colonel Simmons' activities in the American Legion began in 1919 when he helped to organize several posts. He was elected Commander of Kings County Post No. 500 (now Brooklyn Post No. 500) and commanded the Kings County Organization of the Legion for two terms. He had charge of the funeral services at the Brooklyn and Hoboken piers for the soldiers brought from France for reburial in this country. For several years he served on the National Transportation Committee of the Legion. He was Treasurer of Construction for Division Post No. 10 at the time of his death.

He took an active part in organizing the Citizens' Military Training Camp Clubs and was untiring in his efforts in behalf of Reserve Officers, having twice served as President of the Brooklyn Chapter of the Reserve Officers' Association of the United States, and was discharging the duties of that office for the Department of New York at the time of his death. Other military organizations of which he was an active member were: The Construction Division Association; Military Order of the World War; New York Society of Military and Naval Officers of the World War; Society of American Military Engineers; and Quartermasters' Association.

The career of Colonel Simmons was conspicuous in civil as well as industrial and military service. He was a member of the Board of Regents and Treasurer of the Long Island College Hospital from 1914 to 1922. Here, he had studied medicine in 1908, principally before working hours in the morning, with no idea of becoming a physician, but with the thought of devoting his knowledge to charity. He had accepted the Chairmanship of a commission appointed to provide an adequate water supply for the Town of Inlet, N. Y., adjacent to his country home, "Albedor," situated at Eagle Bay on the fourth of the Fulton Chain of Lakes, where he spent as much time as business permitted. Always a zealous American, he offered gold, silver, and bronze medals to school children for the three best essays selected in competition on such subjects as "The American Flag" and "Why I Love America"; and frequently presented schools with large American flags. His philanthropies were many.

Colonel Simmons was an Associate Member of both the American Society of Mechanical Engineers and the Society of Naval Architects and Marine Engineers, and Chairman of the Endowment Committee of Engineering Foundation, Inc.

While a registered Republican, and a member of the Union League Clubs of both New York and Brooklyn, Colonel Simmons always supported a candidate rather than his party, and numbered many Democrats among his friends. As one of the foremost leaders of the business press, he was selected to head the Business Paper Publishers' Committee which successfully campaigned for President Hoover in 1928. He was once mentioned as a possible candidate for Borough President of Brooklyn, but gave his supporters no encouragement.

Colonel Simmons took an active interest in winter sports, donating a silver loving cup to the American Legion of Old Forge, N. Y. An ardent fisherman himself, he served as Honorary President of the New York State Division of the Izaak Walton League of America. He was also an enthusiastic golfer and was prominently identified with the activities of the Inlet Golf Club, Inlet, N. Y. The Adirondack League, Old Forge, N. Y., the Thendara Golf Club, Thendara, N. Y., the Engineers' Club, Roslyn, Long Island, and the Congressional, Washington, D. C., were among his country clubs. His name was also on the membership roll of a number of New York City clubs, including the Army and Navy, Automobile, Bankers', and Engineers'; and, for several successive terms, he was a Governor of the Railroad Club.

A Thirty-second Degree Mason, and a member of the Benevolent and Protective Order of Elks, his fraternal orders were: Aurora Grata Consistory; Clinton Commandery; Kismet Temple; Long I Grotto; Orient Chapter; Mistletoe Lodge (F. and A. M.), and Brooklyn Lodge 22 (B. P. O. E.).

Scheduled to attend the Washington Conference of the President's Committee on Home Building and Home Ownership the following day, Colonel Simmons was in the Pennsylvania Railroad Station, New York City, on the night of September 29, 1931, when he was taken ill. The following evening he died at his home in Brooklyn, of cerebral hemorrhage. Having come into the world simply, he passed out of it with simple, but impressive, services at his residence. However, full military honors were accorded him en route to his final resting place in Greenwood Cemetery, Brooklyn, with Reserve Officers acting as Honorary Pallbearers and a detachment from Fort Hamilton firing a farewell salute as "Taps" was sounded.

Among the numerous floral tributes was a wreath sent by special messenger from President Hoover, with a letter in which he said:

> "I am greatly shocked to learn of the death of Colonel Simmons, who had long been my friend. He had a distinguished career of public service and his passing is indeed a great loss."

Professor Arthur T. Hadley, before he became President of Yale University, said of Colonel Simmons:

> "It has been my fortune to know many men to whom journalistic responsibility attached, but never one who more sedulously was devoted to the belief that out of ill there would come good. He was not impulsive, he was not voluble; but as an optimist, in the higher sense of living optimism, he was action perfect."

Following twenty years of association, Samuel O. Dunn, Editor-in-Chief of the publications of the Simmons-Boardman Publishing Corporation, wrote:

> "Colonel Simmons never issued a single order that any editorial, article or item should be published in or omitted from one of these papers, or that any editorial policy should be adopted, changed or abandoned. His course in this respect was not dictated by expediency, but by principle. Like every publisher, he desired that the company of which he was the head should be financially successful. His fundamental principle as a publisher, however, was that a business paper should be published primarily to render the greatest possible service to the industries in the field that it covered. He believed that such service could be rendered only by a paper that published the most complete and accurate information that it could get regarding all the developments in the field, and that boldly criticized unsound policies and advocated sound policies, regardless of any fears that might be felt as to the probable effects upon its circulation and advertising. He never once failed unflinchingly to support his editorial department when convinced that the editors themselves were satisfied as a result of adequate investigation and study that the policies they were following were sound from the standpoint of the interests of the industries the papers were undertaking to serve. If the various Simmons-Boardman papers have been outstanding in the services they have rendered to the business fields that they have undertaken to cover, the credit has been mainly due to Colonel Simmons' courage and public spirit as a publisher."

And so, this able publisher, manufacturer, soldier, civic worker, and sportsman, actuated by the highest motives, and with the utmost consideration for his associates, despite a lack of technical training, achieved unusual prominence. Colonel Simmons will long be remembered in the words of Ward Gedney, as "frank, cordial, but unfailingly serious; smiling with the warm smile of a man big physically, mentally and morally, but slow to smile."

He was survived by his widow, Ida Rines Simmons, to whom he was married on October 12, 1914, and their three daughters, Aline, Doris, and Elizabeth.

Colonel Simmons was elected an Affiliate of the American Society of Civil Engineers on October 14, 1919.

EDWARD DEAN ADAMS, F. Am. Soc. C. E.[1]

Died May 20, 1931

Edward Dean Adams, the eldest son of Adoniram Judson Adams and Harriet Lincoln Norton Adams, was born in Boston, Mass., on April 9, 1846. He was a lineal descendant of Henry Adams of Braintree, Mass., who came to America from Somersetshire, England, in 1638, and whose descendants included two early Presidents of the United States, John Adams and John Quincy Adams.

Graduating from Norwich University at Northfield, Vt., in 1864, as a Bachelor of Science, Mr. Adams spent fifteen months traveling in France, Italy, Greece, Turkey, Palestine, Egypt, and Spain. Returning to America, he studied at the Massachusetts Institute of Technology during the college year, 1865–1866, as a member of the Class of 1869 in Engineering and Architecture. The year following was devoted to practical experience in all departments of a paper mill in Berkshire, Mass., with some thought of engaging in this industry. Study was continued after leaving the Institute, with special attention to accounting and business management, developing aptitude for analysis of accounts.

Mr. Adams began his business career in 1866 in Boston as Bookkeeper and Cashier of Thomas J. Lee and Hill, Stock Brokers, soon representing the firm as member of the Stock Exchange. In 1870, the Middle West attracted him. He selected Appleton, Wis., for its water-power possibilities and other natural resources and organized a bank there; but a Boston friend dissuaded him from settling in the West. Instead, he joined this friend and another in establishing in Boston the banking house of Richardson, Hill and Company.

In 1878, Mr. Adams removed to New York, N. Y., and became a partner in the banking house of Winslow, Lanier and Company. This connection was maintained for fifteen years. From 1893 to 1914, he was American representative of the Deutsche Bank of Berlin. In his seventy-fifth year, he curtailed his business interests, in order to devote energies to the fine arts and sciences in which he had long been particularly interested.

---

[1] Memoir prepared by Lewis B. Stillwell, M. Am. Soc. C. E.

During fifty-four years in business, Mr. Adams was an officer or director in more than forty corporations engaged in transportation, manufacture, power development, or other enterprises. His constructional and financial aptitudes manifested themselves in combination throughout his business activities, and in numerous voluntary public services. His business undertakings embraced organization, re-organization, or development of the New York, West Shore and Buffalo Railroad, Central Railroad of New Jersey, Northern Pacific Railroad, two railroads in Mexico, Cataract Construction Company, The Niagara Falls Power Company, East Jersey Water Company, All America Cables, Incorporated, Allis-Chalmers Company, American Cotton Oil Company, Edison Electric Illuminating Company, Hammond Typewriter Company, Davis Coal and Coke Company, Union Petroleum Company, Bullock Electric Manufacturing Company, and many more. These transactions involved hundreds of millions of dollars and tens of thousands of bondholders, stockholders, and employees, and necessitated thorough familiarity with the industries of the entire United States. Under a concession from the Mexican Government, Mr. Adams and a few associates for several years minted much of the coinage of that country.

Greatest of the services by Mr. Adams to his country was his leading part in preventing suspension of specie payment in President Cleveland's second term, threatening as an outcome of the "free silver" fallacy. On January 8, 1896, the Deutsche Bank conferred,

> "Special power of attorney unto Edward D. Adams to enter into an agreement on our behalf with the Secretary of the Treasury of the United States of America for the sale and delivery to said United States of a certain quantity of gold payable in United States 4 per cent 30-year coupon or registered bonds, part of a total not exceeding two hundred millions of dollars nominal capital, and we authorize the said Edward D. Adams to stipulate on our behalf and in his discretion all conditions of said agreement."

With this backing Mr. Adams invited Messrs. J. Pierpont Morgan and James Stillman to join him in a syndicate with Mr. Morgan as Manager, each of the three subscribing $25 000 000. A contract was made with the Government. An issue of 4% bonds, due in 1925, was fivefold over-subscribed by the public. A shipment of several million dollars in gold from Germany was arranged to meet immediate needs and restore confidence. On February 21, 1896, the gold reserve was re-established in excess of $100 000 000; it had fallen to $31 862 000 on January 31. Suspension would have staggered industry and commerce.

Mr. Adams' interest in science and in engineering development led him to take keen interest in Edison's invention of the electric lamp and the establishment of the first electric lighting central station.

In 1885, the late William B. Rankine, brought to the attention of a group of New York capitalists and bankers a charter for the development of power at Niagara Falls. Among the early members of this group were D. O. Mills, John Jacob Astor, Edward A. Wicks, Francis Lynd Stetson, and Mr. Adams. These gentlemen decided to form a corporation to undertake the enterprise, and selected Mr. Adams as executive leader. The Cataract Construction Company was organized with Mr. Adams as President, and the comprehensive and exhaustive investigation of possible methods of developing and utilizing the power of Niagara which he directed during the years immediately following, is a classic among researches in the field of engineering.

The development of power on a large scale at Niagara Falls by hydroelectric equipment and the transmission of this power in the form of alternating current by electrical conductors to distant points of use, attracted universal attention and established the confidence of investors and of the public in this far-reaching development of applied science. So pervasive of all engineering, industrial, communal, and household operations have been the results of this pioneering large-scale work at Niagara that the generation since born little realizes the boldness of that forward step, the immaturity of the sciences and arts upon which success depended at the time when it was taken, or the courage it demanded amid diametrical divergences of opinion among acknowledged scientific and engineering leaders. To-day, 96% of the electricity utilized in the United States is generated as alternating current and all long-distance transmissions of power are by alternating current at high potential.

When attacking the Niagara problem, Mr. Adams retained the late Coleman Sellers, M. Am. Soc. C. E., of Philadelphia, Pa., a mechanical engineer of great ability, sound judgment, and long experience, and accompanied by him traveled extensively seeking the advice of the foremost engineers and scientists in both America and Europe. The problem was presented to those whom he consulted in its broadest aspects. Here was a vast amount of undeveloped hydraulic power. Its utilization, of course, involved the use of some type of hydraulic turbine. How should the mechanical power at the shafts of the turbines be utilized—by direct connection or by some form of transmission—by belts or cables, by compressed air, by hydraulic transmission, or by electrical transmission?

To make sure that the great enterprise should have the benefit of the latest advances, five distinguished scientists and engineers were invited to be the members of the International Niagara Commission, to determine the forms of applications of the latest knowledge to the "harnessing of Niagara." Sir William Thomson (later, Lord Kelvin) was Chairman; his associates were Dr. Coleman Sellers, of Philadelphia, Lieut.-Col. Theodore Turrettini, of Geneva, Switzerland, Professor E. Mascart, of the College of France, and Professor William Cawthorne Unwin (now Hon. M. Am. Soc. C. E.), of London, Secretary. This was the first known inter-continental council of leaders in scientific fields to consider practical applications of the physical sciences to an industrial project of international interest.

It was inevitable and of course expected that among the many engineers consulted who were not members of the Commission there should be wide divergence of opinion and advice. Even when the Commission reached the conclusion that electricity should be used to transmit and distribute power from a central station, some of its members advocated direct current while others believed that alternating current should be adopted. Throughout this difficult period of investigation, the great interest of Mr. Adams in science and engineering, his vision, sound judgment, wonderful tact, and systematic methods guided his Company to a conclusion which has abundantly stood the test of time and experience.

The 5 000-h. p. turbine and generator on the same shaft built for Niagara Falls Power House No. 1, constituted a unit of unprecedented magnitude. The ten units there installed became the progenitors of the 82 000-h. p. units placed in operation at Niagara Falls in 1914. The 22-mile transmission line of 1896 to Buffalo, N. Y., at 11 000 volts tension, with transformers arranged so that 22 000 volts could be used when adequate line insulators might become available, pointed the way to the numerous high-tension lines since erected in many parts of this country, scores, and even hundreds, of miles long, at voltages up to 220 000, being increasingly linked together to form super-power networks, each dependably serving industries and communities in several States.

The installation thus constructed under Mr. Adams' executive leadership was the first central station in America built and equipped for the purpose of developing and distributing power in the form of electric energy—a conception which has contributed greatly to economy, convenience, and dependability in the production and delivery of power whether generated from falling water or from fuel. The story of the development of power at Niagara Falls has been told by Mr. Adams in a work of two volumes, entitled "Niagara Power."

In April, 1926, the John Fritz Medal, esteemed the highest recognition in the gift of the Engineering Profession in the United States was conferred upon Mr. Adams "for great achievements as Engineer, Financier, Scientist, whose vision, courage and industry made possible the birth at Niagara Falls of hydro-electric power."

A service of peculiar and enduring interest to the Engineering Profession was rendered by Mr. Adams only a few years before his death. In 1927, while representing Engineering Foundation at the celebration of the Five Hundredth Anniversary of the founding of the University of Louvain, in Louvain, Belgium, he conceived the idea that a clock and carillon for the tower of the University Building, the reconstruction of which by contributions from America was then approaching completion, would constitute a fitting memorial to the American Engineers who lost their lives in the World War. His idea was adopted by the American Society of Civil Engineers, the American Society of Mechanical Engineers, the American Institute of Electrical Engineers, and the American Institute of Mining and Metallurgical Engineers, and, under Mr. Adams' personal direction, was carried through to completion most effectively in every detail. The carillon of forty-eight bells and the beautiful and symbolic design of the four faces of the great clock constitute a memorial, than which none can be more beautiful or appropriate.

During and notwithstanding his prolonged and intense business activity, Mr. Adams for many years was a patron of Astronomy, particularly interested in total eclipses of the sun. Through his personal co-operation the first paintings of the corona in its true colors were made at Baker, Ore., in 1918, by the distinguished artist, Howard Russell Butler, as a part of the official observations by the Naval Observatory Staff.

The breadth of Mr. Adams' interests in engineering, science, the fine arts, education, and philanthropy, is attested by mention of his active connections with the American Society of Civil Engineers, American Institute of Electrical Engineers, Engineering Foundation, Engineering Societies Library, National Research Council, American Museum of Natural History, New York Botanical Garden, Metropolitan Museum of Art, American Numismatic Society, Institute of Musical Art in the City of New York, Columbia University School of Business, American Scenic and Historical Preservation Society, American Academy in Rome, and American Committee for Devastated France. This list is far from complete; it includes none of the fifty or more organizations of which he was merely a member, nor his twenty-eight clubs. These facts evidence a rare scope of industrial, financial, and scientific achievement, both by personal effort and by support of other workers, coupled with an extraordinary number and diversity of human contacts.

Mr. Adams was an active member of the Protestant Episcopal Church and, for many years, was Senior Warden of the Parish of St. George, Rumson, N. J.

His Alma Mater, Norwich University, conferred upon him the degree of Master of Science (M.Sc.) in 1897, Doctor of Laws (LL.D.), in 1906, Master of Arts (M.A.), in 1908, and Doctor of Science (Sc.D.), in 1927. Honorary degrees of Doctor of Science were conferred upon him in 1928 by the University of Louvain and in 1930 by Columbia University.

During his remarkable career, Mr. Adams was invested by Foreign Governments with the following honors: Royal Order of the Crown of Prussia, Second Class, 1909; Medaille de Reconnaissance (with silver star), of the French Republic, 1921; John Fritz Gold Medal, 1926; Commander of the Order of the Crown (of Leopold) of Belgium, 1928; Chevalier de l'ordre National de la Legion d'honneur (France), 1929.

In 1872, Mr. Adams was married to Frances Amelia Gutterson, of Boston, who died in 1921. He is survived by a daughter, Mrs. Leighton Lobdell, by a granddaughter, Brenda Lobdell, and by four grandsons, Francis Lobdell, Leighton Mansfield Lobdell, Pierpont Adams, and Kempton Adams.

In physique, Mr. Adams was below the average height, slender rather than stout even in his old age. His bearing was always dignified, but his manner was urbane and courteous. His head was large and his features, especially his large and luminous eyes, strikingly evidenced his character and great ability. His mind was highly analytical and methodical. His mental activity was incessant, and although he examined with great care each factor of a problem, however complicated, he visualized with accurate perspective the problem as a whole. In expressing his views orally or in writing, he was deliberate, clear, and precise. It is safe to say that few men, if any, of his generation have excelled him in intellectual grasp of essential premises or in logical ability to draw sound conclusions from those premises.

Mr. Adams was elected a Fellow of the American Society of Civil Engineers on March 31, 1891.

Titles of papers are in quotation marks when given with the author's name.

VOLUME 96

SUBJECT INDEX

ADDRESSES.

Presidential Address at the Annual Convention at Yellowstone National Park, Wyoming, July 6, 1932. Herbert S. Crocker. 1380.

AIR FLOW.

Models of airplane propellers. 301.

AIRPLANE PROPELLERS.

Models of —. 301.

ARCHES.

"Design of a Reinforced Concrete Skew Arch." Bernard L. Weiner. (With Discussion.) 1212.

"The Buttressed Dam of Uniform Strength." Herman Schorer. (With Discussion.) 666.

BEAMS.

"Analysis of Continuous Frames by Distributing Fixed-End Moments." Hardy Cross. (With Discussion.) 1.

BRIDGES.

"Design of a Reinforced Concrete Skew Arch." Bernard L. Weiner. 1212. Discussion: G. D. Houtman, J. Charles Rathbun, and A. A. Eremin. 1321.

BUTTRESSES.

"The Buttressed Dam of Uniform Strength." Herman Schorer. (With Discussion.) 666.

CAMPS.

— and facilities, Cascade Tunnel construction. 962.

CANALS.

"Flow of Water in Tidal —." Earl I. Brown. (With Discussion.) 749.

See also IRRIGATION CANALS.

CEMENT.

— tests for use on locks and dams, Ohio River. 1348.

CITY PLANNING.

"Legal Problems Involved in Establishing Set-Back Lines." Clifton Williams. (With Discussion.) 887.

CLAY.

Physical characteristics of — and shales. 629.

COMPASS.

Application of the gyro-compass to dredging work. 648.

CONCRETE.

— lining of Cascade Tunnel. 978.

"Manufacturing — of Uniform Quality." William M. Hall. 1336. Discussion: Henry B. Seaman, Theodore Belzner, John Sanford Peck, J. W. Kelly, Stanton Walker, Edward E. Bauer, O. Bonney and D. T. Mitchell, C. E. Arnold, Morris Mason, John H. Griffith, and W. B. Wendt. 1359.

Pneumatic — placing practise in the Cascade Tunnel. 993.

CONSTRUCTION PLANT.

"Construction of La Ola Pipe Line in Chile." W. B. Saunders. (With Discussion.) 230.

— , Cascade Tunnel, Great Northern Railway. 950.

"Economical Design of Hydraulic Pipe-Line Dredge." John Francis Cushing. (With Discussion.) 625.

CONTINUOUS GIRDERS.

"Analysis of Continuous Frames by Distributing Fixed-End Moments." Hardy Cross. (With Discussion.) 1.

CONTRACTORS.

Relation between engineers and —. 1381.

CONTRACTORS' PLANT.

See **CONSTRUCTION PLANT.**

COSTS OF WORK.

"Economical Design of Hydraulic Pipe-Line Dredge." John Francis Cushing. (With Discussion.) 625.

Pipe line costs. 246, 269.

Wages paid on Cascade Tunnel, Great Northern Railway. 987.

DAMS.

Construction of a model of an arch dam. 318.

"Gravity — Arched Down Stream." B. J. Lambert. 1178. Discussion: Eugene Kalman, William P. Creager, T. L. E. Haug, B. F. Jakobsen, A. Floris, and Floyd A. Nagler. 1184.

"Some Aspects of Water Conservation." R. A. Sutherland. (With Discussion.) 157.

"Stresses in Gravity — by Principle of Least Work." B. F. Jakobsen. 489. Discussion: William Cain, William Gore, L. J. Mensch, Lars R. Jorgensen, C. A. P. Turner, Donald P Barnes, Anthony Hoadley, Fred W. Ely, M. H. Gerry, Jr., Fredrik Vogt, Eugene Kalman, Fernand Campus, A. Floris, Robert E. Glover, and P. Wilhelm Werner. 514.

"The Buttressed Dam of Uniform Strength." Herman Schorer. 666. Discussion: James Girand, Fred A. Noetzli, B. F. Jakobsen, Calvin V. Davis, A. A. Eremin, Eugene Kalman, A. Floris, Fredrik Vogt, A. C. Schwager, Paul Bauman, and I. M. Nelidov. 689.

"The Don Martin Project." Andrew Weiss. (With Discussion.) 835.

See also **STRUCTURES, THEORY OF.**

DREDGES AND DREDGING.

Application of the gyro-compass to dredging work. 648.

"Economical Design of Hydraulic Pipe-Line Dredge." John Francis Cushing. 625. Discussion: R. L. Vaughn, and Arthur L. Collins. 651.

DRILLING.

Drill-steel sharpening practise at west portal, Cascade Tunnel. 989.

ENGINEERING.

"Some Reflections Regarding — Practice": Address at the Annual Convention, Yellowstone National Park, Wyoming, July 6, 1932. Herbert S. Crocker. 1380.

ENGINEERS.

Relation between — and contractors. 1381.

FLUMES.

"Tests of Broad-Crested Weirs." James G. Woodburn. (With Discussion.) 387.

FRAMEWORKS.

"Analysis of Continuous Frames by Distributing Fixed-End Moments." Hardy Cross. (With Discussion.) 1.

GROUND-WATER.

"Flow of — as Applied to Drainage Wells." M. R. Lewis. 1194. Discussion: L. Standish Hall, and O. W. Israelsen. 1207.

HIGHWAYS.

"Highway Location: General Considerations." Gibb Gilchrist. (With Discussion.) 454.

"Highway Location: Practical Considerations." A. R. Losh. (With Discussion.) 468.

HYDRAULIC JUMP.

"Tests of Broad-Crested Weirs." James G. Woodburn. (With Discussion.) 387.

Weirs with Aprons Inclined Up Stream and Down Stream. Alex. R. Webb. 408.

INSPECTION.

"Manufacturing Concrete of Uniform Quality." William M. Hall. (With Discussion.) 1336.

"Some Reflections Regarding Engineering Practice": Address at the Annual Convention, Yellowstone National Park, Wyoming, July 6, 1932. Herbert S. Crocker. 1380.

IRRIGATION.

"Measuring — Deliveries in the Panjab." E. S. Lindley. 1005.

"The Don Martin Project." Andrew Weiss. 835. Discussion: C. H. Howell, and Robert S. Stockton. 855.

IRRIGATION CANALS.

"Measuring Irrigation Deliveries in the Panjab." E. S. Lindley. 1005.

"The Don Martin Project." Andrew Weiss. (With Discussion.) 835.

LAW.

"Legal Problems Involved in Establishing Set-Back Lines." Clifton Williams. (With Discussion.) 887.

MAPPING.

See MAPS.

MAPS.

Mapping procedure, Swift River Reservoir. 1027.

MATHEMATICS.

"Theory of Similarity and Models." Benjamin F. Groat. (With Discussion.) 273.

MEMOIRS OF DECEASED MEMBERS.

Adams, Edward Dean. 1636.
Adams, Raymond Edmond. 1388.
Addis, William George. 1389.
Adey, William Henry. 1390.
Alger, Julian Wilmot. 1590.
Allen, Andrews. 1391.
Ash, Louis Russell. 1393.
Asserson, Peter Christian. 1397.
Bailey, Albert Ross. 1592.
Bailey, Frank Harrison. 1403.
Baird, Samuel Pond. 1406.
Behrend, Bernard Arthur. 1407.
Billingsley, James Wartelle. 1411.
Bisbee, Fred Milton. 1413.
Boardman, Howard Edward. 1415.
Boucher, William James. 1417.
Brackenridge, William Algernon. 1419.
Braune, Gustave Maurice. 1422.
Breckinridge, George Castleman. 1594.
Brodie, Hugh. 1426.
Bunn, Paul King. 1428.
Burden, Morton. 1595.
Burroughs, Hector Robins. 1429.
Campbell, George Raymond. 1431.
Carson, Howard Adams. 1386.
Carter, Edward Carlos. 1433.
Chipman, Willis. 1435.
Christensen, John Christian Valdemar. 1438.
Clarke, St. John. 1439.
Comly, James Retzer. 1442.
Coppée, Henry St. Leger. 1444.
Craigmile, Charles James. 1445.
Cummings, William Warren. 1447.
Dahm, Sverre. 1448.
Davidson, Frank Eugene. 1451.
Davis, Joseph Phineas. 1453.
Dawson, John Stanley. 1457.
Dessery, Floyd Gossett. 1458.
Detwiler, Harry Espenship. 1460.
Drake, Robert Morris. 1597.
Dunlap, Frederic Clark. 1461.
Easterbrooks, Preston Burt. 1597.
Edwards, James Harvey. 1463.
Ellis, George Ezra. 1466.
Elwell, Charles Clement. 1467.
Emerson, Frank Collins. 1470.

Wintermute, Ferd Clark. 1624.
Woods, Henry Dickinson. 1584.
Worthington, Charles. 1586.
Yappen, Adolph. 1588.
Zarbell, Elmer. 1589.

MODELS.

— of gravity dams arched down stream. 1178.

"Theory of Similarity and —." Benjamin F. Groat. 273. Discussion: H. Bateman, W. P. Roop, A. V. Karpov, Jasper O. Draffin, Ed S. Smith, and F. J. Eisner. 304.

MOMENTS.

"Analysis of Continuous Frames by Distributing Fixed-Ends —." Hardy Cross. (With Discussion.) 1.

PIPE.

"Construction of La Ola — Line in Chile." W. B. Saunders. (With Discussion.) 230.

PIPE LINES.

"Construction of La Ola Pipe Line in Chile." W. B. Saunders. 230. Discussion: Ernest B. Nelson, H. L. Thackwell, and William E. Rudolph. 266.

"Economical Design of Hydraulic Pipe-Line Dredge." John Francis Cushing. (With Discussion.) 625.

POWER PLANTS.

Montandon Power Station, La Ola Pipe Line. 263.

RAILROADS.

"The Eight-Mile Cascade Tunnel, Great Northern Railway": A Symposium. D. J. Kerr, Frederick Mears, and J. C. Baxter. (With Discussion.) 915.

RAINFALL.

"Formulas for — Intensities of Long Duration." Merrill M. Bernard. 592. Discussion: W. B. Gregory, W. W. Horner, Adolph F. Meyer, R. W. Powell, C. E. Grunsky, and Charles W. Sherman. 607.

REINFORCED CONCRETE.

"Design of a — Skew Arch." Bernard L. Weiner. (With Discussion.) 1212.

RESERVOIRS.

"Some Aspects of Water Conservation." R. A. Sutherland. (Wth Discussion.) 157.

"Surveys for Swift River Reservoir of the Boston Metropolitan Water Supply." N. LeRoy Hammond. (With Discussion.) 1020.

RIGHT OF WAY.

— features of highway location. 475.

RIVETED JOINTS.

Manufacture of riveted steel pipe in the field. 244.

ROADS.

"Highway Location: General Considerations." Gibb Gilchrist. 454. Discussion: C. S. Mullen, H. L. Thackwell, B. P. Harrison, and E. P. Arneson. 462.

"Highway Location: Practical Considerations." A. R. Losh. 468. Discussion: H. K. Bishop, J. C. Carpenter, H. J. Spelman, H. S. Kerr, and H. W. Giffin. 477.

RUN-OFF.

"—-Rational — Formulas." R. L. Gregory and C. E. Arnold. 1038. Discussion: LeRoy K. Sherman, Francis Bates, John W. Raymond, Jr., Reginald A. Ryves, G. S. Tapley, W. I. Hicks, Carl H. Reeves, John M. Kemmerer, Leonard L. Longacre, G. H. Hickox, Donald M. Baker, Albert R. Arledge, Clarence S. Jarvis, C. E. Grunsky, Ralph W. Powell, Merrill M. Bernard, and Charles H. Lee. 1100.

SET-BACK LINES.

See **STREET LINES.**

SHALES.

Physical characteristics of clay and —. 629.

SIMILARITY, THEORY OF.

"Theory of Similarity and Models." Benjamin F. Groat. (With Discussion.) 273.

SNOW SHEDS.

—, Great Northern Railway. 920.

SPILLWAYS.

Round-head buttress type of spillway. 855.

STREET LINES.

"Legal Problems Involved in Establishing Set-Back Lines." Clifton Williams. 887. Discussion: J. M. Albers, J. E. Willoughby, Horace H. Sears, George H. Herrold, Clifford C. Muhs, H. B. Cooley, Walter C. Sadler, H. J. McFarlan, Donald M. Baker, and E. G. Walker. 896.

STREET WIDENING.
See **STREET LINES.**

STRESS.
"Analysis of Continuous Frames by Distributing Fixed-End Moments." Hardy Cross. (With Discussion.) 1.
"Design of a Reinforced Concrete Skew Arch." Bernard L. Weiner. (With Discussion.) 1212.
"Stresses in Gravity Dams by Principle of Least Work." B. F. Jakobsen. (With Discussion.) 489.
"The Buttressed Dam of Uniform Strength." Herman Schorer. (With Discussion.) 666.

STRUCTURES, THEORY OF.
"Analysis of Continuous Frames by Distributing Fixed-End Moments." Hardy Cross. 1. Discussion: C. P. Vetter, L. E. Grinter, S. S. Gorman, A. A. Eremin, Elmer F. Bruhn, A. H. Finlay, R. F. Lyman, R. A. Caughey, Orrin H. Pilkey, I. Oesterblom, Robert A. Black, H. E. Wessman, Edward J. Bednarski, S. N. Mitra, Jens Egede Nielsen, F. E. Richart, William A. Oliver, R. R. Martel, Clyde T. Morris, Francis P. Witmer, T. F. Hickerson, F. H. Constant, W. N. Downey, E. C. Hartmann, Thomas C. Shedd, David M. Wilson, Marshall G. Findley, George E. Large, Sophus Thompson and R. W. Cutler, Alfred Gordon, A. W. Earl, A. Floris, I. M. Nelidov, E. A. MacLean, George M. Dillingham, Donald E. Larson, and J. A. Van den Broek. 11.
See also **BRIDGES.**

SURVEYING.
"Relocating Land Surveys in Texas." B. F. Williams. 735. Discussion: J. M. Howe, Arthur D. Kidder, and W. J. Powell. 744.
Surveys and sub-divisions on the Don Martin Project. 838.
Surveys, construction methods, and a comparison of routes, Cascade Tunnel. 926.
"Surveys for Swift River Reservoir of the Boston Metropolitan Water Supply." N. LeRoy Hammond. 1020. Discussion: C. B. Breed, C. L. Hall, and Frank C. Sellnow. 1029.

SURVEYING, AERIAL.
Aerial surveys for Swift River Reservoir. 1025.
"Highway Location: General Considerations." Gibb Gilchrist. (With Discussion.) 454.

TIDES.
"Flow of Water in Tidal Canals." Earl I. Brown. (With Discussion.) 749.

TRAFFIC.
"Highway Location: Practical Considerations." A. R. Losh. (With Discussion.) 468.

TRIANGULATION.
— procedure, Swift River Reservoir. 1021.

TUNNELS.
Concrete lining of Cascade Tunnel. 978.
Construction plans and methods, Cascade Tunnel. 926.
"The Eight-Mile Cascade Tunnel, Great Northern Railway": A Symposium. D. J. Kerr, Frederick Mears, and J. C. Baxter. 915. Discussion: R. H. Keays, and J. G. Sullivan. 1001.
Tunneling for La Ola Pipe Line. 256.

VENTILATION.
— of Cascade Tunnel. 958.

WATER, FLOW OF, IN OPEN CHANNELS.
"A Discharge Diagram for Uniform Flow in Open Channels." Murray Blanchard. 865. Discussion: Lynn Perry, J. B. Macphail, G. B. Pillsbury, Lynn Crandall, Benjamin E Jones, A. J. Matheson, L. Standish Hall, and Ray E. Mackenzie. 871.
"Flow of Water in Tidal Canals." Earl I. Brown. 749. Discussion: R. L. Faris, G. T. Rude, Eugene E. Halmos, W. M. Black, H. F. Flynn, and Ralph G. Davis. 814.
"Measuring Irrigation Deliveries in the Panjab." E. S. Lindley. 1005.
"Theory of Similarity and Models." Benjamin F. Groat. (With Discussion.) 273.

WATER, FLOW OF, IN PIPES.
"Economical Design of Hydraulic Pipe-Line Dredge." John Francis Cushing. (With Discussion.) 625.
"Theory of Similarity and Models." Benjamin F. Groat. (With Discussion.) 273.

WATER, FLOW OF, OVER DAMS AND WEIRS.
"Tests of Broad-Crested Weirs." James G. Woodburn. 387. Discussion: H. W. King, Sherman M. Woodward, David L. Yarnell, Boris A. Bakhmeteff, D. D. Curtis, Erik G. W. Lindquist, and Ralph L. Parshall. 417.
Weirs with Aprons Inclined Up Stream and Down Stream. Alex. R. Webb. 408.

WATER STORAGE.
"Some Aspects of Water Conservation." R. A. Sutherland. 157. Discussion: E. C. Eaton, A. W. Simonds, W. H. R. Nimmo, C. R. Olberg, John W. Pritchett, and A. J. Gilardi. 198.

WATER-WORKS.
"Construction of La Ola Pipe Line in Chile." W. B. Saunders. (With Discussion.) 230.

WAVES.
"Flow of Water in Tidal Canals." Earl I. Brown. (With Discussion.) 749.

WEIRS.
See **WATER, FLOW OF, OVER DAMS AND WEIRS.**

WELLS.
"Flow of Ground-Water as Applied to Drainage —." M. R. Lewis. (With Discussion.) 1194.

Memoir of. 1447.

CURTIS, D. D.
Tests of broad-crested weirs. 434.

CUSHING, JOHN FRANCIS.
"Economical Design of Hydraulic Pipe-Line Dredge." 625.

CUTLER, R. W.
Analysis of continuous frames. 108.

DAHM, SVERRE.
Memoir of. 1448.

DAVIDSON, FRANK EUGENE.
Memoir of. 1451.

DAVIS, CALVIN V.
Buttressed dam of uniform strength. 697.

DAVIS, JOSEPH PHINEAS.
Memoir of. 1453.

DAVIS, RALPH G.
Flow of water in tidal canals. 827.

DAWSON, JOHN STANLEY.
Memoir of. 1457.

DESSERY, FLOYD GOSSETT.
Memoir of. 1458.

DETWILER, HARRY ESPENSHIP.
Memoir of. 1460.

DILLINGHAM, GEORGE M.
Analysis of continuous frames. 125.

DOWNEY, W. N.
Analysis of continuous frames. 80.

DRAFFIN, JASPER O.
Theory of similarity and models. 326.

DRAKE, ROBERT MORRIS.
Memoir of. 1597.

DUNLAP, FREDERIC CLARK.
Memoir of. 1461.

EARL, A. W.
Analysis of continuous frames. 112.

EASTERBROOKS, PRESTON BURT.
Memoir of. 1597.

EATON, E. C.
Some aspects of water conservation. 198.

EDWARDS, JAMES HARVEY.
Memoir of. 1463.

EISNER, F. J.
Theory of similarity and models. 329.

ELLIS, GEORGE EZRA.
Memoir of. 1466.

ELWELL, CHARLES CLEMENT.
Memoir of. 1467.

ELY, FRED W.
  Stresses in gravity dams. 542.

EMERSON, FRANK COLLINS.
  Memoir of. 1470.

EMORY, LLOYD TILGHMAN.
  Memoir of. 1474.

EREMIN, A. A.
  Analysis of continuous frames. 21.
  Buttressed dam of uniform strength. 701.
  Design of a skew arch. 1327.

FARIS, R. L.
  Flow of water in tidal canals. 814.

FARNSWORTH, HOWARD RICHARDS.
  Memoir of. 1476.

FINDLEY, MARSHALL G.
  Analysis of continuous frames. 101.

FINLAY, A. H.
  Analysis of continuous frames. 23.

FLORIS, A.
  Analysis of continuous frames. 116.
  Buttressed dam of uniform strength. 710.
  Gravity dams arched down stream. 1190.
  Stresses in gravity dams. 571.

FLYNN, H. F.
  Flow of water in tidal canals. 822.

FOSTER, FRANK.
  Memoir of. 1478.

FOUGNER, HERMANN.
  Memoir of. 1480.

FUERTES, JAMES HILLHOUSE.
  Memoir of. 1482.

GAGEL, EDWARD.
  Memoir of. 1486.

GALLIVAN, JAMES HENRY.
  Memoir of. 1600.

GERRY, M. H., Jr.
  Stresses in gravity dams. 547.

GIFFIN, H. W.
  Highway location: Practical considerations. 485.

GILARDI, A. J.
Some aspects of water conservation. 220.

GILCHRIST, GIBB.
"Highway Location: General Considerations." 454.

GIRAND, JAMES.
Buttressed dam of uniform strength. 689.

GLOVER, ROBERT E.
Stresses in gravity dams. 578.

GORDON, ALFRED.
Analysis of continuous frames. 111.

GORE, WILLIAM.
Stresses in gravity dams. 520.

GORMAN, S. S.
Analysis of continuous frames. 20.

GREGORY, R. L.
"Run-Off — Rational Run-Off Formulas." 1038.

GREGORY, W. B.
Formulas for rainfall intensities. 607.

GRIFFITH, JOHN H.
Manufacturing concrete of uniform quality. 1372.

GRINTER, L. E.
Analysis of continuous frames. 11.

GROAT, BENJAMIN F.
"Theory of Similarity and Models." 273.

GRUNSKY, C. E.
Formulas for rainfall intensities. 612.
Run-off — rational run-off formulas. 1142.

HALL, C. L.
Surveys for Swift River Reservoir. 1033.

HALL, L. STANDISH.
A discharge diagram for uniform flow in open channels. 879.
Ground-water flow to wells. 1207.

HALL, WILLIAM M.
"Manufacturing Concrete of Uniform Quality." 1336.

HALLETT, JAMES HENDRICKS.
Memoir of. 1601.

HALMOS, EUGENE E.
Flow of water in tidal canals. 819.

HAMMOND, N. LEROY.
"Surveys for Swift River Reservoir of the Boston Metropolitan Water Supply." 1020.

HARDWAY, BENJAMIN HURT.
Memoir of. 1489.

HARDING, JAMES CLARK.
Memoir of. 1494.

HARRISON, B. P.
Highway location: General considerations. 464.

HARTMANN, E. C.
Analysis of continuous frames. 93.

HAUG, T. L. E.
Gravity dams arched down stream. 1188.

HEREFORD, LEWIS STIRLING.
Memoir of. 1603.

HERROLD, GEORGE H.
Legal problems in set-back lines. 901.

HICKERSON, T. F.
Analysis of continuous frames. 74.

HICKOX, G. H.
Run-off — rational run-off formulas. 1134.

HICKS, W. I.
Run-off — rational run-off formulas. 1124.

HOADLEY, ANTHONY.
Stresses in gravity dams. 539.

HORNER, W. W.
Formulas for rainfall intensities. 607.

HOUTMAN, G. D.
Design of a skew arch. 1321.

HOWE, EDWARD WILLARD.
Memoir of. 1495.

HOWE, J. M.
Relocating land surveys in Texas. 744.

HOWE, WILLIAM CHAFFIN.
Memoir of. 1603.

HOWELL, C. H.
The Don Martin project. 855.

HUGHES, THOMAS ROGERS.
Memoir of. 1625.

HUNT, ANDREW MURRAY.
Memoir of. 1497.

ISRAELSEN, O. W.
Ground-water flow to wells. 1208.

JADWIN, EDGAR.
Memoir of. 1498.

JAKOBSEN, B. F.
Buttressed dam of uniform strength. 696.
Gravity dams arched down stream. 1189.
"Stresses in Gravity Dams by Principle of Least Work." 489.

JARVIS, CLARENCE S.
Run-off — rational run-off formulas. 1140.

JENSEN, ANDREW MARTIN.
Memoir of. 1504.

JONES, BENJAMIN E.
A discharge diagram for uniform flow in open channels. 876.

JONES, WILLIAM HENRY.
Memoir of. 1505.

JORGENSEN, LARS R.
Stresses in gravity dams. 528.

KALMAN, EUGENE.
Buttressed dam of uniform strength. 703.
Gravity dams arched down stream. 1184.
Stresses in gravity dams. 556.

KARNER, WILLIAM JOSIAH.
Memoir of. 1630.

KARPOV, A. V.
Theory of similarity and models. 308.

KEAYS, R. H.
Cascade Tunnel, Great Northern Railway. 1001.

KEHOE, ALFRED LAWRENCE.
Memoir of. 1506.

KELLY, J. W.
Manufacturing concrete of uniform quality. 1361.

KEMMERER, JOHN M.
Run-off — rational run-off formulas. 1127.

KERR, D. J.
"The Eight-Mile Cascade Tunnel, Great Northern Railway: Preliminary Studies and Results of Improving Cascade Crossing." 917.

KERR, H. S.
Highway location: Practical considerations. 483.

KIDDER, ARTHUR D.
Relocating land surveys in Texas. 745.

KIEL, FRANK BURDETTE.
Memoir of. 1604.

KING, H. J.
Drill-steel sharpening practise at West Portal, New Cascade Tunnel. 989.
Pneumatic concrete placing practise in the New Cascade Tunnel. 993.

KING, H. W.
Tests of broad-crested weirs. 417.

KONDO, SENTARO.
Memoir of. 1507.

LAMBERT, B. J.
"Gravity Dams Arched Down Stream." 1178.

LARGE, GEORGE E.
Analysis of continuous frames. 101.

LARSON, DONALD E.
Analysis of continuous frames. 127.

LAWSON, ELMER BARTHOLD.
Memoir of. 1626.

LAWTON, WILLIAM HENRY.
Memoir of. 1508.

LEE, CHARLES H.
Run-off — rational run-off formulas. 1161.

LELAND, GEORGE HERBERT.
Memoir of. 1510.

LEWIS, M. R.
"Flow of Ground-Water as Applied to Drainage Wells." 1194.

LINDLEY, E. S.
"Measuring Irrigation Deliveries in the Panjab." 1005.

LINDQUIST, ERIK G. W.
Tests of broad-crested weirs. 435.

LITTLE, CLIFFORD F.
Making and seasoning concrete test cylinders in the field. 1353.

LONGACRE, LEONARD L.
Run-off — rational run-off formulas. 1128.

LOSH, A. R.
"Highway Location: Practical Considerations." 468.

LYMAN, R. F.
Analysis of continuous frames. 27.

MacDIARMID, MILO STUART.
Memoir of. 1511.

MACKENZIE, RAY E.
A discharge diagram for uniform flow in open channels. 880.

MacLEAN, E. A.
Analysis of continuous frames. 123.

MACPHAIL, J. B.
A discharge diagram for uniform flow in open channels. 873.

McBETH, R. W.
Inspection of concrete construction. 1354.

McCULLOUGH, ERNEST.
Memoir of. 1512.

McFARLAN, H. J.
Legal problems in set-back lines. 907.

MAILEY, JOHN BRUCE.
Memoir of. 1607.

MARSHALL, HORACE MILLER.
Memoir of. 1514.

MARTEL, R. R.
Analysis of continuous frames. 60.

MASON, MORRIS.
Manufacturing concrete of uniform quality. 1371.

MATHESON, A. J.
A discharge diagram for uniform flow in open channels. 878.

MEARS, FREDERICK.
"The Eight-Mile Cascade Tunnel, Great Northern Railway: Surveys, Construction Methods, and a Comparison of Routes." 926.

MEIGS, MONTGOMERY.
Memoir of. 1516.

MENSCH, L. J.
Stresses in gravity dams. 524.

MERICKEL, BERNARD JOSEPH.
Memoir of. 1627.

METCALFE, JOSEPH DAVIS.
Memoir of. 1518.

MEYER, ADOLPH F.
Formulas for rainfall intensities. 608.

MILLER, JOHN HARRY.
Memoir of. 1628.

MIRICK, ALFRED STOWE.
Memoir of. 1608.

MITCHELL, D. T.
Manufacturing concrete of uniform quality. 1365.

MITRA, S. N.
Analysis of continuous frames. 55.

MOLERA, EUSEBIUS JOSEPH.
Memoir of. 1520.

MONTFORT, RICHARD.
Memoir of. 1521.

MORRIS, CLYDE T.
Analysis of continuous frames. 66.

MUHS, CLIFFORD C.
Legal problems in set-back lines. 902.

MULLEN, C. S.
Highway location: General considerations. 462.

MURPHY, JOSEPH LINCOLN.
Memoir of. 1609.

NAGLER, FLOYD A.
Gravity dams arched down stream. 1191.

NELIDOV, I. M.
Analysis of continuous frames. 117.
Buttressed dam of uniform strength. 716.

NELSON, ERNEST B.
La Ola pipe line, Chile. 266.

NIELSEN, JENS EGEDE.
Analysis of continuous frames. 55.

NIMMO, W. H. R.
Some aspects of water conservation. 207.

NOETZLI, FRED A.
Buttressed dam of uniform strength. 692.

NOYES, STEPHEN HENLEY.
Memoir of. 1521.

ODELL, FREDERICK SYLVESTER.
Memoir of. 1524.

OESTERBLOM, I.
Analysis of continuous frames. 32.

OLBERG, C. R.
Some aspects of water conservation. 212.

OLIVER, WILLIAM A.
Analysis of continuous frames. 60.

ONDERDONK, ARTHUR.
Memoir of. 1525.

PARDEE, ROBERT McKNIGHT.
Memoir of. 1614.

PARSHALL, RALPH L.
Tests of broad-crested weirs. 440.

PECK, JOHN SANFORD.
Manufacturing concrete of uniform quality. 1360.

PERRY, LYNN.
A discharge diagram for uniform flow in open channels. 871.

PHELPS, WILLIAM COLLINS.
Memoir of. 1527.

PILKEY, ORRIN H.
Analysis of continuous frames. 29.

PILLSBURY, G. B.
A discharge diagram for uniform flow in open channels. 873.

PORTER, HENRY TEGMEYER.
Memoir of. 1528.

POWELL, R. W.
Formulas for rainfall intensities. 609.
Run-off — rational run-off formulas. 1149.

POWELL, W. J.
Relocating land surveys in Texas. 745.

PRESTON, HARRY LONGYEAR.
Memoir of. 1531.

PRITCHETT, JOHN W.
Some aspects of water conservation. 215.

RANDOLPH, WILLIAM COUTS, Jr.
Memoir of. 1615.

RATHBUN, J. CHARLES.
Design of a skew arch. 1323.

RAYMER, ALBERT REESOR.
Memoir of. 1534.
